Density of paths of iterated Lévy transforms of Brownian motion

Marc Malric

June 24, 2009

Abstract: The Lévy transform of a Brownian motion $B$ is the Brownian motion $B'_t = \int_0^t \text{sgn}(B_s) dB_s$. Call $T$ the corresponding transformation on the Wiener space $W$. We establish that a.s. the orbit of $w \in W$ under $T$ is dense in $W$ for the compact uniform convergence topology.
1 Lévy raisings, B-raised Brownian motions and related tools.

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be the probability space where all random elements are defined, and $(\text{W}, \mathcal{W}, \pi)$ the Wiener space. Any measurable map from $\Omega$ to any measure space, defined $\mathbb{P}$-a.e., will be called a random variable. If $X$ is a r.v. with values in some measurable space $A$, the probability measure $\mathbb{P}$ on $A$ is called the law of $X$, and denoted by $\mathcal{L}(X)$. For instance, a $\text{W}$-valued r.v. with law $\pi$ is a Brownian motion.

The Lévy transform $T : W \to W$ is defined $\pi$-a.e. and preserves $\pi$. Given a Brownian motion $B$, we denote by $B^n$ its $n$-Lévy iterate, that is, the Brownian motion $B^n = T^n \circ B$.

From now on, $T > 0, \varphi \in C([0, T], \mathbb{R})$ and $\varepsilon > 0$ are fixed, and $B$ a Brownian motion. The goal is to prove that the event $E = E^\varepsilon = \{\forall n \geq 0, \|B^n - \varphi\|_\infty > \varepsilon\}$ is negligible, where $\|f\|_\infty = \|f\|_{[0, T]}$. It suffices in fact to show $\mathbb{P}(E) < \varepsilon$, because $E^{\varepsilon_1} \subseteq E^{\varepsilon_2}$ when $\varepsilon_2 < \varepsilon_1$.

The idea is to construct from $B$ another stochastic process $\Gamma : \Omega \to W$, which depends on $T, \varphi$ and $\varepsilon$, and has the following three properties:

(i) The law of the process $\Gamma$, i.e., the probability $F \to \mathbb{P}(\Gamma^{-1}F)$ on $(W, \mathcal{W})$, is absolutely continuous w.r.t. the law $\pi$ of $B$.

(ii) For some deterministic $r \geq 0$, one has $\Gamma^r = B^r$, that is, $T^r \circ \Gamma = T^r \circ B$.

(iii) $\mathbb{P}(\forall n \geq 0\|\Gamma^n - \varphi\|_\infty > \varepsilon) < \varepsilon$.

Property (i) implies that $T \circ \Gamma$ can be (almost everywhere) defined, in spite of $T$ not being everywhere defined. Indeed, if $T' : W \to W$ is another version of $T$, that is if $T' = T$ a.e., the set $\{T' \neq T\}$ is $\pi$-negligible; hence, by (i), $\Gamma^{-1}\{T' \neq T\}$ is $\mathbb{P}$-negligible, and $T' \circ \Gamma = T \circ \Gamma$ a.s. Similarly, one can define the stochastic processes $\Gamma^n = T^n \circ \Gamma$, which verify $\Gamma^0 = \Gamma$ and $T \circ \Gamma^n = \Gamma^{n+1}$.

**Proposition 1.** For fixed $G \in \mathcal{W}$ and $\varepsilon > 0$, let us suppose that there exists a stochastic process $\Gamma : \Omega \to W$ satisfying properties (i), (ii) and

\[(1) \quad \mathbb{P}(\forall n \geq 0, \Gamma^n \in G) < \varepsilon.\]

Then:

\[(2) \quad \mathbb{P}(\forall n \geq 0, B^n \in G) < \varepsilon.\]
Proof. Take $G \in \mathcal{W}$ and put $F = \bigcap_{n \geq 0} T^{-n}G$. Then, for $r \geq 0$,

$$T^{-r}F = \bigcap_{n \geq r} T^{-n}G \supset \bigcap_{n \geq 0} T^{-n}G = F.$$  

But these two sets, $F$ and $T^{-r}F$, included in one another, have the same \(\pi\)-probability by $T$–invariance; so equality $F = T^{-r}F$ holds up to $\pi$–negligibility. As the laws of $\Gamma$ and $B$ are absolutely continuous w.r.t. $\pi$ (this is where (i) is used), we have $\Gamma^{-1}(F) = \Gamma^{-1}(T^{-r}F)$ and $B^{-1}F = B^{-1}(T^{-r}F)$ up to $P$–negligible events. In other words, almost surely, we have $\{\Gamma \in F\} = \{\Gamma^r \in F\}$ and $\{B \in F\} = \{B^r \in F\}$. Consequently, choosing $r$ given by (ii) and using $\Gamma^r = B^r$, we have $\{\Gamma \in F\} = \{B \in F\}$ a.s. That is to say:

$$P(\forall n \geq 0, \Gamma^n \in G) = P(\forall n \geq 0, B^n \in G)$$

Specializing $G = \{w \in \mathcal{W} ; \|w - \varphi\|_\infty > \varepsilon\}$, we obtain:

$$P(E) < \varepsilon$$

Proposition 1 reduces the proof of the approximation theorem to the construction of a process $\Gamma$ verifying (i), (ii), and (iii). We shall first choose $r$ in a suitable way, then work backwards, in $r$ steps, from $\Gamma^r = B^r$ to $\Gamma = \Gamma^0$; each step (called a Lévy raise) will construct $\Gamma^{n-1}$ from its Lévy transform $\Gamma^n = T \circ \Gamma^{n-1}$. The sequence $⟨\Gamma^r, \Gamma^{r-1}, ..., \Gamma^0⟩$ is given a name:

**Definition 1.** Given $r \in \mathbb{N}$, a sequence $⟨\Gamma^r, \Gamma^{r-1}, ..., \Gamma^0⟩$ is called a sequence of $B$–raised Brownian motions of index $r$ if each $\Gamma^n$ is a $\mathcal{W}$–valued r.v. with law absolutely continuous w.r.t. $\pi$, if $\Gamma^r = B^r$, and if we have $\Gamma^n = T \circ \Gamma^{n-1}$ for $0 < n \leq r$.

In fact, for convenience of exposition, let us enlarge the filtered probability space $\Omega$, we suppose it contains the whole sequence $(B^n)_{n \in \mathbb{N}}$ of the Brownian iterates of $B'$, B.M. independent from $B$.

So we can assert:

**Corollary 1.** To prove the approximation theorem, it suffices to exhibit a sequence $⟨\Gamma^r, \Gamma^{r-1}, ..., \Gamma^0⟩$ of $B$–raised Brownian motions of index $r$ such that

$$P(\|\Gamma^n - \varphi\|_\infty < \varepsilon \text{ for some } n \in \{0, ..., r\}) > 1 - \varepsilon.$$
**Proof** Properties (i) and (ii) of Proposition 1 are granted by the definition of a sequence of $B$-raised Brownian motions, and (iii) is implied by (1).

A Lévy raise starts with a given $W$-valued r.v. $\Gamma^n$, and yields some r.v. $\Gamma^n$ with Lévy transform $\Gamma^n$. Given a $W$-valued r.v. $V$, how can one find a r.v. $U$ such that $V = T \circ U$? Knowing $V$ is equivalent to knowing $|U|$, so to define $U$ one only needs to decide which sign is assigned to each excursion of $|U|$ away from zero. To make this rigorous, we need a formal definition of the excursions of a path and of their signs.

**Notation 1.** For $w \in W$ and $q > 0$, denote by $Z(w) = \{s \geq 0/w(s) = 0\}$ the set of zeros of $w$, and define $g_q(w) = \sup ([0, q] \cap Z(w)) \geq 0$ (last zero before $q$) and $d_q(w) = \inf ([q, \infty] \cap Z(w)) \neq \infty$ (first zero after $q$).

Fix a dense sequence $(q_n)$ in $[0, \infty]$. To each $w \in W$, we can attach the sequence $(e_p)$ of disjoint, open intervals obtained from the sequence

$$(6) \quad ((g_{q_1}, d_{q_1}), (g_{q_2}, d_{q_2}), \ldots, (g_{q_n}, d_{q_n}), \ldots)$$

by deleting an interval whenever it already occurs earlier in the sequence. The $e_p$ are the excursion intervals of $w$: almost surely, there are infinitely many of them, and they are the connected components of the open set $[0, \infty) \setminus Z(w)$. The interval $e_p(w)$ will be called the $p$-th excursion interval of $w$; $e_p$ is an interval-valued measurable map, defined on $(W, W)$ up to $\pi$-negligibility.

Since $w$ does not vanish on $e_p(w)$, its sign is constant on this interval; this sign will be denoted by $S_p(w)$, and the sequence $(S_p)$ will be called $S$. If $B$ is a Brownian motion, the sequence of r.v. $S \circ B = (S_p \circ B)$ is a coin-tossing; this means, it is an i.i.d. sequence, with each r.v. $S_p \circ B$ uniformly distributed on the set $\{-1, +1\}$. Moreover, $S_p \circ B$ and $|B|$ are independent. (See Chap. XII of [R,Y]).

**Lemma 1.** Define $I : W \rightarrow W$ by $I(w)(s) = \inf_{[0, s]} w$; that is, $|w| = Tw - ITw$ for $\pi$-a.a. $w$.

**Proof** Fix $s \geq 0$. On $[0, s]$, $B^1 = |B| - L \geq -L_{s} = L_{s} = B^1_{y_{s}}$. So $B^1_{y_{s}} = \inf_{[0, s]} B^1$, and $|B_s| = B^1_{s} + L_s = B^1_{s} - \inf_{[0, s]} B^1$. 

4
Notation 2. If \( f \) is a continuous function on \([u, v]\), we call \( \arg \min_{[u, v]} f \), resp. \( \arg \max_{[u, v]} f \), the largest \( t \in [u, v] \) such that \( f(t) = \min_{[u, v]} f \), resp. \( f(t) = \max_{[u, v]} f \).

Lemma 2. Let \( A, A' \) and \( A'' \) be three measure spaces; let \( \mu_1 \) and \( \mu_2 \) be two measures on \( A \), \( f \) a measurable map from \( A \) to \( A' \), and \( \nu \) a measure on \( A'' \). If \( \mu_1 \ll \mu_2 \), then

(i) \( \mu_1 \circ f^{-1} \ll \mu_2 \circ f^{-1} \);

(ii) \( \mu_1 \otimes \nu \ll \mu_2 \otimes \nu \).

Proof (i) If \( F \subset A' \) is measurable and if \((\mu_2 \circ f^{-1})(F) = 0\), then \( \mu_2(f^{-1}F) = 0 \), so \( \mu_1 \circ f^{-1}(F) = \mu_1(f^{-1}F) = 0 \).

(ii) If a measurable subset \( F \) of \( A \times A'' \) is negligible for \( \mu_2 \otimes \nu \), then \( \nu \)-almost all its sections \( F_y \) verify \( \mu_2(F_y) = 0 \). Hence they also verify \( \mu_1(F_y) = 0 \), and consequently \( (\mu_1 \otimes \nu)(F) = \int \mu_1(F_y)\nu(dy) = 0 \).

Lemma 3. Let \( \tau = (\tau_p) \) be coin-tossing, \( \tau' = (\tau_0') \) a r.v. with values in \( \{-1, 1\}^\mathbb{N} \) such that \( \tau'_p = \tau_p \) for all but a.s. finitely many \( p \), and \( X \) a r.v. independent of \( \tau \).

Then \( \mathcal{L}(X, \tau') \ll \mathcal{L}(X, \tau) \).

This lemma says that changing finitely many values of \( \tau \) does not perturb too much the joint law of \( X \) and \( \tau \). For instance, it implies that a process obtained from a Brownian motion by changing the signs of finitely many excursions has a law absolutely continuous w.r.t. \( \pi \). This is called ‘principe de retournement des excursions’ in [M].

Proof If \( u = (u_1, u_2, ...) \) is an infinite sequence, denote by \( u_p \) the finite sequence \( (u_1, \ldots, u_p) \) and by \( u_{[p+1]} \) the infinite sequence \( (u_{p+1}, u_{p+2}, ...) \). We have \((x,u) = f_{p}(x,u_p),u_{[p+1]} \) for some function \( f_{p} \).
We have to show that if \( F \) is measurable set such that \( \mathbf{P}[(X, \tau) \in F] = 0 \), then \( \mathbf{P}[(X, \tau') \in F] = 0 \). So assume \( \mathbf{P}[(X, \tau) \in F] = 0 \). For \( p \in \mathbb{N} \), since \( \tau_p \) takes values in \( \{-1, 1\}^p \), we can write

\[
(7) \quad \sum_{\sigma \in \{-1, 1\}^p} \mathbf{P} \left[ f_p(X, \sigma, \tau_{p+1}) \in F \text{ and } \tau_p = \sigma \right] = \mathbf{P} \left[ (X, \tau) \in F \right] = 0.
\]

Using the independence of \( \tau_p \) and \( (X, \tau_{p+1}) \), this becomes:

\[
(8) \quad \sum_{\sigma \in \{-1, 1\}^p} 2^{-p} \mathbf{P} \left[ f_p(X, \sigma, \tau_{p+1}) \in F \right] = 0;
\]

So for each \( p \in \mathbb{N} \) and each \( \sigma \in \{-1, 1\}^p \), the event \( \{f_p(X, \sigma, \tau_{p+1} \in F)\} \) is negligible. Since \( \tau_p'(\omega) = \tau_p(\omega) \) for all \( p \) larger than some \( N(\omega) \), one has

\[
\mathbf{P} \left[ (X, \tau') \in F \right] = \lim_{p \to \infty} \mathbf{P} \left[ (X, \tau') \in F \text{ and } \tau_{p+1}' = \tau_{p+1} \right] = \lim_{p \to \infty} \sum_{\sigma \in \{-1, 1\}^p} \mathbf{P} \left[ f_p(X, \sigma, \tau_{p+1}) \in F \text{ and } \tau_p' = \sigma \text{ and } \tau_{p+1}' = \tau_{p+1} \right].
\]

This is null because the event \( f_p(X, \sigma, \tau_{p+1}) \in F \) is negligible, as shown above.

\[\blacksquare\]

**Proposition 2. (mechanism of a Lévy raise)**

Suppose given the following three r.v.:

(i) \( V \), a \( \mathbf{W} \)-valued r.v., such that \( \mathcal{L}(V) \ll \pi \);

(ii) \( \tau = (\tau_p)_{p \in \mathbb{N}} \), a coin-tossing independent of \( V \);

(iii) \( \tau' = (\tau'_p)_{p \in \mathbb{N}} \), a r.v. valued in \( \{-1, 1\}^\mathbb{N} \), such that the random set \( \tau'_p(\omega) \neq \tau_p(\omega) \) is a.s. finite.

Then there exists a unique \( \mathbf{W} \)-valued r.v. \( U \) such that

\[
(9) \quad |U| = V - \mathbf{1} \circ V \text{ and } \mathbf{S}_p \circ U = \tau'_p \text{ for each } p.
\]

It is measurable w.r.t. the \( \sigma \)-field \( \sigma(V, \tau') \) and we have \( \mathcal{L}(U) \ll \pi \) and \( \mathbf{T}_0 U = V \). For any \( n \geq 0 \), we have \( U = B^{n+1} \) on the event \( \{V = B^{n+1} \text{ and } \tau' = \mathbf{S} \circ B^n\} \).
**Proof** We start from \( \mathcal{L}(V) \ll \pi = \mathcal{L}(B) = \mathcal{L}(B^1) \). Using Lemma 2 (i) we write \( \mathcal{L}(V, V - I \circ V) \ll \mathcal{L}(B^1, B^1 - I \circ B^1) \). By Lemma 2 (ii), the coin-tossing \( \tau \) (resp. \( S \circ B \)) which is independent of \( V \) (resp. \( B^1 \)) can be added on the left (resp. right), and we obtain \( \mathcal{L}(V, V - I \circ V, \tau) \ll \mathcal{L}(B^1, B^1 - I \circ B^1, S \circ B) \); by Lemma 1, the right-hand side is \( \mathcal{L}(B^1, |B|, S \circ B) \). Lemma 3 allows us to replace \( \tau \) by \( \tau' \) in the left-hand side, so we finally have

\[
\mathcal{L}(V, V - I \circ V, \tau) \ll \mathcal{L}(B^1, |B|, S \circ B) \tag{10}
\]

Now, we call \( W^+ \) the set of non-negative paths and \( f : W^+ \times \{-1, 1\}^N \rightarrow W \) the measurable function such that \( w = f([w], S(w)) \). We remark that \( B = f(|B|, S \circ B) \) and we define \( U = f(V - I \circ V, \tau') \); this is the unique r.v. \( U \) such that \( \|U\| = V - I \circ V \) and \( S \circ U = \tau' \). To verify that \( \mathcal{L}(U) \ll \pi \) and \( T \circ U = V \), we apply Lemma 2 (i) to (2) with the functions \( g(x, y, \sigma) = f(y, \sigma) \) and \( h(x, y, \sigma) = (f(y, \sigma), x) \). With \( g \) we obtain \( \mathcal{L}(U) \ll \mathcal{L}(B) \), the first claim. With \( h \) we obtain \( \mathcal{L}(U, V) \ll \mathcal{L}(B, B^1) \); this implies \( T \circ U = V \) since the joint law \( \mathcal{L}(B) \), \( (B^1) \) is carried by the graph of \( T \).

Last, on the event \( \{V = B^{n+1} and \tau' = s \circ B^n\} \), using the definition of \( U \) and Lemma 1 we have

\[
U = f(V - I \circ V, \tau') = f(B^{n+1} - I \circ B^{n+1}, S \circ B^n) = f(|B^n|, S \circ B^n) = B^n. \tag{11}
\]

\[\]  

**Proposition 3.** Denote by \( P_f(\mathbb{N}) \) the set of all finite subsets of \( \mathbb{N} \). Fix \( r \) in \( \mathbb{N} \). For each \( n \leq r \), let be given \( N^n \), a r.v. with values in \( P_f(\mathbb{N}) \), and \( \Sigma^n = (\Sigma^n_p, p \in N^n) \), a r.v. taking its values in \( \bigcup_{M \in P_f(\mathbb{N})} \{-1, 1\}^M \), such that \( \Sigma^n(\omega) \in \{-1, 1\}^{N^n(\omega)} \).

Starting with \( \Gamma' = B' \), we can define a sequence \( (\Gamma^n)_{n \leq r} \) such that \( \Gamma^{n-1} \) is the \( W \)-valued r.v. \( U \) obtained in Proposition 2 from

\[
V = \Gamma^n, \quad \tau = S \circ B^{n-1}, \quad \tau'_p = \begin{cases} 
\Sigma^n_p(\omega) & \text{if } p \in N^n(\omega) \\
\tau_p(\omega) & \text{else}
\end{cases}
\]

Then the sequence \( (\Gamma^n)_{n \leq r} \) is a \( B \)-ruised Brownian motions of index \( r \).

**Proof** First, we verify that the \( \Gamma^n \) can be constructed stepwise. Assuming \( \Gamma^n \) has already been constructed, has a law absolutely continuous w.r.t. \( \pi \),
Proposition 2 applies to \( V = \Gamma^{n-1} \) and \( \tau = S \circ B^{m-1} \) (they are independent. The r.v. \( \Gamma^{n-1} = U \) yielded by Proposition 2 also satisfies \( \mathcal{L}(\Gamma^{n-1}) \ll \pi \), and is measurable in \( \sigma(F, \tau') \).

The rest of the proof will exhibit a sequence \( (\Gamma^n)_{n \geq r} \) of B-raised motions such that \( \Gamma^{J-n} = C^n \). Starting with \( \Gamma^r = B^r \), the other \( \Gamma^m \) will be inductively defined: if \( m < r \), suppose \( \Gamma^{m+1} \) has been defined, is \( \sigma(B^{m+1}) \)-measurable, and verifies \( \mathcal{L}(\Gamma^{m+1}) \ll \pi \); define \( \Gamma^m \) as the r.v. \( U \) obtained in Proposition 2 from

\[
V = \Gamma^{m+1}, \quad \tau = S \circ B^m, \quad \tau'_p = \begin{cases} 
\Sigma^{J-m}_\omega & \text{if } p \in N^{J-m}_\omega \\
\tau_p(\omega) & \text{else}
\end{cases}
\]

This is possible since \( V \) and \( \tau \) are independent and \( N^{J-m-1} \) is a.s. finite; the result \( \Gamma^m \) verifies \( \mathcal{L}(\Gamma^n) \ll \pi \) and \( T \circ \Gamma^m = \Gamma^{m+1} \). To show that \( \Gamma^m \) is \( \sigma(B^m) \)-measurable, it suffices to show that so is \( \tau' \); this may be done separately on each of the events \( \{J \leq m\}, \{J = m+1\}, \ldots, \{J = r\} \), because they form a \( \sigma(B^m) \)-partition of \( \Omega \). On \( \{J \leq m\} \), we have \( \tau' = S \circ B^m \); this is \( \sigma(B^m) \)-measurable. To see what happens for other values of \( j \), introduce \( \phi^n \) and \( \psi^n \) such that \( N^n = \phi^n(B^{J-n}) \) and \( \Sigma^n = \psi^n(B^{J-n}) \) for \( 0 \leq n < k \).

For \( j \in \{m+1, \ldots, m+k\} \), we have on \( \{J = j\} \)

\[
\tau' = \psi^n(B^{J-n}) \mathbb{I}_{\phi^n(B^{J-n})} + \tau \left( \mathbb{I}_{\Omega} - \mathbb{I}_{\psi^n(B^{J-n})} \right)
\]

This is \( \sigma(B^m) \)-measurable too. We have established that \( \Gamma^r, \ldots, \Gamma^0 \) exist and form a sequence of \( B \)-raised motions; it remains to see that \( \Gamma^{J-n} = C^n \).

This is done in two steps. Firstly, by induction on \( m \), we have \( \Gamma^m = B^m \) on \( \{J \leq m\} \) : this holds for \( m = r \), and if it holds for \( m + 1 \), it holds for \( m \) too, owing to the last statement in Proposition 1. Consequently, \( \Gamma^m = B^m \) on \( \{J = m\} \), that is \( \Gamma^J = B^J = C^0 \). Secondly, to proceed by induction on \( n \), we will assume that \( \Gamma^{J-n} = C^n \) for some \( n \geq 0 \), and show \( \Gamma^{J-n-1} = C^{n+1} \). It suffices to show this equality on the event \( \{J = j\} \); on this event, using the definition of \( \Gamma^m \) with \( m = j - n - 1 \) and the inequality \( m = j - n - 1 < j \), the r.v. \( \Gamma^{J-n-1} \) satisfies both \( T(\Gamma^{j-n}) = \Gamma^{j-n} = C^n = T(C^{n+1}) \) and

\[
S \circ \Gamma^{J-n-1} = \begin{cases} 
\Sigma^{n+1} & \text{on } \mathcal{N}^n \\
S \circ B^{j-n-1} & \text{else}
\end{cases}
= S \circ C^{n+1}.
\]

These two equalities entail \( \Gamma^{J-n-1} = C^{n+1} \) a.s. on \( \{J = j\} \).
**Lemma 4.** Let \((j, k) \in \mathbb{N}^2\) and \(Q\) and \(R\) be two r.v. such that \(k \leq j - 1\) and \(0 \leq Q \leq R\). On the event \(\{\forall n \in \{k, \ldots, j - 1\} Z \circ B^n \cap (Q, R) = \emptyset\}\) that the first iterates of \(B\) do not vanish between \(Q\) and \(R\), there exists a (random) isometry \(i : \mathbb{R} \rightarrow \mathbb{R}\) such that \(B^j = i \circ B^k\) on the interval \((Q, R)\).

**Proof** By induction, it suffices to show that if \(B^j\) does not vanish on the interval \((Q, R)\), then \(B^j = i \circ B^j\) on \((Q, R)\), for some random isometry \(i\). This is just Lemma 5 with \(j = k + 1\) and \(B^j\) instead of \(B^k\), so we may suppose that \(j = 1\).

On the event \(\{Q = R\}\), the result is trivial. On \(\{Q < R\} \cap \{Z \circ B \cap (Q, R) = \emptyset\}\), the local time \(L\) is constant on \((Q, R)\) because its support is \(Z \circ B\), and the sign of \(B\) is constant on \((Q, R)\); so \(B^1 = |B| - L = i(B)\) on \((Q, R)\), where \(i\) is the random isometry \(x \mapsto x \text{sgn}(B_{(Q+R)/2}) - L_{(Q+R)/2}\).

\[\blacksquare\]

**Notation 3.** For \(w \in \mathcal{W}\), the \(p\)-th excursion interval \(e_p(w)\) was defined earlier; the number \(h_p(w) = \max_{s \in e_p(w)} |w(s)|\) will be called the height of the corresponding excursion.

**Lemma 5.** Let \(X\) be a process whose law is absolutely continuous w.r.t. Wiener measure. Almost surely,

- \(\lim_{p \to \infty} h_p(X) \mathbb{1}_{\{e_p(X) \subset [0,t]\}} = 0\);
- \(\sum_{p \in \mathbb{N}} h_p(X) \mathbb{1}_{\{e_p(X) \subset [0,t]\}} = \infty\);
- \(\{\sum_{p \in \mathcal{M}} h_p(X) \mathbb{1}_{\{e_p(X) \subset [0,t]\}}, \mathcal{M} \in \mathcal{P}_f(\mathbb{N})\}\) is dense in \([0, \infty)\);
- between any two different excursions of \(X\), there exists a third one, with height smaller than any given random variable \(\eta > 0\).

**Proof** By a change of probability, we may suppose that \(X\) is a Brownian motion. It is known (see Exercise (VI.1.19) of [RY]) that when \(\eta \to 0^+\), the number \(\sum_{p} \mathbb{1}_{\{e_p(X) \subset [0,t]\}} \mathbb{1}_{\{h_p(X) > \eta\}}\) of downcrossings of the interval \([0, \eta]\) by \(|X|\) before \(t\) is a.s. equivalent to \(\eta^{-1} L_t\), where \(L_t\) is the local time of \(X\).
at 0. This easily implies (i) and (ii), wherefrom (iii) follows. Last, between any two excursions of \(X\) there are infinitely many other ones (because \(X\) has no isolated zeroes) and, by (i), only finitely many with heights above \(\eta\), whence (iv).

\[\square\]

**Notation 4.** An excursion whose interval is included in \([0,t]\) will be called a \(t\)-excursion.

It remains to describe the \(\mathcal{N}^n\) and \(\Sigma^n\), i.e., to choose the signs of finitely many excursions when \(\text{Lévy-raising from } \Gamma^n\text{ to } \Gamma^{n-1}\). This will be done soon; we first need some notation and a lemma.

**Notation 5.** If \(e'\) and \(e''\) are two excursions of a path (or of a process), \(e' < e''\) means that \(e'\) is anterior to \(e''\): \(s' < s''\) for all \(s' \in e'\) and \(s'' \in e''\). For an excursion \(e\) of \(w\), we denote by \(i_w e := \inf\{w_s; s \in [0, d_w]\}\).

**Definition 2.** An excursion \(e\) of a path \(w \in W\) is said to be tall if it is positive (this implies that the process \(\text{Iw} \text{ remains constant during } e\)); and if for any excursion \(e'\) of \(w\) such that \(i_w e' = i_w e\) and higher than \(e\), then \(e' = e\). Formally, \(e\) is tall if it is positive and if

\[
\max(w(s); s \geq 0, (\text{Iw})(s) = i_w e) = \max(w(s); s \in e).
\]

**Lemma 6.** Let \(\eta\) be a positive number, \(m \geq 1\) be an integer and \(w \in W\) a path. Let \(e_1, \ldots, e_{m+1}\) be \(m + 1\) different \(t\)-excursions of \(w\), numbered in chronological order: \(e_1 < \cdots < e_{m+1}\); call \(h_1, \ldots, h_{m+1}\) their respective heights. Let \(f_1, \ldots, f_p\) denote all excursions of \(w\) which are anterior to \(e_{m+1}\) and whose heights are \(\geq \min(\eta, h_1, \ldots, h_{m+1})\), numbered in reverse chronological order: let \(g_1, \ldots, g_p\) be \(p\) excursions of \(w\) verifying \(f_p < g_p < \cdots < f_1 < g_1 < e_{m+1}\). Suppose that

- the excursion \(e_{m+1}\) is negative, and all \(t\)-excursions higher than \(e_{m+1}\) are positive;
- the excursions \(f_1, \ldots, f_p\) are positive;
• the excursions $g_1, \ldots, g_p$ are negative; and every negative excursion anterior to $g_p$ is smaller than $g_q$.

We call the $g_i$'s the plug-excursions, and the $e_j$'s the protected excursions. Then $e_1, \ldots, e_m$ are tall, and $|i_w e_1| < |i_w e_2| < \cdots < |i_w e_m| < \eta$.

**Proof** Firstly, $|i_w f_1| < \eta$ because $f_1 < e_{m+1}$ and any excursion anterior to $e_{m+1}$ and having height $\geq \eta$ is one of the $f_q$, hence positive.

Secondly, for $1 \leq q \leq p$, the excursion $g_q$ is negative and higher than any negative excursion, anterior to it; so $I_w$ is not constant during $g_q$, and consequently we have

$$|i_w f_p| < |i_w f_{p-1}| < \cdots < |i_w f_1| < \text{height of } g_1,$$

where each $<$ sign is due to $I_w$ varying on the corresponding $g_q$.

Thirdly, combining (20) with $|i_w f_1| < \eta$ (first step), and noticing that, by definition of the $f_q$, $(e_1, \ldots, e_m)$ is a sub-sequence of $(f_p, \ldots, f_1)$, we obtain

$$|i_w e_1| < \cdots < |i_w e_m| < \eta.$$

Last, it remains to establish that $e_l$ is tall for $1 \leq l \leq m$. Let $e'$ denote a positive excursion of $w$ with height $h' \geq h_l$ and such that $i_w e' = i_w e_l$. From (13), we have $|i_w e'| = |i_w e_l| < \text{height of } g_l$; so $e'$ is anterior to $g_l$ and a fortiori anterior to $e_{m+1}$. As $h' \geq h_l$, $e'$ must be one of the $f_q$ (see their definition). But $e_l$ is also one of the $f_q$ and, due to (13), all $i_w f_q$ are different; so $e' = e_l$. This means that $e_l$ is tall.

In the proof of Lemma 6, the negative excursions $g_q$ are used to separate the $f_q$ from each other. Yet, in the end, we are not interested in the behavior of all $f_q$ but only in the $e_l$. It is possible to replace this lemma with a variant, where $2m$ excursions (instead of $p$ ones, the $g_q$) are made negative, each $e_l$ being flanked by two of them.

**Lemma 7.** Let $X$ be a process with law absolutely continuous w.r.t. $\pi$, and $E$ a tall excursion of $T \circ X$ with height $H$. There exists an excursion of $X$, with interval $\{s; (T \circ X)(s) = i_{T \circ X} E\}$, and with height $H + |i_{T \circ X} E|$.

**Proof** First, recall a.s., Brownian motion $B$ does not reach its current minimum $I \circ B$ in the interior of a time-interval where $I \circ B$ is constant. (This
is a consequence of \((I \circ B)(s) < 0\) for \(s > 0\) and of the Markov property at the first time that \(B = I \circ B\) after some rational).

Put \(Y = T \circ X\) and call \(F\) the interval \(\{s \geq 0; (I \circ Y)(s) = i_Y E\}\); \(Y\) reaches its current minimum \(I \circ Y\) at both endpoints of \(F\) but not in the interior of \(F\) (see above). Since \(|X| = Y - I \circ Y\) by Lemma 1, we have that \(F\) is the support of some excursion of \(X\). The height of that excursion is

\[
\max(|X_s|; s \geq 0, \quad (I \circ Y)(s) = i_Y E)
= \max(Y_s - (I \circ Y)(s); s \geq 0, (I \circ Y)(s) = i_Y E)
= \max(Y_s; s \geq 0, (I \circ Y)(s) = i_Y E) - i_Y E
= \max(Y_s; s \in E) - i_Y E \quad \text{because } E \text{ is tall}
= H + |i_Y E|.
\]

\[\text{Lemma 8.}\] Let \((0, \overrightarrow{e}, \overrightarrow{j})\) be an orthonormal basis of the plan in which we represent paths. Let \(\tau_b^{a+}\) be the vertical translation of vector \((b - a) \overrightarrow{j}\) and \(\tau_b^{a-}\) the reflection along the horizontal axis of equation \(y = \frac{a + b}{2}\).

Consider \((t, k, p) \in \mathbb{R}_+^* \times \mathbb{N}^2\) such that \(w^k_t = a\) and \(w^{k+p}_t = b\) and denote \(\gamma_t\) the first time posterior to \(t\) when at least one of the iterated Lévy transforms \(w^k, k \leq s \leq k + p - 1,\) vanishes. Then we have:

\[
w^{k+p}_{[t, \gamma_t]} = \begin{cases} 
\tau_b^{a+} \circ w^k_{[t, \gamma_t]} & \text{if } \prod_{i=k}^{k+p-1} w^k_t > 0 \\
\tau_b^{a-} \circ w^{-k}_{[t, \gamma_t]} & \text{else}
\end{cases}
\]

We will denote \(\tau_{k+p}^k(w)\) the plan transformation, which transforms \(w^k_{[t, \gamma_t]}\) in \(w^{k+p}_{[t, \gamma_t]}\).

**Proof** It is an immediate consequence of Tanaka’s Lemma, when \(p = 1\). In general case, we break up the displacement \(\tau\) which transforms \(w^k_{[t, \gamma_t]}\) in \(w^{k+p}_{[t, \gamma_t]}\) under the form \(\tau = \tau_p \circ \tau_{p-1} \circ \cdots \circ \tau_1\) where \(\tau_i\) transforms \(w^{k+i-1}_{[t, \gamma_t]}\) in \(w^{k+i}_{[t, \gamma_t]}\). From the preceding remark, each \(\tau_i\) is a vertical translation or a reflection along an horizontal axis, according to the sign of \(w^{k+i-1}_t\). Then we deduce the claim.
To construct the desired process $\Gamma$, we will proceed by induction on discretized time, and so we will perform, from the level $r$, two types of raisings.
In a first type, the so-called horizontal raisings, at a level when the path vanishes on $[t_d, t_{d+1}]$, we protect the material furnished by the induction hypothesis on $[0, t_d]$, namely $\bar{\Gamma}$. And we prepare the path on $[t_d, t_{d+1}]$ to give it the form it ought to have at this level for being near to $\varphi$ on the interval when $\Gamma$ is near to $\varphi$ on $[0, t_d]$.
So we make positive the significative excursions of the path called here the protected excursions, and insert between them small excursions called
the plug-excursions (see lemma 6). And on $[t_d, t_{d+1}]$, we prepare excursions, the building ones, which we protect, and they will act, one by one, during
a succession of horizontal raisings, to give the path the previewed form (see Lemma 13 and Proposition 14), at the condition the path, after that, will not vanished on $[t_d, t_{d+1}]$.
In a second type, the so called vertical raisings, we give anew to the protected excursions the signs they have before the horizontal raisings. Then we get
up while the path doesn’t vanish on $[t_d, t_{d+1}]$. In fact we must distinguish
the last raising of a succession of horizontal raisings, the so called terminal horizontal raising, when we leave to protect the protected excursions and
give them the good signs.
It is important to know the real level of the path, i.e. the level without the horizontal raisings. Precisely, we define the r.v. inductively:

$$RL_r(w) = r$$

and for all integer $n \leq r$

$$RL_{n-1}(w) = \begin{cases} RL_n(w) & \text{if the step } n - 1 \rightarrow n \text{ corresponds to an horizontal raising} \\ RL_n(w) - 1 & \text{if it corresponds to a vertical raising.} \end{cases}$$

For our needs, we will call map-excursion, or simply excursion, each map $e : \mathbb{R}^+ \to \mathbb{R}$ whose support is a not empty segment and which doesn’t vanish
at any point of the interior of the support. In particular, for $w \in W$ and $t > 0$, we will call excursion straddling $t$, and denote it by $e_t(w)$, the map
so defined:

$$e_t(w) : \mathbb{R}^+ \to \mathbb{R}, \forall u \in \mathbb{R}^+, e_t(w)(u) = \begin{cases} 0 & \text{if } u \in [0, g_t(w)] \cup [d_t(w), +\infty[ \\ w_u & \text{else} \end{cases}$$

We will introduce the map $de_t(w) : \mathbb{R}^+ \to \mathbb{R}$ defined by
∀u ∈ ℜ⁺, de_i(w)(u) = \begin{cases} 
0 & \text{if } u \in [0, t] \cup [R_t(w), +∞[ \\
\ w_u - w_t & \text{else}
\end{cases}

where \( R_t(w) = \sup\{u > t, \forall s \in [0, u], \ w_s \neq w_t\} \)

and we call it a differential excursion of \( w \) whenever its support is not empty, i.e.

\[ \exists \varepsilon > 0, \ \forall u \in (t, t + \varepsilon), \ w_u \neq w_\varepsilon \]

We denote them \( e_t \) and \( de_t \) when there is no ambiguity, and \( e^*_t \) and \( de^*_t \) in the case of excursions of \( w^* \).

Lemma 9. Let \( w \in W \) and \( e \) a negative \( m \)-excursion of \( Tw \), lower than all preceding it. Let \( \gamma \) be its beginning and \( \delta \) its end. We set:

\[ \gamma_1 = \arg \min_{[0, \gamma]} Tw, \ \gamma_2 = \inf \{t \in \text{supp}(e); e(t) = Tw_{\gamma_1}\}, \ \gamma_3 = \arg \min_{[\gamma, \delta]} e \]

Then:

\[ \begin{cases} 
de_{\gamma_1} \text{ coincides with an excursion of } |w|, \text{ and its support is } [\gamma_1, \gamma_2] \\
de_{\gamma_3} \text{ coincides with an excursion of } |w|, \text{ which begins at } \gamma_3 \text{ and whose support contains } [\gamma_3, \delta]
\end{cases} \]

Furthermore, \( \forall u \in [\gamma_2, \gamma_3], de_u \) coincides with an excursion of \( |w| \), if, and only if:

\[ \begin{cases} 
de_u \text{ is a positive excursion} \\
e(u) = \inf\{e(t), t \in [\gamma, u]\}
\end{cases} \]

It is the case in particular when \( de_u \) is the first positive excursion of the form \( de_v, v \in [\gamma_2, \gamma_3] \) to overflow a given value.

Proof

From Tanaka’s formula:

\[ |w_t| = Tw_t + \sup\{-Tw_u, u \in [0, t]\} \]

Therefore,

\[ |w_{\gamma_1}| = Tw_{\gamma_1} - Tw_{\gamma_1} = 0, \]

while, for all \( t > \gamma_1 \), sufficiently small:

\[ Tw_t > Tw_{\gamma_1}. \]

So, \( de_{\gamma_1} \) is a positive excursion of \( |w| \) which ends at \( \gamma_2 \).

In the same way, \( Tw_t > Tw_{\gamma_3} \), for all \( t \in [\gamma_3, \delta] \), therefore \( de_{\gamma_3} \) is an excursion

14
of $|w|$ beginning at $\gamma_3$ whose support contains $[\gamma_3, \delta]$. Let $e'$ be an excursion of $w$ with support included in $[\gamma_2, \gamma_3]$. Its beginning $u$, and its end $v$ verify:

$$u = \arg \min_{[0,v]} Tw \quad \text{and} \quad v = \arg \min_{[0,v]} Tw.$$ 

So we deduce: $de_u = |e'|$. Reciprocally, let $u \in [\gamma_2, \gamma_3]$ such that $de_u$ is a positive excursion and $u = \arg \min_{[0,u]} Tw$.

Then, $u = \arg \min_{[0,v]} Tw$, where $v$ is the end of $de_u$, because $de_u$ is positive. Thus, $w_u = w_v = 0$, and for all $t \in [u,v[$, $w_t \neq 0$. Consequently, $de_u$ is an excursion of $|w|$. Let $h > 0$ be such that there exists $u \in [\gamma_2, \gamma_3]$ verifying $de_u$ is the first positive excursion of the form $de_u$, $v \in [\gamma_2, \gamma_3]$, whose height overflows $h$. Then, for all $v < u$, the support of $de_u$ can’t contain this of $de_u$ without denying the minimality of $u$.

As an immediate consequence, we observe:

**Corollary 2.** The excursions of $w$ coincide with the positive differential excursions of $Tw$, beginning at $\arg \min_{[0,t]}(Tw)$ for all $t \in [0, +\infty[$.
2 Density of orbits

In this paragraph, we want the raised path to approach the map \( \varphi \) uniformly on \([0, T]\). Precisely:

Whatever \( \varepsilon \) strictly positive, and \( \varphi \in W_{[0,T]} \), there exists \( \Gamma \) a \( B \)-raised Brownian motion such that:

\[
P \left( \| \Gamma_{[0,T]} - \varphi_{[0,T]} \|_{\infty} < \varepsilon \right) > 1 - \varepsilon
\]

We consider a modulus of uniform continuity \( \alpha_0 \) associated to \( \left( \frac{\varepsilon}{4}, \varphi, [0, T]\right) \) and a real number \( \alpha_1 \) such that \( P(A_{0\varepsilon}) > 1 - \frac{\varepsilon}{2} \) where

\[
A_{0\varepsilon} = \left[ \sup\{|B_t - B_u|, (t, u) \in [0, T]^2 \text{ and } |t - u| < \alpha_1\} < \frac{\varepsilon}{2} \right],
\]

then we set \( \alpha := \min(\alpha_0, \alpha_1) \), \( d_0 := \left[ \frac{\varepsilon}{2\alpha} \right] + 1 \), and for all \( d \in \mathbb{N} \), \( t_d = (d\alpha) \wedge T \).

We set again, for all integer \( d \in [1, ..., d_0] \),

\[
A_d := \left[ \sup\{|B_t - B_u|, (t, u) \in [t_d, T]^2, |t - u| < \alpha\} < \frac{\varepsilon}{2} \right].
\]

Our aim is to show, by induction on \( d \), the following property \( P_d : \) "For all \( \varepsilon > 0 \), there exists an integer \( r_d \) and \( \Gamma \) a \( B \)-raised Brownian motion of index \( r_d \) such that:

\[
P \left( \| \Gamma_{[0,t_{r_d}]} - \varphi_{[0,t_{r_d}]} \|_{\infty} < \varepsilon \right) \cap \| \Gamma_{t_d} - \varphi(t_d) \| < \varepsilon_1 \cap A_d \right) > 1 - \varepsilon \left( 1 + \frac{d}{d_0} \right) \]

Notice that \( P_0 \) immediately yields from the choice of \( \varphi \) which vanishes at 0. We suppose now \( P_d \) true. We are going to apply this hypothesis to the Brownian motion \( B^{s_0} \), for an integer \( s_0 \) which, as the real number \( \varepsilon_1 \), will be later specified.

As \( A_d \subset \left[ \sup\{|B_t - B_u|, (t, u) \in [t_d, t_{d+1}]^2 \} < \frac{\varepsilon}{2} \right] \cap A_d^{d+1} \), and from the independence of the increments of Brownian motion, we can deduce the existence of a disjointed sum \( \tilde{\Gamma} \) of \( B^{s_0} \)-raised Brownian motions of index \( r_d \) such that:

\[
P(A_0) > 1 - \varepsilon \left( 1 + \frac{d}{d_0} \right),
\]

where

\[
A_0 := \left[ \| \tilde{\Gamma}_{[0,t_{r_d}]} - \varphi_{[0,t_{r_d}]} \|_{\infty} < \frac{\varepsilon}{2} \right] \cap \| \tilde{\Gamma}_{t_d} - \varphi(t_d) \| < \varepsilon_1 \]

... \( \cap \sup\{|B_{t^{s_0}+r_d} - B_u^{s_0+r_d}|, (t, u) \in [t_d, t_{d+1}]^2 \} < \frac{\varepsilon}{2} \right] \cap A_e^{d+1}
\]
(It suffices to apply $P_d$ with $\frac{\varepsilon}{4}$ instead of $\varepsilon$).

We will denote: $\forall i \in \mathbb{N}$, $\tilde{w}^i = \tilde{w}^i$. By definition, $\forall i > r_d$, $\tilde{w}^i = w^{s_0 + i}$.

From the theorem of density of zeroes ([M]), there exists a.s. an integer $\ell$ such that $\tilde{w}^{\ell}$ vanishes at least one time on $[t_d, t_{d+1}]$.

Let $L(w)$ be the smallest of these integers $\ell$. $L$ is a r.v. almost surely finite.

Then there exists an integer $\ell_0$ which we will choose $> r_d$ such that:

$$P(A_1^\varepsilon) > 1 - \varepsilon \left(1 + \frac{d}{d_0}\right) - \frac{\varepsilon}{2d_0} \quad \text{où} \quad A_1^\varepsilon := A_0^\varepsilon \cap [L \leq \ell_0].$$

We set $r = s_0 + \max(r_d, l_0)$.

**Definition 3.** The protecting tree of $\Gamma$.

Let $\mathcal{N}$ be a set of excursions of $w|_{[0, d(w)]}$, $w \in \mathcal{W}$, and $\varepsilon > 0$. We denote by $T_w^{t, \varepsilon}(\mathcal{N})$ the set of excursions of $T_w|_{[0, d(T_w)]}$ so defined: $e' \in T_w^{t, \varepsilon}(\mathcal{N})$ iff $e'$ is an excursion of $T_w|_{[0, d(T_w)]}$ which appears in the differential excursions $dE$ of $T_w$ corresponding to an excursion $E \in \mathcal{N}$, and $h(e') > \frac{\varepsilon}{4}$ (we call them excursions of the first type) or the support of $e'$ contains $\arg \max$ of the differential excursion $dE$, we call them excursions of the second type, and all the excursions $e''$ of $T_w$ of height belonging to $[h(e'), h(e'_-)]$, $e'_-$ being the preceding excursion of $T_w$ of height $> \frac{\varepsilon}{4}$, with $e'_- < e'' < e'$, we call these excursions $e''$ the third type excursions.

**Lemma 10.** When $\mathcal{N}$ is a finite set, so is $T_w^{t, \varepsilon}(\mathcal{N})$.

**Proof** We remark firstly that the number of distinct differential excursions of $T_w$ corresponding to the elements of $\mathcal{N}$ is finite, equal to the cardinal of $\mathcal{N}$. The number of excursions of the first type is finite because their height is greater than $\frac{\varepsilon}{4}$. The number of excursions of the second type is finite following the first remark. And for each excursion of the second type, the number of excursions of the third type is finite too.

Then we call protecting tree of $\Gamma$, the tree constituted by:

- at the 0-generation: the elements of $\tilde{\mathcal{N}}^0$, the set of $d_t(\tilde{w}^0)$-excursions of height $> \varepsilon$.

- and, for all $n \in \mathbb{N}$, if we denote by $\tilde{\mathcal{N}}^n$, the set of protected excursions of $\tilde{w}^n$ whose elements, given in chronological order, constitute the $n^{th}$
generation of the tree, then at the \((n + 1)^{th}\) generation, the elements of \(\tilde{N}^{n+1} := T_{\tilde{w}^n}^{t^*} (\tilde{N}^n)\). As we have ordered each \(\tilde{N}^n\), which is now a finite sequence of excursions of \(\tilde{w}^n\), we can consider \(\tilde{\Sigma}^n\) the finite sequence of their signs. And our next task is to define \(N^n\) the sequence of protected \(t_\infty\)-excursions of \(\Gamma^n\) and \(\Sigma^n\) the associated sequence of their signs. We have defined the \(\tilde{N}^n\)'s by getting down in the iterations. We will define the \(\tilde{N}^m\)'s by getting up from level \(r\). We put \(N^r(\omega) = N^{r-s_0}(\omega)\), and \(\Sigma^r(\omega) = \Sigma^{r-s_0}(\omega)\).

If \(\Gamma^{n+1} \rightarrow \Gamma^n\) is an horizontal raising, then \(N^{0,n+1}\) is constituted by the family of the excursions of \(\Gamma^n\) whose absolute values have the same \(\arg \max\) as the excursions of \(N^{0,n+2}\). Then we proceed as in lemma 6, considering the elements of \(N^{0,n+1}\) as the \(e_i\), \(1 \leq i \leq m\). We have now to define the r.v. \(\eta\): let \(\eta_i\) be the minimal distance between the heights of distinct protected excursions of \(\tilde{w}^n\) for \(i \in \{0, \ldots, r-s_0\}\) and \(\eta_m = r-s_0\).

If \(\Gamma^{n+1} \rightarrow \Gamma^n\) is a vertical raising, \(N^{r+1}\) is constituted by the family of the excursions of \(\Gamma^n\) corresponding to the positive differential excursions of \(\Gamma^{n+1}\) whose support encounters at least the support of an element of \(N^{0,n+2}\) and beginning at an \(\arg \min\) of \(\Gamma^{n+1}\). In these two cases, to specify \(N^{n+1}\), we need the following lemma. Let us call \(\arg \max\) of an excursion the \(\arg \max\) (resp. \(\arg \min\)) of this excursion if it is positive (resp. negative).

**Lemma 11.** If for all \(i\) from level \(r\) to \(n\) (with \(r \geq n\)) the elements of \(N^{0,n+1}\) and \(\tilde{N}^{RL(i)-s_0}\) have the same \(\arg \max\), which implies \(|N^{0,n+1}| = |\tilde{N}^{RL(i)-s_0}|\), and the same signs, then the elements of \(N^{0,n+1}\) and \(\tilde{N}^{RL(n-1)-s_0}\) have the same \(\arg \max\), hence these sets have the same cardinality, and the same hierarchy, i.e. the order of the heights between the respective excursions of each set is the same. So we put \(\Sigma^{0,n+1} = \tilde{\Sigma}^{RL(n-1)-s_0}\).

**Proof** The distinction between \(\Gamma\) and \(\tilde{\Gamma}\) is due to the introduction of horizontal raises. If \(\Gamma^{n+1} \rightarrow \Gamma^n\) is an horizontal raising, each protected excursion gains in height the height of a plug excursion, and its support enlarges. So, during such a raising, the "error" between \(\Gamma\) and \(\tilde{\Gamma}\) increased at the height of a plug excursion. For the time, in this lemma, the "error" means...
the maximal distance between the heights of corresponding excursions. If, on the other side, $\Gamma^{n+1} \rightarrow \Gamma^n$ is a vertical raising, a protected excursion of $\Gamma^n$ is constituted by at most two protected excursions of $\Gamma^{n+1}$. So during such a raise, the error between $\Gamma$ and $\Gamma'$ doubles. And it is easy, by means of our choice of the heights of the plug excursions, to show that this error is always majorized by $\varepsilon \wedge \eta$. Hence the lemma follows immediately.

Now we can consider (see Proposition 2) that $\Gamma_{[0,t_d]}$ is correctly defined : for once $RL_w(n) = s_0$, we end the raises, if necessary, by horizontal ones : protecting all the material acquainted. But is $\Gamma$ near from $\Gamma'$? To answer this question, we have to consider the error between $\Gamma$ and $\Gamma'$ now, as being $\|\Gamma_{[0,t_d]} - \Gamma'_{[0,t_d]}\|_{\infty}$.

We have just built $\Gamma_{[0,t_d]}$. We have now to control : $\|\Gamma^N_{[0,t_d]} - \Gamma^0_{[0,t_d]}\|_{\infty}$, where $N = \sup \{n \in \{0, \ldots, r\} / RL(n) = s_0 = 0\}$ (with $N = -\infty$ if the set is empty). $N$ is a r.v.

**Lemma 12.** $\|\Gamma^N_{[0,t_d]} - \Gamma^0_{[0,t_d]}\|_{\infty} \leq 2\varepsilon$, on the event $[N \geq 0]$.

**Proof** Let us first remark, from the preceding lemma, that, on the event $[N \geq 0]$, we have protected excursions with the same argext, the same signs, and heights near at $\varepsilon$. The supports of the protected excursions of $\Gamma^N$ containing the supports of the corresponding protected excursions of $\Gamma^0$. Furthermore, on the difference of their supports, $\Gamma^N$ and $\Gamma^0$ differ from at most $2\varepsilon$, and likely outside the union of their supports.

The purpose of the following lemma is to prepare, at level $s$, when the iterated Brownian motion vanishes on $[t_d, t_{d+1}]$, the excursions which will allow the correctly raised path to approach $\varphi$ at level 0 on $[t_d, t_{d+1}]$.

**Lemma 13.** Full planing.

Let $w$ belong to $W$, and $t, t', \varepsilon' \in \mathbb{R}_+^*$ be such that $t < t'$. We suppose there is no interval in which $w$ is constant, and $w$ vanishes in $(t, t')$. The following r.v. are functionals of $|w|$ :

- $t_0(w) = \inf\{s > d_t ; |w_s| \geq \varepsilon'\} \wedge t'$, with $\inf\emptyset = +\infty$.

- $\forall n \in \mathbb{N}$, while $t_n < t'$, we set :

  $t_{n+1} := \begin{cases} 
  \inf\{u \in [t_n ; \arg\max |de_{t_n}| ; h(de_u) > \varepsilon' \text{ and } sgn(de_u) = -sgn(de_{t_n})\} \\
  \text{if this set is not empty,} \\
  \text{else :} \\
  \arg\max |de_{t_n}| \wedge t'
  \end{cases}$
The sequence \((t_n)_{n \in \mathbb{N}}\) is strictly increasing and finite. Let \(1 + K(w)\) be its cardinality.

**Proof** By construction, the sequence \((t_n)\) is strictly increasing and lower than \(t'\). Suppose the number of its terms is infinite. In this case, it would admit a limit \(t_\ast \leq t'\), and the oscillation of \(w\) at \(t_\ast\) would be infinite, so contradicting the continuity of \(w\). Then \((t_n)_n\) is finite.

The measurability and the finiteness of \(K\) are immediate.

Let us remark that this Lemma gives us the possibility of planning the path after \(d_i\) in \(K\) raises.

For, during the first raise, we put negative the excursion beginning at \(t_0(w)\) and positive all the other excursions in \((t_0(w), t')\) of height greater than \(\varepsilon'\).

Then during the second raise, we put negative the excursion whose support contains this of \(de_{t_1}\), and so on. At the end of such \(K\) raises, the path on \([t_0, t']\) has an absolute value which doesn’t exceed \(\varepsilon' + K\varepsilon''\), and \(\varepsilon'\) on the excursion straddling \(t'\).

So we are going now to analyze its behavior on \((t_d, t_{d+1})\). Let us denote \(\gamma_{t_d}\) the first time after \(t_d\) at which one of the \(\Gamma_\sigma\), \(0 \leq \sigma \leq s_0 + t_0\), vanishes on \((t_d, t_{d+1})\), and \(\sigma_0\) the corresponding level.

**Proposition 4.** There exists a \(\sigma(\Gamma_0^{\sigma_0+1})\)-measurable, \(\mathbb{N}\)-valued r.v., \(K_{\sigma_0}'\) such that there exists \(K_{\sigma_0}' - 1\) r.v. \(P_1, \ldots, P_{K_{\sigma_0}' - 1}\) themselves with values in \(\mathbb{N}\) and \(\sigma(\Gamma_0^{\sigma_0+1})\)-measurable, such that :

\(i\) the \(K_{\sigma_0}' - 1\) excursion intervals \(e_{P_1}(\Gamma_0^{\sigma_0}), \ldots, e_{P_{K_{\sigma_0}' - 1}}(\Gamma_0^{\sigma_0})\) are disjoint and included in \((d_{t_d}(\Gamma_0^{\sigma_0}), t_0(\Gamma_0^{\sigma_0}))\)

\(ii\) the heights \(H_1, \ldots, H_{K_{\sigma_0}' - 1}\) of these \(K' - 1\) excursions of \(\Gamma_0^{\sigma_0}\) satisfy on \([\sigma_0 \geq 0]\) :

\[
\left| \tau_{RL_{\sigma_0} - s_0}(\tilde{w})(\varphi(t_{d+1})) \right| - \varepsilon' < H_1 + \ldots + H_{K_{\sigma_0}' - 1} < \left| \tau_{RL_{\sigma_0} - s_0}(\tilde{w})(\varphi(t_{d+1})) \right| + \varepsilon'.
\]

**Proof** Noticing that the process :

\[
X = \sum_{n \in \mathbb{N}} \Gamma^n I_{[\sigma_0 = n]}
\]

is absolutely continuous w.r.t. \(\pi\), the proposition is an immediate consequence of lemma 5.
Often in the sequel, we will denote $K'_{\sigma_0}$ simply by $K'$, if there is no ambiguity.

Set:

\[ \sigma'_0 = \sigma_0 - (K(\Gamma^{\sigma}) + K'_{\sigma_0}) \]

**Proposition 5.** For all $(n, \omega)$ such that $\sigma_0(\omega) \leq n < \sigma_0(\omega) - K'_{\sigma_0}(\omega)$, $N^n(\omega)$ and $\Sigma^n(\omega)$ can be chosen so that:

(i) \[ 0 \leq \Gamma^{\sigma_0-K}_{t_d+1} < \varepsilon' \text{ and } \|\Gamma^{RL(\sigma_0-1) - s_0}_{[0,t_d]} - \Gamma^{\sigma_0}_{[0,t_d]}\|_{\infty} < K\varepsilon''. \]

(ii) \[-(I \circ \Gamma^{\sigma_0})(t_{d+1}) = H_{K'_{\sigma_0}-1}.\]

(iii) $\Gamma^{\sigma_0}$ has $K' - 2$ tall excursions included in $(t_d, t_{d+1})$: $E_1 < E_2 < \ldots < E_{K'_{\sigma_0}-2}$ verifying $|i_{\Gamma^{\sigma_0}} E_1| < |i_{\Gamma^{\sigma_0}} E_2| < \ldots < |i_{\Gamma^{\sigma_0}} E_{K'_{\sigma_0}-2}|$.

(iv) $H_{n+1} + \ldots + H_{K'_{\sigma_0}-1} \leq \Gamma^{\sigma_0-K-n}_{t_d+1} < H_{n+1} + \ldots + H_{K'_{\sigma_0}} + \varepsilon' + nK'\varepsilon''.$

(v) $H_{K'_{\sigma_0}-n} < -(I \circ \Gamma^{\sigma_0-K-n})(t_{d+1}) < H_{K'_{\sigma_0}-n} + K'\varepsilon''.$

(vi) $\Gamma^{\sigma_0-K_{\sigma_0}-n}$ has $K'_{\sigma_0} - n - 2$ tall excursions included in $(t_d, t_{d+1})E^n_1 < \ldots < E^n_{K'_{\sigma_0}-n-2}$ such that: $|i_{\Gamma^{\sigma_0-K_{\sigma_0}-n}} E_1| < \ldots < |i_{\Gamma^{\sigma_0-K_{\sigma_0}-n}} E_{K'_{\sigma_0}-n-2}| < \varepsilon''$, and whose heights $H^n_1, \ldots, H^n_{K'_{\sigma_0}-n-2}$ satisfy:

\[ H_l \leq H^n_l < H_l + n\varepsilon'' \text{ for } n + 1 \leq l \leq K'_{\sigma_0} - 1. \]

In our pursuit of the procedure, we can state:

**Proposition 6.** It is possible to choose $N^n(\omega)$ and $\Sigma^n(\omega)$, for all $(n, \omega)$ such that $n = \sigma'_0$, in order to have:

\[ \left| \Gamma^{\sigma'_0}_{t_{d+1}} - \tau^{0}_{RL(\sigma'_0 - s_0)}(\varphi(t_{d+1})) \right| < \varepsilon' + \frac{1}{2}(K'_{\sigma_0} - 1)(K'_{\sigma_0} - 2)\varepsilon''. \]

**Proof** We notice that the building excursions which appear in Proposition 5, the $\epsilon_{RL}(\Gamma^{\sigma_0+K'_{\sigma_0}})$’s, are successively protected. Once protected, each of them receives a small excursion of height lower than $\varepsilon''$ at each raise. So we deduce the result.
Proposition 7. It is possible to define $\mathcal{N}^n(\omega)$, $\Sigma^n(\omega)$ and $RL_n(\omega)$ inductively on the event $[n \geq \sigma'_0]$ if $\Gamma^n(\omega)$ doesn’t vanish in $(t_d, t_{d+1})$ and $RL_n(\omega) > s_0$, in such a way that:

(i) $\left\| \Gamma^n_{[0(B^\sigma_0), t_{d+1}]} - \Gamma^n_{t_{d+1}} \right\|_\infty < \varepsilon' + K(B^\sigma_0)\varepsilon''$.

(ii) $|\Gamma^n_{t_{d+1}} - \tau^0_{RL_n-s_0}(\varphi(t_{d+1}))| < \varepsilon' + \frac{1}{2}(K'_{\sigma_0} - 1)(K'_{\sigma_0} - 2)\varepsilon'' + 2^n - (\sigma_0 - \sigma'_0)\varepsilon''$.

Proof We first recall that when we know $\Gamma^{n+1}(\omega)$, we know also whether $\Gamma^n$ vanishes in $(t_d, t_{d+1})$. If it isn’t the case, we put :

$$RL_n(\omega) = RL_{n+1}(\omega) - 1,$$

and define $\mathcal{N}^n(\omega)$ and $\Sigma^n(\omega)$ as we do in previous propositions; but this time the counting of "errors" is radically different. It can happen between 0 and $t_d$ that an excursion which was protected before become negative and, in the following raise, is going to add to another protected excursion. So, at each vertical raise, the "errors" are double of those of the preceding raise.

In the same manner the excursion straddling $t_{d+1}$ receives an excursion with beginning in $[0, t_d]$. So, to the errors soon acquainted at level $J'_0$ we must add the error between 0 and $t_d$ of the preceding level which entails (ii).

For (i) : here the raises which are involved, are the planing one’s, i.e. the $K(\Gamma^\sigma_n)$ first raises. At most, at each instant of the interval $[0, B^{J'_0-1}, t_{d+1}]$, the path $\Gamma^n$ has received $K(\Gamma^\sigma_0)$ small excursions. Then, this part of the path is just successively translated, which entails (i).

Then we define $\sigma_n$, $n \geq 0$, $hz_n$ and $vt_n$ in the following manner :

$$\forall n \in \mathbb{N}, \sigma_{n+1} = \sup(\sup\{p > \sigma'_n, \Gamma^p vanishes in (t_d, t_{d+1})\}, 0)$$

$hz_n$ (resp. $vt_n$) is the number of horizontal (resp. vertical) raisings occurring between levels $r$ and $n$. As before, $S = \sup\{n \leq r; RL_n = s_0\}$.

Proposition 8. (i) For all $n \in \mathbb{N}$, $\sigma_n$, $hz_n$, $vt_n$ are r.v.

(ii) It is possible to define $\mathcal{N}^n$ and $\Sigma^n$ on the event $[\sigma_k \geq n \geq \sigma_k]$ in such a manner that :
\[(a) \quad \left\| \Gamma^n_{[0, (B^{n^2-1})t_d+1]} - \Gamma_{t_d+1}^n \right\|_\infty < \varepsilon' + K(\Gamma^\alpha)\varepsilon''
\]
\[(b) \quad \left| \Gamma^n_{t_d+1} - \frac{\tau_{R - 1}}{n^2}((\varphi(t_{d+1})) \right| < \varepsilon' + \frac{1}{2}(K_{\sigma_k} - 1)(K_{\sigma_k} - 2)\varepsilon'' + hz_\varepsilon 2^{nt_n}
\]

**Proof** It is the same as in the previous proposition. For (a) we notice that, after the intervention of the planing excursions, this part of the path is merely translated, without being affected by any other modification.

**Proposition 9.** (i) \( S \) is a r.v. such that \( S - s_0 \) doesn't depend upon \( s_0 \) and \( \varepsilon'' \), and we can choose \( s_0 \) large enough for \( P(A_2^s) > 1 - \varepsilon(1 + \frac{d}{s_0}) - \frac{\varepsilon}{s_0} \), where \( A_2^s := A_2^s \cap \{ S \geq 0 \} \).

(ii) Let \( (\Gamma^n) \) be the sequence associated to the \( N^n \) and \( \Sigma^n \). It satisfies on \( A_2^s \):

\[
\left\| \Gamma^{S}_{[0, t_d]} - \tilde{\Gamma}^0_{[0, t_d]} \right\| \infty < 2\varepsilon
\]
\[
\left\| \Gamma^{S}_{[t_0, (B^{n^2})t_{d+1}]} - \Gamma^{S}_{t_{d+1}} \right\| \infty < \varepsilon' + K(B^{\alpha^2})\varepsilon'', \quad \text{where } n_S = \sup \{ n \leq r/\sigma_n \leq S \}
\]
\[
\left| \Gamma^{S}_{t_{d+1}} - \varphi(t_{d+1}) \right| < 2\beta + \varepsilon' + \frac{1}{2}(hz_\varepsilon - 1)(hz_\varepsilon - 2)\varepsilon'' 2^{l_0} + \left( \varepsilon'' h z_{s_0 - S} \varepsilon'' \right).
\]

**Proof** For (i), see Lemma 12. Then (ii) follows immediately from preceding Propositions.

Then \( \Gamma \) so defined is a \( B \)-raised Brownian motion.

So, let us choose : \( \varepsilon' = \frac{\varepsilon}{16} \) and \( \varepsilon'' = \frac{\varepsilon}{16(\frac{1}{2})^{(s_0 - 1)(s_0 - 2) + 2s_0 s_0}} \).

From the independence of the r.v. \( S - s_0 \), upon \( s_0 \) and \( \varepsilon'' \), these choices don’t create any vicious circle, and we can claim:

**Proposition 10.** For all \( \varepsilon > 0 \), there exists a \( B \)-raised Brownian motions verifying on the event \( A_2^s \):

\[
(18) \quad \left\| \Gamma^0_{[0, t_d]} - \varphi_{[0, t_d]} \right\| \infty < \varepsilon
\]
\[
(19) \quad \left\| \Gamma^0_{[t_0, (B^{n^2})t_{d+1}]} - \varphi_{[t_0, (B^{n^2})t_{d+1}]} \right\| \infty < \frac{\varepsilon}{8} + \frac{\varepsilon}{4}
\]
\[
(20) \quad \left| \Gamma^0_{t_{d+1}} - \varphi(t_{d+1}) \right| < \frac{\varepsilon}{4}.
\]
Proof  We deduce immediately these increases from Proposition 25 since 
$S \leq s_0$, $h z J_0 - S \leq s_0$, $K(\Gamma^J z_0) \leq s_0$.

At this point, the last task to achieve is to control $\Gamma^0$ between times $t_0(B^{d_0})$ and $t_{d+1}$.

So we are going now to analyze more in details its behavior on $(t_d, t_{d+1})$. 
Let us denote $\gamma_{t_d}$ the first time after $t_d$ at which one of the $\Gamma^\sigma$, $0 \leq \sigma \leq s_0 + l_0$, 
vanesishes on $(t_d, t_{d+1})$, and $\sigma_0$ the corresponding level. 
Let us introduce the rectangle Rect$_{\sigma_0}$ defined by the four straight lines with 
equations:
\begin{align*}
  x = t_d, x = t_{d+1}, y = \inf \tau^0_{(RL, - \sigma_0)}(\varphi) ||_{[t_d, t_{d+1}]} \quad \text{and} \\
  y = \sup \tau^0_{(RL, - \sigma_0)}(\varphi) ||_{[t_d, t_{d+1}]}
\end{align*}
Rect$_{\sigma_0}$ contains by definition the path of $\tau^0_{(RL, - \sigma_0)}(\varphi) ||_{[t_d, t_{d+1}]}$ and, from the 
choice of $\alpha_0$, its height is lower than $\varepsilon/4$.

Now consider the path of $\Gamma(w)^{\sigma_0}||_{[t_d, t_{d+1}]}$, it takes one of the two forms given in the 
appendix.

In the two cases by hypothesis, the total variation of $w^{\sigma_0 + \tau_d}$ on $[t_d, t_{d+1}]$ is 
lower than $\varepsilon/2$. So, by lemma 5, and the definition of $\gamma_{t_d}$, it is greater or equal 
to that of $\Gamma(w)^{\sigma_0}$ on $[t_d, \gamma_{t_d}]$. Consequently the path $w^{\sigma_1}$ can move again 
from Rect$_{\sigma_0}$ but at most from $\frac{\varepsilon}{4} + \frac{\varepsilon}{2}$ on the same interval.

And rapidly, it is bound to join $\varphi$ in Rect$_{\sigma_0}$ by the building excursions, the 
flat part remaining flat.

Therefore, the rectangle RR$_{\sigma_0}$, with the same center and vertical straight lines 
bordering it, and height that of Rect$_{\sigma_0} + \frac{3\varepsilon}{4}$, contains the path $w^{\sigma_1||_{[t_d, t_{d+1}]}$. 
During the following raises, the rectangle Rect$_{\sigma_0}$, according to lemma 5, 
moves by isometry. We call $R_{\sigma}$ its new positions, and likewise RR$_{\sigma}$ that of 
RR$_{\sigma_0}$.

We can easily check that, for all $\sigma < \sigma_1$ corresponding to a vertical raise, the path 
$w^{\sigma||_{[t_d, t_{d+1}]}$ is contained in RR$_{\sigma}$.

Finally, for $w \in A^*_2$ at level 0 we have the desired property :
\[
\|\Gamma^0||_{[t_d, t_{d+1}]} - \varphi||_{[t_d, t_{d+1}]}\|_\infty < \varepsilon
\]

So we have proved the following :
Proposition 11. For all $\varepsilon > 0$, there exists a disjointed sum of $B$-raised Brownian motions such that: on $A_3^\varepsilon$,

\begin{align}
(21) \quad &\|\Gamma^0|_{[t_d,t_{d+1}]} - \varphi|_{[t_d,t_{d+1}]}\| < \varepsilon \\
(22) \quad &\left|\Gamma^0_{t_{d+1}} - \varphi(t_{d+1})\right| < \frac{\varepsilon}{4}.
\end{align}

Thus we establish that $P_{d+1}$ is true. So, by induction, $P_d$ is true for all $d \leq d_0$, and we can claim:

Proposition 12. For all $\varepsilon > 0$, there exists a disjointed sum of $B$-raised Brownian motions such that:

$$P \left( [\|\Gamma^0_{[0,T]} - \varphi_{[0,T]}\|_\infty < \varepsilon] \cap [\|\Gamma_T - \varphi(T)\| < \frac{\varepsilon}{4}] \right) > 1 - 2\varepsilon.$$  

Then we can apply Proposition 1 to $G = [\|w|_{[0,T]} - \varphi_{[0,T]}\|_\infty > \varepsilon]$. So,

$$P \left( \forall n \geq 0, \|B^n|_{[0,T]} - \varphi_{[0,T]}\|_\infty > \varepsilon \right) < 2\varepsilon$$

We deduce immediately:

$$P \left( \forall n \geq 0, \|B^n|_{[0,T]} - \varphi_{[0,T]}\|_\infty > \varepsilon \right) = 0.$$  

But this property is true again when we replace 1 by $a$, for all $a > 0$ : This means:

Theorem 1.  
For almost every $\omega \in \Omega$, the orbit of $B(\omega)$:

$$orb(B(\omega)) = \{B^n(\omega); n \in \mathbb{N}\}$$

is dense in $W$, equipped with the topology of uniform convergence on compact sets.

Let us notice that if, in place of restrain ourselves with the open sets $B$, we have shown:

$\forall B$ closed set in $W$,

$$P(B) > 0 \Rightarrow P(\text{orb}(w) \cap B \neq \emptyset) = 1$$

Then every set $A$ $T$-invariant, measurable and not negligible, would contain the event $[\text{orb}(w) \cap B \neq \emptyset]$ and so, would be almost sure. Therefore, $T$ would
be ergodic.
To end, we are going to claim in an equivalent way, following thus an interesting suggestion of J.P Thouvenot :
$$\forall (\varphi, \varepsilon) \in W_{[0,1]} \times \mathbb{R}_+^\ast,$$
the reverse martingale $P(w \in B(\varphi, \varepsilon)|W_n)$ admits a regular conditional version $P(w \in B(\varphi, \varepsilon)|w^n)$, and we have :

**Theorem 2.**

$$P \text{ a.s.}, \lim_{n \to \infty} P(w \in B(\varphi, \varepsilon)|w^n) > 0$$

**Proof of theorem 3.**
Suppose the contrary, and let :
$$A := \left[ w \in W, \lim_{n \to \infty} P(w \in B(\varphi, \varepsilon)|w^n) = 0 \right]$$
As $P(w \in B(\varphi, \varepsilon)|w^n) = P(w \in B(\varphi, \varepsilon)|w^{n+1})$, because $T$ is measure-preserving. So we have :
$$w \in A \iff Tw \in A$$
So $A$ is $T$-invariant. Consequently :
$$E(1_A P(w \in B(\varphi, \varepsilon)|w^n)) = P(A \cap [w \in B(\varphi, \varepsilon)]) = P(A \cap [w^n \in B(\varphi, \varepsilon)])$$
But by hypothesis :
$$\lim_{n \to \infty} E(1_A P(w \in B(\varphi, \varepsilon)|w^n)) = 0$$
Therefore,
$$P(A \cap [\text{orb}(w) \cap B(\varphi, \varepsilon) \neq \emptyset]) = 0$$
which, from theorem 1, entails that $P(A) = 0$

Finally, let us remark that, if we could show :
$$\lim_{n \to \infty} P\left( \left[ w \in B(\varphi, \varepsilon) \right] |w^n \right) = P\left( \left[ w \in B(\varphi, \varepsilon) \right] \right),$$
Then, not only $T$ would be ergodic but exact which means :
$$W_\infty := \bigcap_{n \in \mathbb{N}} W_n$$ would be trivial.
