HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# INFINITELY DIVISIBLE DISTRIBUTIONS FOR RECTANGULAR FREE CONVOLUTION：CLASSIFICATION AND MATRICIAL INTERPRETATION 

FLORENT BENAYCH－GEORGES

#### Abstract

In a previous paper（B－G1），we defined the rectangular free convolution $\boxplus_{\lambda}$ ．Here， we investigate the related notion of infinite divisiblity，which happens to be closely related the classical infinite divisibility：there exists a bijection between the set of classical symmetric in－ finitely divisible distributions and the set of $\boxplus_{\lambda}$－infinitely divisible distributions，which preserves limit theorems．We give an interpretation of this correspondance in term of random matrices： we construct distributions on sets of complex rectangular matrices which give rise to random matrices with singular laws going from the symmetric classical infinitely divisible distributions to their $\boxplus_{\lambda}$－infinitely divisible correspondants when the dimensions go from one to infinity in a ratio $\lambda$ ．

## Introduction

In a previous paper（ B－G1］），we modeled the asymptotic behaviour of rectangular random matrices with freeness with amalgamation．Therefore we defined，for each $\lambda \in[0,1]$ ，the rect－ angular free convolution with ratio $\lambda$ ，denoted by $⿴ 囗 十 八 \lambda$ ．It is a binary operation on the set of symmetric probability measures on the real line defined in the following way．Let us call the singular law of a matrix $M$ the uniform law on its singular values，i．e．on the spectrum of its

[^0]absolute value $|M|=\left(M M^{*}\right)^{1 / 2}$. Consider $\mu, \nu$ symmetric probability measures on the real line, consider two sequences $q_{1}(n), q_{2}(n)$ of integers tending to $+\infty$ such that
$$
\frac{q_{1}(n)}{q_{2}(n)} \underset{n \rightarrow \infty}{\longrightarrow} \lambda
$$
and consider, for each $n, M(n), N(n)$ independent $q_{1}(n) \times q_{2}(n)$ random matrices, one of them being biunitarily invariant (i.e. having a distribution invariant under the left and right actions of the unitary groups) such that the symmetrization of the singular law of $M(n)$ (resp. of $N(n)$ ) converges weakly in probability to $\mu$ (resp. $\nu$ ). Then the symmetrization of the singular law of $M(n)+N(n)$ converges weakly in probability to a probability measure which depends only on $\mu, \nu$, and $\lambda$, denoted by $\mu_{\boxplus_{\lambda}} \nu$, and called the rectangular free convolution with ratio $\lambda$ of $\mu$ and $\nu$.

In the present paper, we study the notion of infinite divisibility for $\boxplus_{\lambda}$, which leads to a LévyKinchine formula for the rectangular $R$-transform (whose definition we shall recall in section (1)): a symmetric probability measure $\mu$ is $\boxplus_{\lambda}$-infinitely divisible if and only if there exists a positive finite symmetric measure $G$ (called its Lévy measure) such that the rectangular $R$-transform with ratio $\lambda$ of $\mu$ is given by the formula:

$$
C_{\mu}(z)=z \int_{\mathbb{R}} \frac{1+t^{2}}{1-z t^{2}} \mathrm{~d} G(t) .
$$

Therefore we can define a bijection $\Lambda_{\lambda}$ between the set of classical symmetric infinitely divisible distributions and the set of $\boxplus_{\lambda}$-infinitely divisible distributions: $\Lambda_{\lambda}$ maps a symmetric $*$-infinitely divisible distribution to the $\boxplus_{\lambda}$-infinitely divisible distribution with the same Lévy measure. This bijection happens, like the one of Bercovici and Pata (BPB99]) between $*$ - and $\boxplus$-infinitely divisible distributions, to have deep properties. It is a semi-groups morphism:

$$
\Lambda_{\lambda}(\mu * \nu)=\Lambda_{\lambda}(\mu)_{\boxplus_{\lambda}} \Lambda_{\lambda}(\nu)
$$

and it preserves limit theorems: for all sequences $\left(\mu_{n}\right)$ of symmetric distributions and $\left(k_{n}\right)$ of positive integers tending to infinity, we have, for all probability measure $\mu$,

$$
\mu_{n}^{* k_{n}} \underset{n \rightarrow \infty}{\longrightarrow} \mu \Longleftrightarrow \mu_{n}^{\boxplus \lambda^{\prime} k_{n}} \underset{n \rightarrow \infty}{\longrightarrow} \Lambda_{\lambda}(\mu) .
$$

$\Lambda_{\lambda}$ will be called the rectangular Bercovici-Pata bijection with ratio $\lambda$.
In the section $\|^{\square}$, we characterize the image, by $\Lambda_{\lambda}$, of the standard Gaussian distribution: when $\lambda>0$, it has density

$$
\frac{\left[4 \lambda-\left(x^{2}-1-\lambda\right)^{2}\right]^{1 / 2}}{2 \pi \lambda|x|}
$$

on its support $\left[-1-\lambda^{1 / 2},-1+\lambda^{1 / 2}\right] \cup\left[1-\lambda^{1 / 2}, 1+\lambda^{1 / 2}\right]$. An interesting interpretation of this result is made in a forthcoming paper (B-G2]) where we construct analogues of Voiculescu's free entropy and free Fisher information for operators between different Hilbert spaces, and where the maximum of entropy and the minimum of Fisher information are realized for operators which absolute value has this (symmetrized) distribution. Another consequence of this result is a new formula for the moments of the Marchenko-Pastur distribution (which is closely related to this distribution): for all $a>0$, for all $n \geq 1$, the $n$-th moment of the Marchenko-Pastur distribution with parameter $a$ (see HP00 p. 65) is equal to $\sum_{\pi} a^{o(\pi)}$, where the sum is taken over all noncrossing pairings of [2n], and where $o(\pi)$ is the number of blocks of a partition $\pi$ which first element is odd.

In section 5, we shall construct a matricial model for the $\mathbb{T}_{\lambda}$-infinitely divisible laws and present in a maybe more palpable way the Bercovici-Pata bijection with ratio $\lambda$ (whereas the proofs of the other sections rely on integral transforms and complex analysis): we are going to construct, in the same way as in B-G04 and in C-D04, for each $d, d^{\prime} \geq 1$, for each symmetric *-infinitely divisible distribution $\mu$, an infinitely divisible distribution $\mathbb{P}_{d, d^{\prime}}^{\mu}$ on the set of $d \times d^{\prime}$ complex matrices such that for all $\mu, \nu, \mathbb{P}_{d, d^{\prime}}^{\mu} * \mathbb{P}_{d, d^{\prime}}^{\nu}=\mathbb{P}_{d, d^{\prime}}^{\mu * \nu}$ and such that the symmetrization of the singular law of $M$ (with $M$ random matrix distributed according to $\mathbb{P}_{d, d^{\prime}}^{\mu}$ ) goes from $\mu$ to its image by the rectangular Bercovici-Pata bijection with ratio $\lambda$ when $d, d^{\prime} \rightarrow \infty, \frac{d}{d^{\prime}} \rightarrow \lambda$.

In the last section, we shall give a representation of the image of the symmetric Poisson distribution by the rectangular Bercovici-Pata bijection with ratio $\lambda$ as the distribution of the absolute value of sums of rank-one matrices.

Aknowledgements. We would like to thank Philippe Biane, our advisor, for usefull discussions. Also, we would like to thank Cécile Martineau for her contribution to the english version of this paper.

## 1. Preliminaries

In this section, we shall recall definition and basic results from B-G1 about the rectangular $R$-transform $C_{\mu}$ of a symmetric probability measure $\mu$.

Let us denote by $z \mapsto z^{1 / 2}$ (resp. $z \mapsto \sqrt{z}$ ) the analytic version of the square root on the complement of the real non positive (resp. non negative) half line such that $1^{1 / 2}=1$ (resp. $\sqrt{-1}=i$ ). Let us define the analytic function function on a neighborhood of zero $U(z)=\frac{-\lambda-1+\left[(\lambda+1)^{2}+4 \lambda z\right]^{1 / 2}}{2 \lambda}$ (when $\lambda=0, U(z)=z$ ). Then one can summarize the different steps of the construction of the rectangular $R$-transform with ratio $\lambda$ in the following chain

$$
\begin{aligned}
& \underset{\substack{\text { sym. prob. } \\
\text { measure }}}{\mu} \longrightarrow G_{\mu}(z)=\int_{\text {Cauchy transform }} \frac{\mathrm{d} \mu(t)}{z-t} \longrightarrow H_{\mu}(z)=\lambda G_{\mu}\left(\frac{1}{\sqrt{z}}\right)^{2}+(1-\lambda) \sqrt{z} G_{\mu}\left(\frac{1}{\sqrt{z}}\right) \longrightarrow \\
& C_{\mu}(z)=U\left(\frac{z}{H_{\mu}^{-1}(z)}-1\right) \\
& \quad \text { rect. } R \text {-transf. with ratio } \lambda
\end{aligned}
$$

where $H_{\mu}^{-1}$ is the inverse (for composition) of $H_{\mu}$. Proposition 1.1 and theorem 1.2 bellow, which have first been established in [B-G1], prove that such an inverse exists, give its domain, and prove that for any tight set $A$ of symmetric probability measures, the properties and the domains of the functions $H_{\mu}^{-1}(\mu \in A)$ are "uniform".

Proposition 1.1. Let $A$ be a set of symmetric probability measures on the real line. Then the following assertions are equivalent
(i) $A$ is tight,
(ii) for every $0<\theta<\pi, \lim _{\substack{z \rightarrow 0 \\ \arg z-\pi \mid<\theta}} \frac{1}{z} H_{\mu}(z)=1$ uniformly in $\mu \in A$,
(iii) $\lim _{\substack{x \rightarrow 0 \\ x \in(-\infty, 0)}} \frac{1}{x} H_{\mu}(x)=1$ uniformly in $\mu \in A$.

Define, for $\alpha \in(0, \pi), \beta>0, \Delta_{\alpha, \beta}$ to be the set of complex numbers $z$ such that $|\arg z-\pi|<\alpha$ and $|z|<\beta$.

Let $\mathcal{H}$ be the set of functions $f$ which are analytic in a domain $\mathcal{D}_{f}$ such that for all $\alpha \in(0, \pi)$, there exists $\beta$ positive such that

$$
\Delta_{\alpha, \beta} \subset \mathcal{D}_{f}
$$

A family $\left(f_{a}\right)_{a \in A}$ of functions of $\mathcal{H}$ is said to be uniform if for all $\alpha \in(0, \pi)$, there exists $\beta$ positive such that

$$
\forall a \in A, \quad \Delta_{\alpha, \beta} \subset \mathcal{D}_{f_{a}}
$$

Theorem 1.2. Let $\left(H_{a}\right)_{a \in A}$ be a uniform family of functions of $\mathcal{H}$ such that for every $\alpha \in(0, \pi)$,

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{H_{a}(z)}{z}=1 \text { uniformly in } a \in A .
$$

Then there exists a uniform family $\left(F_{a}\right)_{a \in A}$ of functions of $\mathcal{H}$ such that for every $\alpha \in(0, \pi)$,

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{F_{a}(z)}{z}=1 \text { uniformly in } a \in A,
$$

and there exists $\beta$ positive such that

$$
\forall a \in A, \quad H_{a} \circ F_{a}=F_{a} \circ H_{a}=I_{d} \text { on } \Delta_{\alpha, \beta}
$$

Moreover, the family $\left(F_{a}\right)_{a \in A}$ is unique in the following sense: if a family $\left(\tilde{F}_{a}\right)_{a \in A}$ of functions of $\mathcal{H}$ satisfies the same conditions, then for all $\alpha \in(0, \pi)$, there exists $\beta$ positive such that

$$
\forall a \in A, \quad F_{a}=\tilde{F}_{a} \text { on } \Delta_{\alpha, \beta}
$$

Using the theory of cumulants in operator-valued free probability theory, we prove (equation (42) of B-G1) the additivity of rectangular $R$-transform: for all $\mu, \nu$, symmetric probability measures, we have

$$
C_{\mu \boxplus_{\lambda} \nu}=C_{\mu}+C_{\nu} .
$$

We shall mention here two other results, proved in B-G1. The second of them allows us to claim that $\boxplus_{\lambda}$ is continuous with respect to weak convergence.
Lemma 1.3 (Tightness and rectangular $R$-transform). Let $A$ be a set of symmetric probability measures. Then we have equivalence between:
(i) $A$ is tight,
(ii) for any $0<\alpha<\pi, \lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} C_{\mu}(z)=0$ uniformly in $\mu \in A$,
(iii) $\lim _{\substack{x \rightarrow 0 \\ x \in(-\infty, 0)}} C_{\mu}(x)=0$ uniformly in $\mu \in A$.

Theorem 1.4 (Paul Lévy's theorem for rectangular $R$-transform). Let $\left(\mu_{n}\right)$ be a sequence of symmetric probability measures. Then we have equivalence between:
(i) $\left(\mu_{n}\right)$ converges weakly to a symmetric probability measure;
(ii) there exists $\alpha, \beta$ such that
(a) $\lim _{\substack{z \rightarrow 0 \\|\arg z-0|<\alpha}} C_{\mu_{n}}(z)=0$ uniformly in $n$,
(b) the sequence $\left(C_{\mu_{n}}\right)$ converges uniformly on every compact set of $\Delta_{\alpha, \beta}$ when $n \rightarrow \infty$;
(iii) (a) $\lim _{\substack{x \rightarrow 0 \\ x \in(-\infty, 0)}} C_{\mu_{n}}(x)=0$ uniformly in $n$,
（b）there exists $\beta>0$ such that the sequence $\left(C_{\mu_{n}}\right)$ converges pointwise on $[-\beta, 0)$ when $n \rightarrow \infty$ ．

Moreover，in this case，denoting by $\mu$ the weak limit of $\left(\mu_{n}\right)$ ，for every $\alpha$ ，there exists $\beta$ such that the sequence $\left(C_{\mu_{n}}\right)$ converges uniformly to $C_{\mu}$ on every compact set of $\Delta_{\alpha, \beta}$ when $n \rightarrow \infty$ ．

## 2．Lévy－Kinchine Formula For m $_{\lambda}$－Infinitely divisible distributions

$\boxplus_{\lambda}$－infinitely divisible distributions are defined in the same way as $*$－and $⿴ 囗 十$－infinitely divisible distributions：

Definition 2．1．A symmetric probability measure $\nu$ is said to be $\boxplus_{\lambda}$－infinitely divisible if for each $n \in \mathbb{N}^{*}$ ，there exists a symmetric distribution $\nu_{n}$ such that $\nu_{n}^{\boxplus{ }_{\lambda} n}=\nu$ ．

As for $*-$ and $\boxplus$－，we have the following characterization of $\boxplus_{\lambda}$－infinite divisibility．
Theorem 2．2．Let $\nu$ be a symmetric distribution．Then $\nu$ is $\boxplus_{\lambda}$－infinitely divisible if and only if there exists a sequence $\left(\nu_{n}\right)$ such that $\nu_{n}^{\boxplus_{\lambda} n}$ converges weakly to $\nu$ ．

Proof．If $\nu$ is $\boxplus_{\lambda}$－infinitely divisible，it is clear．Assume the existence of a sequence $\left(\nu_{n}\right)$ such that $\nu_{n}{ }_{\lambda} n$ converges weakly to $\nu$ ．Consider $k \geq 1$ ．Let us show that their exists a symmetric probability measure $\sigma$ such that $\sigma^{\boxplus} k=\nu$ ．We have $\lim _{\substack{y \rightarrow 0 \\ y<0}} n C_{\nu_{n}}(y)=0$ uniformly in $n$ ，so $\lim _{\substack{y \rightarrow 0 \\ y<0}} n C_{\nu_{k n}}(y)=0$ uniformly in $n$ ．So by lemma 1．3，the sequence $\left(\nu_{k n}^{\boxplus{ }_{\lambda} n}\right)$ is tight．If the symmetric distribution $\sigma$ is the limit of one of its subsequences，we have

$$
\sigma^{\boxplus_{\lambda} k}=\lim \left(\nu_{k n}^{\boxplus{ }_{\lambda}} n\right)^{\boxplus \boxplus_{\lambda} k}=\lim \nu_{k n}^{\boxplus{ }_{\lambda}} n k=\nu .
$$

Corollary 2．3．The set of $\boxplus_{\lambda}$－infinitely divisible distributions is closed under weak convergence．

Proof．If a sequence $\left(\mu_{n}\right)$ of $\boxplus_{\lambda}$－infinitely divisible distributions converges weakly to a distribu－ tion $\mu$ ，then if for every $n, \nu_{n}^{\boxplus{ }_{\lambda}}=\mu_{n}$ ，the sequence $\left(\nu_{n}^{\boxplus_{\lambda} n}\right)$ converges weakly to $\mu$ ．

To prove the Lévy－Kinchine formula for $\boxplus_{\lambda}$－infinitely divisible distributions，we need the fol－ lowing lemma，which is the analogue of propositions 2.6 and 2.7 of BPB99］．

Lemma 2．4．Let $\left(\nu_{n}\right)$ be a sequence of measures that converges weakly to $\delta_{0}$ ．Consider $\alpha \in$ $(0, \pi)$ ．Then there exists $\beta>0$ such that on $\Delta_{\alpha, \beta}$ ，

$$
C_{\nu_{n}}(z)=\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)\left(1+v_{n}(z)\right)
$$

where the functions $v_{n}$ ，defined on $\Delta_{\alpha, \beta}$ ，are such that
（i）$\forall n, \forall z,\left|v_{n}(z)\right| \leq 1 / 2$ and $\lim _{z \rightarrow 0} v_{n}(z)=0$ uniformly in $n$ ，
（ii）$\forall z, \lim _{n \rightarrow \infty} v_{n}(z)=0$ ．

Proof. First, note that unless $\nu_{n}=\delta_{0}$ (in which case $v_{n}=0$ is suitable), for all $z$, $\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1 \neq 0$, so there is a function $v_{n}$ on the domain of $C_{\nu_{n}}$ such that

$$
C_{\nu_{n}}(z)=\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)\left(1+v_{n}(z)\right) .
$$

To prove ( $i$ ), we will only use the tightness of $\left\{\nu_{n} ; n \in \mathbb{N}\right\}$. It suffices to show that

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{C_{\nu_{n}}(z)}{\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1}=1 \text { uniformly in } n .
$$

We have

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)=1 \text { uniformly in } n,
$$

and when a complex number $t$ tends to $1, t-1 \sim\left(\lambda t^{2}+(1-\lambda) t-1\right) /(\lambda+1)$, so it suffices to show that

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{(\lambda+1) C_{\nu_{n}}(z)}{\frac{H_{\nu_{n}}(z)}{z}-1}=1 \text { uniformly in } n .
$$

We have

$$
\frac{H_{\nu_{n}}(z)}{z}-1=\frac{H_{\nu_{n}}(z)}{z}\left(1-\frac{z}{H_{\nu_{n}}(z)}\right),
$$

and we know, by lemma 1.3, that

$$
\begin{equation*}
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{H_{\nu_{n}}(z)}{z}=1 \text { uniformly in } n . \tag{2.1}
\end{equation*}
$$

So it suffices to show that

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{(\lambda+1) C_{\nu_{n}}(z)}{1-\frac{z}{H_{\nu_{n}}(z)}}-1=0 \text { uniformly in } n .
$$

We know, by proposition 1.1 and by theorem 1.2, that

$$
\begin{equation*}
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{H_{\nu_{n}}^{-1}(z)}{z}=1 \text { uniformly in } n \tag{2.2}
\end{equation*}
$$

and the equivalent of $U(x)$ in the neighborhood of zero is $\frac{x}{\lambda+1}$. So, since $C_{\nu_{n}}=U\left(\frac{z}{H_{\nu_{n}}^{-1}(z)}-1\right)$, it suffices to show that

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{\frac{z}{H_{\nu_{n}^{\prime}}^{1}(z)}-1}{1-\frac{z}{H_{\nu_{n}}(z)}}=1 \text { uniformly in } n .
$$

Choose $\alpha^{\prime} \in(\alpha, \pi)$. By theorem 1.2, there exists $\beta_{1}>0$ such that for all $n, H_{\nu_{n}}^{-1}$ is defined on $\Delta_{\alpha^{\prime}, 2 \beta_{1}}$, and

$$
H_{\nu_{n}}\left(\Delta_{\alpha, \beta_{1}}\right) \cup H_{\nu_{n}}^{-1}\left(\Delta_{\alpha, \beta_{1}}\right) \subset \Delta_{\alpha^{\prime}, 2 \beta_{1}} .
$$

We have, for $z \in \Delta_{\alpha, \beta_{1}}$,

$$
\begin{aligned}
\frac{\frac{z}{H_{\nu_{n}^{1}}^{1}(z)}-1}{1-\frac{z}{H_{\nu_{n}}(z)}}-1 & =\frac{\frac{z H_{\nu_{n}}(z)}{H_{\nu_{n}^{1}}^{1}(z)}-H_{\nu_{n}}(z)}{H_{\nu_{n}}(z)-z}-1 \\
& =\frac{1}{H_{\nu_{n}}(z)-z} \int_{\left[z, H_{\nu_{n}}(z)\right]} f_{n}^{\prime}(\xi) \mathrm{d} \xi
\end{aligned}
$$

where $f_{n}$ is the function defined by

$$
f_{n}(\xi)=\frac{H^{-1}(\xi) H(z)}{H^{-1}(z)}-\xi
$$

But the lemma 2.4 of [BPB99] states that

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha^{\prime}}}\left(H_{\nu_{n}}^{-1}\right)^{\prime}(z)=1 \text { uniformly in } n .
$$

Hence, using also (2.1) and (2.2) (which stay true if $\alpha$ is replaced by $\alpha^{\prime}$ ), we have

$$
\lim _{\substack{\xi \rightarrow 0 \\|\arg \xi-\pi|<\alpha^{\prime}}} f_{n}^{\prime}(\xi)=0 \text { uniformly in } n .
$$

so

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} \frac{\frac{z}{H_{\nu_{n}^{\prime}}^{1}(z)}-1}{1-\frac{z}{H_{\nu_{n}}(z)}}=1 \text { uniformly in } n .
$$

So we know that there exists a sequence $\left(v_{n}\right)$ of functions such that $(\lambda+1) C_{\nu_{n}}(z)=\frac{H_{\nu_{n}}(z)}{z}-1$ (which implies $C_{\nu_{n}}(z)=\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)\left(1+v_{n}(z)\right)$ ) and $\lim _{z \rightarrow \infty} v_{n}(z)=0$ uniformly in $n$. Hence we can choose $\beta_{2}$ such that $\forall n, \forall z \in \Delta_{\alpha, \beta_{2}},\left|v_{n}(z)\right| \leq 1 / 2$.

Let us now prove (ii). First, note that since $\nu_{n} \rightarrow \delta_{0}$, the sequence ( $G_{\nu_{n}}$ ) converges uniformly to $G_{\delta_{0}}: z \mapsto 1 / z$ on every compact of the upper half plane (see A61] or section 3.1 of HP00]), so, as in the proof of $(i)$, it suffices to show that

$$
\lim _{n \rightarrow \infty} \frac{(\lambda+1) C_{\nu_{n}}(z)}{\frac{H_{\nu n}(z)}{z}-1}=1
$$

The convergence of $\nu_{n}$ to $\delta_{0}$ implies too that $\left(H_{\nu_{n}}\right)$ converges to $H_{\delta_{0}}: z \mapsto z$. So, since

$$
\frac{H_{\nu_{n}}(z)}{z}-1=\frac{H_{\nu_{n}}(z)}{z}\left(1-\frac{z}{H_{\nu_{n}}(z)}\right),
$$

it suffices to prove that

$$
\lim _{n \rightarrow \infty} \frac{(\lambda+1) C_{\nu_{n}}(z)}{1-\frac{z}{H_{\nu_{n}}(z)}}=1
$$

Furthermore, by theorem 1.4, there exists $\beta_{3} \leq \beta_{2}$ such that the sequence $C_{\nu_{n}}$ converges uniformly to $C_{\delta_{0}}=0$ on every compact of $\Delta_{\alpha, \beta_{3}}$. So $z / H_{\nu_{n}}^{-1}(z)=\left(\lambda C_{\nu_{n}}(z)+1\right)\left(C_{\nu_{n}}(z)+1\right)$ converges uniformly to 1 on every compact of $\Delta_{\alpha, \beta_{3}}$. So, since $(\lambda+1) U(z)$ is equivalent to $z$ as $z$ tends to zero and since $C_{\nu_{n}}=U\left(z / H_{\nu_{n}}^{-1}(z)-1\right)$, it suffices to show that for all $z \in \Delta_{\alpha, \beta_{3}}$,

$$
\lim _{n \rightarrow \infty} \frac{\frac{z}{H_{\nu_{n}}^{1}(z)}-1}{1-\frac{z}{H_{\nu_{n}}(z)}}=1
$$

As in the proof of $(i)$, let us choose $\beta<\beta_{3} / 2$ such that for all $n$, $H_{\nu_{n}}^{-1}$ is defined on $\Delta_{\alpha^{\prime}, \beta}$, $H_{\nu_{n}}\left(\Delta_{\alpha, \beta}\right) \cup H_{\nu_{n}}^{-1}\left(\Delta_{\alpha, \beta}\right) \subset \Delta_{\alpha^{\prime}, 2 \beta}$, and

$$
\lim _{n \rightarrow \infty} \frac{H_{\nu_{n}}^{-1}(z)}{z}=1 \text { uniformly on every compact of } \Delta_{\alpha^{\prime}, 2 \beta}
$$

By analycity of the $H_{\nu_{n}}^{-1}$ 's, the last assertion implies that

$$
\lim _{n \rightarrow \infty}\left(H_{\nu_{n}}^{-1}\right)^{\prime}(z)=1 \text { uniformly on every compact of } \Delta_{\alpha^{\prime}, 2 \beta}
$$

We have, for $z \in \Delta_{\alpha, \beta}$,

$$
\begin{aligned}
& \frac{z}{\frac{z}{H_{\nu_{n}^{1}}^{1}(z)}-1} \\
& 1-\frac{z}{H_{\nu_{n}}(z)}=\frac{\frac{z H_{\nu_{n}}(z)}{H_{\nu_{n}^{1}}^{1}(z)}-H_{\nu_{n}}(z)}{H_{\nu_{n}}(z)-z}-1 \\
&=\frac{1}{H_{\nu_{n}}(z)-z} \int_{\left[z, H_{\nu_{n}}(z)\right]} f_{n}^{\prime}(\xi) \mathrm{d} \xi
\end{aligned}
$$

where $f_{n}$ is still the function defined by

$$
f_{n}(\xi)=\frac{H^{-1}(\xi) H(z)}{H^{-1}(z)}-\xi
$$

$f_{n}^{\prime}$ tends to zero as $n$ tends to infinity, uniformly on every compact of $\Delta_{\alpha^{\prime}, 2 \beta}$, so

$$
\frac{\frac{z}{H_{\nu_{n}}^{-1}(z)}-1}{1-\frac{z}{H_{\nu_{n}}(z)}}-1
$$

tends to zero when $n$ tends to infinity, and the result is proved.
In the following, we shall refer to weak convergence for sequences of positive finite measures on the real line: that is convergence for which the test functions are the continuous bounded functions.

Theorem 2.5 (Lévy-Kinchine formula, part 1). Let $\mu$ be a symmetric probability measure, $\left(\nu_{n}\right)$ be a sequence of symmetric probability measures and $k_{n}$ a sequence of integers tending to infinity such that $\nu_{n}^{\boxplus}{ }^{k_{n}}$ converges weakly to $\mu$. Then there exists a symmetric positive finite measure $G$ such that
(1) the sequence of positive finite measures $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ converges weakly to $G$,
(2) the $R$-transform of $\mu$ has an analytic continuation to the complement of the real nonnegative half line and is given by the formula

$$
\begin{equation*}
C_{\mu}(z)=z \int_{\mathbb{R}} \frac{1+t^{2}}{1-z t^{2}} \mathrm{~d} G(t) . \tag{2.3}
\end{equation*}
$$

Moreover, $G$ is symmetric and is the only positive finite measure $F$ such that

$$
C_{\mu}(z)=z \int_{\mathbb{R}} \frac{1+t^{2}}{1-z t^{2}} \mathrm{~d} F(t) .
$$

## Proof.

(1) The sequence $\left(\nu_{n}\right)$ converges weakly to $\delta_{0}$. Indeed, for every $n, C_{\nu_{n} \lambda^{k}}=k_{n} C_{\nu_{n}}$, and by theorem 1.4, we have
(a) $\lim _{\substack{x \rightarrow 0 \\ x<0}} k_{n} C_{\nu_{n}}(x)=0$ uniformly in $n$,
(b) There exists $\beta>0$ such that the sequence $\left(k_{n} C_{\nu_{n}}\right)$ converges pointwise on $(-\beta, 0)$. So
(a) $\lim _{\substack{x \rightarrow 0 \\ x<0}} C_{\nu_{n}}(x)=0$ uniformly in $n$,
(b) there exists $\beta>0$ such that the sequence $\left(C_{\nu_{n}}\right)$ converges pointwise to $0=C_{\delta_{0}}$ on $(-\beta, 0)$.
(2) The sequence of positive finite measures $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ is tight. Indeed, for $y>0$,

$$
\begin{aligned}
\int_{[-1 / y, 1 / / 4]^{c}} k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) & \leq 2 \int_{t \in \mathbb{R}} \frac{1+t^{2}}{y^{-2}+t^{2}} \cdot k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) \\
& =-2 k_{n}\left((i / y) G_{\nu_{n}}(i / y)-1\right) .
\end{aligned}
$$

Let $v_{n}$ be as in the previous lemma. For $y>0$ small enough,

$$
\int_{[-1 / y, 1 / f]^{c}} k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) \leq-\frac{2 k_{n} C_{\nu_{n}}\left(-y^{2}\right)}{1+v_{n}\left(-y^{2}\right)} \leq 4\left|k_{n} C_{\nu_{n}}\left(-y^{2}\right)\right|,
$$

which tends to zero uniformly in $n$ when $y$ tends to zero, by tightness of the sequence $\left(\nu_{n}^{\boxplus{ }_{\lambda}} k_{n}\right)$.
(3) The sequence of positive finite measures $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ is bounded. Indeed, if $y>0$ is such that $-y^{2}$ is in the domain of the $v_{n}$ 's of the previous lemma and $\lim _{n \rightarrow \infty} k_{n} C_{\nu_{n}}\left(-y^{2}\right)=$ $C_{\mu}\left(-y^{2}\right)$, we have, for each $n$,

$$
\begin{aligned}
\int_{t \in \mathbb{R}} k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) & \leq y^{-2} \int_{t \in \mathbb{R}} k_{n} \frac{t^{2}}{y^{-2}+t^{2}} \mathrm{~d} \nu_{n}(t) \\
& =-y^{-2} k_{n}\left((i / y) G_{\nu_{n}}(i / y)-1\right) \\
& =-y^{-2} k_{n} \frac{C_{\nu_{n}}\left(-y^{2}\right)}{1+v_{n}\left(-y^{2}\right)} \\
& \leq 4 y^{-2}\left|k_{n} C_{\nu_{n}}\left(-y^{2}\right)\right|
\end{aligned}
$$

which is bounded uniformly in $n$.
(4) Let us now recall a few facts about the Poisson integral of positive measures on the real line which integrate $1 /\left(1+t^{2}\right)$. If $M$ is such a measure, for $y<0$ and $x \in \mathbb{R}$, let us define

$$
P_{y}(M)(x)=\int_{t \in \mathbb{R}} \frac{y}{y^{2}+(x-t)^{2}} \mathrm{~d} M(t) .
$$

Then $(x+i y) \mapsto P_{y}(M)(x)$ is harmonic and determines the measure $M$ (D74], chapter II, theorem II).
Moreover, an easy computation shows that for each positive symmetric measure $M$ on the real line that integrates $1 /\left(1+t^{2}\right)$, the Poisson integral $P_{y}(M)(x)$ is the imaginary part of $\int_{\mathbb{R}} \frac{\sqrt{z}}{t^{2} z-1} \mathrm{~d} M(t)$ (with $z \notin[0,+\infty), x+i y=1 / \sqrt{z}$, as it will be until the end of this proof). Indeed, since $M$ is symmetric,

$$
\begin{aligned}
\int_{\mathbb{R}} \frac{\sqrt{z}}{t^{2} z-1} \mathrm{~d} M(t)= & \int_{\mathbb{R}} \frac{\sqrt{z}(t \sqrt{z}+1)}{t^{2} z-1} \mathrm{~d} M(t)=\int_{\mathbb{R}} \frac{\sqrt{z}(t \sqrt{z}+1)}{\sqrt{z}(t \sqrt{z}+1)\left(t-\frac{1}{\sqrt{z}}\right)} \mathrm{d} M(t)= \\
& =\int_{\mathbb{R}} \frac{\mathrm{d} M(t)}{t-\frac{1}{\sqrt{z}}}=\int_{\mathbb{R}} \frac{(t-x)+i y}{(t-x)^{2}+y^{2}} \mathrm{~d} M(t) .
\end{aligned}
$$

Now let us compute the Poisson integral of the measures $k_{n} t^{2} \mathrm{~d} \nu_{n}(t)$. Let $\alpha, \beta>0$ and $\left(v_{n}\right)$ be as in the previous lemma, $z \in \Delta_{\alpha, \beta}$. We have

$$
P_{y}\left(k_{n} t^{2} \mathrm{~d} \nu_{n}(t)\right)(x)=\Im\left(\int_{\mathbb{R}} \frac{k_{n} \sqrt{z} t^{2}}{t^{2} z-1} \mathrm{~d} \nu_{n}(t)\right) .
$$

But since $\nu_{n}$ is symmetric, we have

$$
\int_{\mathbb{R}} \frac{k_{n} \sqrt{z} t^{2}}{t^{2} z-1} \mathrm{~d} \nu_{n}(t)=k_{n} \int_{\mathbb{R}} \frac{t(1+\sqrt{z} t)}{(t \sqrt{z}-1)(t \sqrt{z}+1)} \mathrm{d} \nu_{n}(t)=k_{n} \int_{\mathbb{R}} \frac{t \mathrm{~d} \nu_{n}(t)}{t \sqrt{z}-1},
$$

which is equal, by an easy computation, to

$$
-k_{n} \frac{(1 / \sqrt{z}) G_{\nu_{n}}(1 / \sqrt{z})-1}{\sqrt{z}}
$$

So $P_{y}\left(k_{n} t^{2} \mathrm{~d} \nu_{n}(t)\right)(x)=-\Im\left(k_{n} \frac{C_{\nu_{n}}(z)}{\sqrt{z}\left(1+v_{n}(z)\right)}\right)$, which tends to the imaginary part of $-C_{\mu}(z) / \sqrt{z}$, because $\nu_{n}^{\boxplus_{\lambda} k_{n}}$ converges weakly to $\mu$ and $\lim _{n \rightarrow \infty} v_{n}(z)=0$.

The sequence $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$, bounded and tight, is relatively compact in the set of finite positive measures in the real line endowed with the topology of weak convergence (i.e. the topology defined by bounded continuous functions). If two measures $G, H$ are the weak limit of a subsequences of $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$, then the measures $\left(1+t^{2}\right) \mathrm{d} G(t)$ and $\left(1+t^{2}\right) \mathrm{d} H(t)$ have the same Poisson integral on $\sqrt{\Delta_{\alpha, \beta}}$. Indeed, for $z \in \Delta_{\alpha, \beta}$,

$$
P_{y}\left(k_{n} t^{2} \mathrm{~d} \nu_{n}(t)\right)(x)=\int_{t} \underbrace{\frac{y\left(1+t^{2}\right)}{y^{2}+(x-t)^{2}}}_{\begin{array}{c}
\text { continuous } \\
\text { bounded fct of } t
\end{array}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)
$$

tends in the same time to $P_{y}\left(\left(1+t^{2}\right) \mathrm{d} G(t)\right)(x)$, to $P_{y}\left(\left(1+t^{2}\right) \mathrm{d} H(t)\right)(x)$, and to the imaginary part of $-C_{\mu}(z) / \sqrt{z}$. It implies, by harmonicity, that they have the same Poisson integral on the lower half plane, which implies $H=G$. So the sequence $\left(k_{n} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ converges weakly to a measure $G$, such that the Poisson integral $P_{y}\left(\left(1+t^{2}\right) \mathrm{d} G(t)\right)(x)$, is equal to the imaginary part of $-C_{\mu}(z) / \sqrt{z}$. Thus, the functions

$$
C_{\mu}(z) / \sqrt{z} \text { and } \int_{\mathbb{R}} \frac{\sqrt{z}\left(t^{2}+1\right)}{1-t^{2} z} \mathrm{~d} G(t)
$$

have the same imaginary part. For $z \in(-\infty, 0)$, it follows that

$$
C_{\mu}(z) \text { and } z \int_{\mathbb{R}} \frac{t^{2}+1}{1-t^{2} z} \mathrm{~d} G(t)
$$

have the same real part, so, by analycity and since both tend to zero as $z$ goes to zero, they are equal.
(5) If $F$ is another positive finite measure such that $C_{\mu}(z)=z \int_{\mathbb{R}} \frac{t^{2}+1}{1-t^{2} z} \mathrm{~d} F(t)$, then

$$
z \int_{\mathbb{R}} \frac{t^{2}+1}{1-t^{2} z} \mathrm{~d} G(t)=z \int_{\mathbb{R}} \frac{t^{2}+1}{1-t^{2} z} \mathrm{~d} F(t) .
$$

After division by $-\sqrt{z}$ and extraction of the imaginary part, this gives the equality of the Poisson integrals of $\left(1+t^{2}\right) \mathrm{d} G(t)$ and of $\left(1+t^{2}\right) \mathrm{d} F(t)$, which implies $G=F$.

The previous theorem implies that for all $\boxplus_{\lambda}$-infinitely divisible distribution $\mu$, there exists a unique positive finite measure $G$ such that $C_{\mu}$ is given by equation (2.3). $G$ is symmetric (as limit of symmetric measures) and will be called the Lévy measure of $\mu$. By injectivity of
the rectangular $R$-transform, two different probability measures cannot have the same Lévy measure.

Theorem 2.6 (Lévy-Kinchine formula, part 2). Every symmetric positive finite measure on the real line is the Lévy measure of $_{\boxplus_{\lambda} \text {-infinitely }}$ divisible distribution.

Before the proof of the theorem, let us state a result about the way dilation of probability measures modify the rectangular $R$-transform. For $c>0$, let us denote by $D_{c}: x \mapsto c x$. For any distribution $\mu, D_{c}(\mu)$ is the push-forward of $\mu$ by $D_{c}$, i.e. $D_{c}(\mu): B \mapsto \mu\left(c^{-1} B\right)$.

$$
\begin{align*}
& \text { We have } \quad G_{D_{c}(\mu)}=\frac{1}{c} G_{\mu}\left(\frac{z}{c}\right) \text {, } \\
& H_{D_{c}(\mu)}(z)=\frac{\lambda}{c^{2}}\left(G_{\mu}\left(\frac{1}{c \sqrt{z}}\right)\right)^{2}+\frac{(1-\lambda) c \sqrt{z}}{c^{2}} G_{\mu}\left(\frac{1}{c \sqrt{z}}\right)=\frac{1}{c^{2}} H_{\mu}\left(c^{2} z\right), \\
& \text { i.e. } \\
& H_{D_{c}(\mu)}=D_{\frac{1}{c^{2}}} \circ H_{\mu} \circ D_{c^{2}}, \\
& H_{D_{c}(\mu)}^{-1}=D_{\frac{1}{c^{2}}} \circ H_{\mu}^{-1} \circ D_{c^{2}} \text {, } \\
& \text { then } \\
& C_{D_{c}(\mu)}(z)=U\left(\frac{c^{2} z}{H_{\mu}^{-1}\left(c^{2} z\right)}-1\right), \\
& \text { that is } \\
& C_{D_{c}(\mu)}(z)=C_{\mu}\left(c^{2} z\right) . \tag{2.4}
\end{align*}
$$

so

Proof of the theorem. Let us denote by $\mathcal{M}$ the set of symmetric positive finite measures $G$ on the real line such that there exists a symmetric distribution $\mu$ whose rectangular $R$-transform is given by equation (2.3). We will show that $\mathcal{M}$ is the set of symmetric positive finite measures, proving that $c \delta_{0}$ and $c\left(\delta_{u}+\delta_{-u}\right) \in \mathcal{M}$ for all $c, u>0$, that $\mathcal{M}$ is stable by addition, and that $M$ is closed under weak convergence. Note that once this result is proved, it will be clear that any symmetric probability measure with rectangular $R$-transform given by equation (2.3) will be $\boxplus_{\lambda}$-infinitely divisible. Indeed, denoting

$$
C^{(G)}(z)=z \int_{\mathbb{R}} \frac{1+t^{2}}{1-z t^{2}} \mathrm{~d} G(t) \quad(G \in \mathcal{M})
$$

we have $C^{(G)}=n C^{\left(\frac{G}{n}\right)}$.
(1) For every $c>0, c \delta_{0} \in \mathcal{M}$. Indeed, by equation (2.4), if $C^{\left(\delta_{0}\right)}=C_{\mu}$, then for every $c>0$, $C^{\left(c \delta_{0}\right)}=C_{\mu^{\prime}}$, with $\mu^{\prime}=D_{c^{1 / 2}}(\mu)$, so it suffices to show that there exists a symmetric distribution whose rectangular $R$-transform is $C^{\left(\delta_{0}\right)}$. This distribution will appear as the limit in the rectangular free central limit theorem: the sequence $\left.D_{n^{-1 / 2}}\left(\left(\delta_{1}+\delta_{-1}\right) / 2\right)^{\boxplus \lambda^{n}}\right)$ converges weakly to a distribution with rectangular $R$-transform $C^{\left(\delta_{0}\right)}$. The proof is an easy application of additivity of the rectangular $R$-transform, equation (2.4), and theorem 1.4. We will see in the following that it stays true if one replaces $\left(\delta_{1}+\delta_{-1}\right) / 2$ by any symmetric probability measure with variance equal to 1 .
(2) For all $c, u>0, c\left(\delta_{u}+\delta_{-u}\right) \in \mathcal{M}$. Indeed, we have

$$
C^{\left(c\left(\delta_{u}+\delta_{-u}\right)\right)}(z)=2 c \frac{z\left(1+u^{2}\right)}{1-u^{2} z}=2 \frac{c\left(1+u^{2}\right)}{2 u^{2}} \frac{\left(u^{2} z\right)\left(1+1^{2}\right)}{1-\left(u^{2} z\right)}=C^{\left(c^{\prime}\left(\delta_{1}+\delta_{-1}\right)\right)}\left(u^{2} z\right)
$$

where $c^{\prime}=\frac{c\left(1+u^{2}\right)}{2 u^{2}}$. So, by equation (2.4), it suffices to show that for all $c>0$, there exists a distribution whose rectangular $R$-transform is $C^{\left(c\left(\delta_{1}+\delta_{-1}\right)\right)}$. It is the same to prove that there exists a distribution whose rectangular $R$-transform is $C^{\left(\frac{c}{4}\left(\delta_{1}+\delta_{-1}\right)\right)}$. This distribution will appear as the limit in the rectangular free Poisson limit theorem: the
sequence $\nu_{n}{ }^{\boxplus} \lambda^{n}$, with $\nu_{n}=\left(1-\frac{c}{n}\right) \delta_{0}+\frac{c}{2 n}\left(\delta_{1}+\delta_{-1}\right)$, converges weakly to a distribution with rectangular $R$-transform is $C^{\left(\frac{c}{4}\left(\delta_{1}+\delta_{-1}\right)\right)}$.

Indeed, $G_{\nu_{n}}(z)=\frac{z^{2}-1+c / n}{z\left(z^{2}-1\right)}$, so, if $\left(v_{n}\right)$ is a sequence of functions on $\Delta_{\alpha, \beta}$ as in the lemma 2.4, we have

$$
C_{\nu_{n}}(z)=\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)\left(1+v_{n}(z)\right)=\frac{c z}{n(1-z)}\left(1+v_{n}(z)\right),
$$

so for $\mu_{n}=\underbrace{\nu_{n} \boxplus_{\lambda} \cdots \boxplus_{\lambda} \nu_{n}}_{n \text { times }}$,

$$
C_{\mu_{n}}(z)=n C_{\nu_{n}}(z)=\frac{c z}{1-z}\left(1+v_{n}(z)\right) .
$$

So by hypothesis on the functions $v_{n}$, we have both

$$
\lim _{\substack{z \rightarrow 0 \\|\arg z-\pi|<\alpha}} C_{\mu_{n}}(z)=0 \text { uniformly on } n
$$

and

$$
\forall z \in \Delta_{\alpha, \beta}, \lim _{n \rightarrow \infty} C_{\mu_{n}}(z)=\frac{c z}{1-z}=C^{\left(\frac{c}{4}\left(\delta_{1}+\delta_{-1}\right)\right)}(z) .
$$

So, by theorem 1.4, we know that there exists a distribution whose rectangular $R$ transform is $C^{\left(\frac{c}{4}\left(\delta_{1}+\delta_{-1}\right)\right)}$.
(3) $\mathcal{M}$ is stable by addition because $C_{\mu}+C_{\nu}=C_{\mu \boxplus_{\lambda} \nu}$.
(4) $\mathcal{M}$ is closed under weak convergence: let $\left(G_{n}\right)$ be a sequence of $\mathcal{M}$ that converges to a finite measure $G$. Then clearly, the sequence $\left(C^{\left(G_{n}\right)}\right)$ converges pointwise to $C^{(G)}$. So, by theorem 1.4, to prove that $G \in \mathcal{M}$, it suffices to show that

$$
\lim _{\substack{x \rightarrow 0 \\ x<0}} C^{\left(G_{n}\right)}(x)=0 \text { uniformly in } n .
$$

For each $n$ and $x \in(0,1)$, since $G$ is symmetric, $C^{\left(G_{n}\right)}\left(-x^{2}\right)=-\int_{\mathbb{R}} \frac{x^{2}+t^{2} x^{2}}{1+t^{2} x^{2}} \mathrm{~d} G_{n}(t)$,

$$
\forall t \in \mathbb{R}, \frac{x^{2}+t^{2} x^{2}}{1+t^{2} x^{2}} \leq \begin{cases}x(x+1) & \text { if }-1 / x^{1 / 2} \leq t \leq 1 / x^{1 / 2} \\ 1 & \text { elseif. }\end{cases}
$$

So

$$
\left|C^{\left(G_{n}\right)}(x)\right| \leq x(x+1) G_{n}(\mathbb{R})+G_{n}\left(\mathbb{R}-\left[-1 / x^{1 / 2}, 1 / x^{1 / 2}\right]\right),
$$

which tends to zero uniformly in $n$ when $x$ tends to $-\infty$, by boundness and tightness of $\left\{G_{n} ; n \in \mathbb{N}\right\}$.

Both previous theorems together allow us to state the following corollary.
Corollary 2.7. A symmetric probability measure $\mu$ is $\boxplus_{\lambda}$-infinitely divisible if and only if there exists a sequence $\left(\nu_{n}\right)$ of symmetric probability measures and a sequence $\left(k_{n}\right)$ of integers tending to infinity such that the sequence $\left(\nu_{n}^{\boxplus}{ }^{\left(k_{n}\right.}\right)$ tends to $\mu$.

## 3．Rectangular Bercovici－Pata＇s bijection

In this section，we will show that the bijective correspondence between classical symmet－ ric infinitely divisible distributions and rectangular free infinitely divisible distributions is an homeomorphism，and that there exists a correspondence between limit theorems for sums of independent symmetric random variables and sums of free rectangular random variables．

Let us recall a few facts about symmetric＊－infinitely divisible distributions，that can be found in GK54（or F66］，P97］．．．）．A symmetric probability measure $\mu$ on the real line is $*$－infinitely divisible if and only if there exists a finite positive symmetric measure $G$ such that

$$
\forall \xi \in \mathbb{R}, \int_{t \in \mathbb{R}} e^{i t \xi} \mathrm{~d} \mu(t)=\exp \left(\int_{t \in \mathbb{R}}(\cos (t \xi)-1) \frac{1+t^{2}}{t^{2}} \mathrm{~d} G(t)\right)
$$

In this case，such a measure $G$ is unique，and we will call it the Lévy measure of $\mu$ ，and a sequence of symmetric $*$－infinitely divisible distributions converges weakly if and only if the sequence of the corresponding Lévy measures converges weakly．Moreover，in this case，the Lévy measure of the limit will be the limit of the Lévy measures．

We can then define the rectangular Bercovici－Pata bijection with ratio $\lambda$ ，denoted by $\Lambda_{\lambda}$ ，from the set of symmetric $*$－infinitely divisible distributions to the set of $⿴ 囗 十 八_{\lambda}$－infinitely divisible distri－ butions，that maps a $*$－infinitely divisible distribution to the $\boxplus_{\lambda}$－infinitely divisible distribution with the same Lévy measure．Let $\mu, \nu$ be two $*$－infinitely divisible distributions with Lévy measures $G, H$ ．Then the Lévy measures of $\mu * \nu$ and of $\Lambda_{\lambda}(\mu) \boxplus_{\lambda} \Lambda_{\lambda}(\nu)$ are both $G+H$ ，so we have

$$
\Lambda_{\lambda}(\mu * \nu)=\Lambda_{\lambda}(\mu)_{\boxplus_{\lambda}} \Lambda_{\lambda}(\nu) .
$$

Theorem 3．1．The rectangular Bercovici－Pata bijection with ratio $\lambda$ is an homeomorphism， which means that a sequence of $\boxplus_{\lambda}$－infinitely divisible distributions converges weakly if and only if the sequence of the corresponding Lévy measures converges weakly，and in this case，the Lévy measure of the limit is be the limit of the Lévy measures．

Remark 3．2．Note that，for $G$ symmetric positive finite measure，the function $C^{(G)}(z)$ can also be written，by symmetry，

$$
C^{(G)}(z)=\int_{\mathbb{R}} \frac{z+t \sqrt{z}}{1-t \sqrt{z}} \mathrm{~d} G(t) .
$$

Proof．Since the rectangular $R$－transform $C_{\mu}$ with ratio 1 of a symmetric distribution $\mu$ is linked to its Voiculescu transform $\varphi_{\mu}$ by the relation $C_{\mu}(z)=\sqrt{z} \varphi_{\mu}(1 / \sqrt{z})$（see paragraph 5 of ［BV93］for the construction of the Voiculescu transform，and use the fact that for symmetric distributions，the Lévy measure is symmetric to obtain $C_{\mu}(z)=\sqrt{z} \varphi_{\mu}(1 / \sqrt{z})$ ），the previous remark and theorem 5.10 of BV93 shows that the map $\Lambda_{1}$ is the restriction of the＂usual＂ Bercovici－Pata bijection to the set of symmetric distributions．It has been proved in（B－NT02］ that the Bercovici－Pata bijection is an homeomorphism．So the theorem is proved in the case where $\lambda=1$ ．But for every $*$－infinitely divisible distribution $\mu$ ，the formula of the rectangular $R$－transform with ratio $\lambda$ of $\Lambda_{\lambda}(\mu)$ does not depend on $\lambda$ ，so theorem 1.4 allows us to claim that all $\Lambda_{\lambda}$＇s are homeomorphisms．

The next theorem furthers the analogy between the free rectangular convolution and the classical convolution of symmetric measures．As recalled in Theorem 3.3 of BPB99］，It is proved in GK54 that when $\left(\nu_{n}\right)$ is a sequence of symmetric probability measures on the real line and $\left(k_{n}\right)$ is a sequence of integers tending to infinity，the sequence $\left(\nu_{n}^{* k_{n}}\right)$ converges weakly to a $*-$ infinitely divisible distribution if and only if the sequence $\left(\frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ of positive finite measures
converges weakly to its Lévy measure．By the theorem 2．5，we know that it will be the case if the sequence $\left(\nu_{n}{ }^{( } k_{n}\right)$ converges weakly to the image of the $*$－infinitely divisible distribution by the rectangular Bercovici－Pata bijection．The following theorem states the reciprocal implication． So we have，for all $*$－infinitely divisible distribution $\mu$ ，

$$
\begin{equation*}
\left(\nu_{n}^{* k_{n}}\right) \text { converges to } \mu \Longleftrightarrow\left(\nu_{n}^{\boxplus \lambda} k_{n}\right) \text { converges to } \Lambda_{\lambda}(\mu) \tag{3.1}
\end{equation*}
$$

Theorem 3．3．Let $\left(\nu_{n}\right)$ be a sequence of symmetric probability measures on the real line and $\left(k_{n}\right)$ be a sequence of integers tending to infinity．The sequence $\left(\nu_{n}^{* k_{n}}\right)$ converges weakly to an＊－ infinitely divisible distribution if and only if the sequence $\left(\nu_{n}{ }^{( } k_{n}\right)$ converges weakly to its image by the rectangular Bercovici－pata bijection with ratio $\lambda$ ．

Proof．By what precedes，it suffices to prove that if the sequence $\left(\frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ of positive finite measures converges weakly to a finite measure $G$ ，then the sequence $\left(\nu_{n}{ }_{\lambda}{ }^{n}\right)$ converges weakly to the $\boxplus_{\lambda}$－infinitely divisible distribution with Lévy measure $G$ ．Assume the sequence $\left(\frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)\right)$ of positive finite measures to converge weakly to a finite measure $G$ ．
（1）The sequence $\left(\nu_{n}\right)$ converges weakly to $\delta_{0}$ ：
Indeed，for all $\varepsilon>0$ ，as the function $t \mapsto \frac{t^{2}}{1+t^{2}}$ is increasing on $\mathbb{R}^{+}$，we have

$$
\nu_{n}\left([-\varepsilon, \varepsilon]^{c}\right) \leq \frac{1+\varepsilon^{2}}{\varepsilon^{2}} \int_{\mathbb{R}} \frac{t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t),
$$

which tends to zero as $n$ tends to infinity，because the sequence $\left(\frac{k_{n} t^{2}}{1+t^{2}} \nu_{n}(t)\right)$ is bounded．
（2）We have pointwise convergence of the rectangular $R$－transforms：
Let $\alpha, \beta$ and $\left(v_{n}\right)$ be as in the lemma 2．4．On $\Delta_{\alpha, \beta}$ ，we have

$$
\begin{equation*}
C_{\nu_{n}^{\boxplus \lambda^{k}}}(z)=k_{n} C_{\nu_{n}}(z)=k_{n}\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)\left(1+v_{n}(z)\right), \tag{3.2}
\end{equation*}
$$

but we have seen in the proof of theorem 2.5 that

$$
k_{n}\left(\frac{1}{\sqrt{z}} G_{\nu_{n}}\left(\frac{1}{\sqrt{z}}\right)-1\right)=z \int_{\mathbb{R}} \underbrace{\frac{t^{2}+1}{1-t^{2} z}}_{\begin{array}{c}
\text { continuous } \\
\text { bounded fct of } t
\end{array}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t),
$$

so，by pointwise convergence of the sequence $\left(v_{n}\right)$ to zero，the rectangular $R$－transform of $\nu_{n}^{\boxplus \lambda^{k_{n}}}$ converges pointwise to $z \mapsto \int_{\mathbb{R}} \frac{t^{2}+1}{1-t^{2} z} \mathrm{~d} G(t)$ on the set $\Delta_{\alpha, \beta}$ ．
（3）We have $\lim _{\substack{y \rightarrow 0 \\ y>0}} C_{\nu_{n} ⿴ 囗 十 k_{n}}\left(-y^{2}\right)=0$ uniformly in $n$ ：
By equation（3．2）and（ $i$ ）of lemma 2．4，it suffices to prove that

$$
\lim _{\substack{y \rightarrow 0 \\ y>0}} k_{n}\left((i / y) G_{\nu_{n}}(i / y)-1\right)=0 \quad \text { uniformly in } n,
$$

that is，since $\nu_{n}$ is symmetric，

$$
\lim _{\substack{y \rightarrow 0 \\ y>0}} \int_{\mathbb{R}} \frac{y^{2}+t^{2} y^{2}}{1+t^{2} y^{2}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)=0 \quad \text { uniformly in } n
$$

When $y<1, t \mapsto \frac{y^{2}+t^{2} y^{2}}{1+t^{2} y^{2}} \leq 1$ is increasing on $[0, \infty)$, so we have, for every $T>0$,

$$
\int_{\mathbb{R}} \frac{y^{2}+t^{2} y^{2}}{1+t^{2} y^{2}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) \leq \int_{[-T, T]} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)+\frac{y^{2}+T^{2} y^{2}}{1+T^{2} y^{2}} \int_{\mathbb{R}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)
$$

Now fix $\varepsilon>0$, choose $T>0$ such that for all $n, \int_{[-T, T] c} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t) \leq \varepsilon$. For $y$ large enough, $\frac{y^{2}+T^{2} y^{2}}{1+T^{2} y^{2}} \sup _{n} \int_{\mathbb{R}} \frac{k_{n} t^{2}}{1+t^{2}} \mathrm{~d} \nu_{n}(t)$ is less than $\varepsilon$, which closes the proof.

The following corollary could have been proved with the equation (2.4), but the proof we give is shorter and does not use any computations.

Corollary 3.4. The rectangular Bercovici-Pata bijection commutes with the dilations $D_{c}, c>0$.

Proof. Let $\mu$ be a $*$-infinitely divisible distribution. Let, for each $n \geq 1, \nu_{n}$ be a symmetric distribution such that $\nu_{n}^{* n}=\mu$. We have

$$
\begin{aligned}
\Lambda_{\lambda} \circ D_{c}(\mu) & =\Lambda_{\lambda} \circ D_{c}\left(\lim _{n \rightarrow \infty} \nu_{n}^{* n}\right) \\
& =\Lambda_{\lambda}\left(\lim _{n \rightarrow \infty} D_{c}\left(\nu_{n}\right)^{* n}\right) \\
& =\lim _{n \rightarrow \infty} D_{c}\left(\nu_{n}\right)^{\boxplus} n
\end{aligned}
$$

But from equation (2.4) and additivity of the rectangular $R$-transform, we know that

$$
\forall n \geq 1, D_{c}\left(\nu_{n}\right)^{\boxplus_{\lambda} n}=D_{c}\left(\nu_{n}^{\boxplus{ }_{\lambda}} n\right),
$$

so, by continuity of $D_{c}$,

$$
\Lambda_{\lambda} \circ D_{c}(\mu)=D_{c}\left(\lim _{n \rightarrow \infty} \nu_{n}^{\boxplus{ }_{\lambda} n}\right)
$$

which is $D_{c} \circ \Lambda_{\lambda}(\mu)$ by equation (3.1).
So, if we define the $\boxplus_{\lambda}$-stable distributions to be the symmetric distributions whose orbit under the action of the group of the dilations is stable under $\boxplus_{\lambda}$, the rectangular Bercovici-Pata bijection exchanges symmetric $*$-stable and $\boxplus_{\lambda}$-stable distributions. Moreover, the index of any *-stable distribution $\mu$ (i.e. the unique $\alpha \in(0,2]$ such that for all $\left.n \geq 1, \mu^{* n}=D_{n} \frac{1}{\alpha}(\mu)\right)$ is preserved, i.e. one has $\Lambda_{\lambda}(\mu)^{\boxplus{ }_{\lambda}} n=D_{n^{\frac{1}{\alpha}}}\left(\Lambda_{\lambda}(\mu)\right)$.

Remark This remark could be called missed appointment for the Cauchy distribution. The Cauchy type, $\left\{\mathcal{C}_{t}=\frac{1}{\pi} \frac{t \mathrm{~d} x}{x^{2}+t^{2}} ; t>0\right\}$, is well known to be invariant under many transformations. For example, this set is the set of symmetric $*$ - and $\boxplus$-stable distributions with index 1 ( $\mathcal{C}_{t}$ has Lévy measure $\left.t \mathcal{C}_{1}\right)$. But unless $\lambda=1$, the set of $\boxplus_{\lambda}$-stable distributions with index 1 is not the Cauchy type. Indeed, for $t>0$, the rectangular $R$-transform with ratio $\lambda$ of $\Lambda_{\lambda}\left(\mathcal{C}_{t}\right)$ is $i t \sqrt{z}$. On the other hand, from the easy computation $G_{\mathcal{C}_{t}}(z)=1 /(z-i t)$ on the lower half-plane, one has

$$
\begin{aligned}
& H_{\mathcal{C}_{t}}(z)=z \frac{1-(1-\lambda) i t \sqrt{z}}{(1-i t \sqrt{z})^{2}} \text {, and } \\
& \mathcal{C}_{t}=\Lambda_{\lambda}\left(\mathcal{C}_{t}\right) \Leftrightarrow \quad \text { it } \sqrt{z}=U\left(\frac{z}{H_{\mathcal{C}_{t}}^{-1}(z)}-1\right) \\
& \Leftrightarrow \quad(\lambda i t \sqrt{z}+1)(i t \sqrt{z}+1)=\frac{z}{H_{\mathcal{C}_{t}}^{-1}(z)} \\
& \Leftrightarrow H_{\mathcal{C}_{t}}^{-1}(z)=\frac{z}{(\lambda i t \sqrt{z}+1)(i t \sqrt{z}+1)} \\
& \Leftrightarrow H_{\mathcal{C}_{t}}\left(\frac{z}{A(z)}\right)=z, \text { where } A(z)=(\lambda i t \sqrt{z}+1)(i t \sqrt{z}+1) \\
& \Leftrightarrow 1-(1-\lambda) i t V(z)=A(z)\left((1-i t V(z))^{2}, \text { where } V(z)=\sqrt{z / A(z)}\right. \\
& \Leftrightarrow i t V(z)(2 A(z)-1+\lambda)=A(z)-t^{2} z-1 \\
& \Leftrightarrow t^{2} z(2 A(z)-1+\lambda)^{2}=A(z)\left(A(z)-t^{2} z-1\right)^{2},
\end{aligned}
$$

which can be easily verified using a formal calculus program, and which happens to be false unless $\lambda=1$.

Question. Inspired by what happens in the cases $\lambda=0$ and $\lambda=1$, we ask the following question: is there, for each $\lambda$ in $[0,1]$, a functionnal $f_{\lambda}$ from the set of symmetric probability measures on $\mathbb{R}$ to the set of probability measures on $\mathbb{R}$ such that for all $\mu, \nu$ symmetric probability measures, $\mu_{⿴_{\lambda}} \nu$ is the only symmetric probability measure satisfying

$$
f_{\lambda}\left(\mu \boxplus_{\lambda} \nu\right)=f_{\lambda}(\mu) \boxplus_{\lambda}(\nu) \quad ?
$$

Note that in the case $\lambda=1$, the functionnal $f_{\lambda}(\mu)=\mu$ works, and in the case $\lambda=0$, functionnal which maps a measure to its push-forward by the square function works.

## 4. Rectangular Gaussian distribution and Marchenko-Pastur distribution

In this section, we will identify the rectangular Gaussian distribution $\nu$, that is the image, by the rectangular Bercovici-Pata bijection, of the Gaussian distribution with mean zero and variance one. The corresponding Lévy measure is $\delta_{0}$, so the rectangular $R$-transform is $z$. We will show that unless $\lambda=0$, in which case $\nu=\left(\delta_{-1}+\delta_{1}\right) / 2, \nu$ is the symmetric distribution whose push forward by the function $x \rightarrow x^{2}$ has the density

$$
\frac{\left[4 \lambda-(x-1-\lambda)^{2}\right]^{1 / 2}}{2 \pi \lambda x} \chi(x)
$$

where $\chi$ stands for the characteristic function of the interval $\left[\left(1-\lambda^{1 / 2}\right)^{2},\left(1+\lambda^{1 / 2}\right)^{2}\right]$, which means that for all $n \geq 1$, the $2 n$-th moment of $\nu$ is $1 / \lambda$ times the $n$-th moment of the Marchenko-Pastur distribution with expectation $\lambda$ (the Marchenko-Pastur distributions are presented page 65 of HP00).

Recall that the sequence $\left(c_{2 n}(\mu)\right)_{n \geq 1}$ of the free cumulants with ratio $\lambda$ of a symmetric probability measure $\mu$, defined in the very beginning of section 4.1 of [B-G1], are linked to the sequence $\left(m_{n}(\mu)\right)_{n \geq 0}$ of its moments by the relation (proposition 3.5 of B-G1]):

$$
\begin{equation*}
\forall n \geq 1, \quad m_{2 n}(\mu)=\sum_{\pi \in \mathrm{NC}^{\prime}(2 n)} \lambda^{e(\pi)} \prod_{V \in \pi} c_{|V|}(\mu) \tag{4.1}
\end{equation*}
$$

where $\mathrm{NC}^{\prime}(2 n)$ is the set of noncroissing partitions of $\{1, \ldots, 2 n\}$ in which all blocks have even cardinality, and where $e(\pi)$ denotes the number of blocks of $\pi$ with even minimum.

The following lemma will be useful to study distributions coming from rectangular free probability theory. A function $f$ defined on a conjugaison-stable subset of $\mathbb{C}$ is said to be commuting with the conjugaison (abbreviated by c.w.c.) if $f(\bar{z})=\overline{f(z)}$. Note that the function $z \rightarrow z^{1 / 2}$ is c.w.c., whereas $z \rightarrow \sqrt{z}$ is not.

Lemma 4.1. If the rectangular $R$-transform of symmetric probability measure $\mu$ extends to an analytic c.w.c. function in a neighborhood $B(0, r)$ of zero in the complex plane and tends to zero at zero, then the probability measure has compact support, and the expansion of $C_{\mu}(z)$ for small $z$ is given by the formula

$$
\begin{equation*}
C_{\mu}(z)=\sum_{n=1}^{+\infty} c_{2 n}(\mu) z^{n} \tag{4.2}
\end{equation*}
$$

Proof. Let us define $T(z)=(\lambda z+1)(z+1)$. Note that $U$ is the inverse of $T-1$. Since the extension of $C_{\mu}$ tends to zero at zero, $z / H_{\mu}^{-1}(z)$ extends to a neighborhood of zero such that we have, in this neighborhood,

$$
\frac{z}{H_{\mu}^{-1}(z)}=T\left(C_{\mu}(z)\right)
$$

and this function tends to 1 at zero. Thus $H_{\mu}^{-1}(z)$ is one to one in a neighborhood of zero, and $H_{\mu}$ extends to an analytic c.w.c. function in a neighborhood of zero such that

$$
\lim _{z \rightarrow 0} \frac{H_{\mu}(z)}{z}=1
$$

So the function $G_{\mu}(1 / \sqrt{z}) / \sqrt{z}$, which is equal to

$$
\frac{\lambda-1+\left[(1-\lambda)^{2}+4 \lambda\left(H_{\mu}(z) / z\right)\right]^{1 / 2}}{2 \lambda}
$$

if $\lambda>0$ and to $H_{\mu}(z)$ if $\lambda=0$, extends to an analytic c.w.c. function in a neighborhood of zero. But since $\mu$ is symmetric, for all $z$ in the complement of the real nonnegative half line,

$$
\frac{G_{\mu}(1 / \sqrt{z})}{\sqrt{z}}=\frac{1}{\sqrt{z}} \int_{\mathbb{R}} \frac{\mathrm{d} \mu(t)}{\frac{1}{\sqrt{z}}-t}=\frac{1}{2 \sqrt{z}} \int_{\mathbb{R}}\left[\frac{1}{\frac{1}{\sqrt{z}}-t}+\frac{1}{\frac{1}{\sqrt{z}}+t}\right] \mathrm{d} \mu(t)=\int_{\mathbb{R}} \frac{\mathrm{d} \mu(t)}{\frac{1}{z}-t^{2}}=G_{\rho}(1 / z)
$$

where $\rho$ is the push forward of $\mu$ by the function $t \rightarrow t^{2}$. Hence the Cauchy transform of $\rho$ extends to an analytic c.w.c. function in a neighborhood of infinity. Thus, by the Stieltjes inversion formula, $\rho$ is compactly supported, which implies that $\mu$ has compact support too.
$\mu$ has now been proved to be compactly supported. Then the second part of the lemma, equation (4.2), has been established in section 4.1 of B-G1].

So $\nu$ has compact support, and for all $n \geq 1, c_{2 n}(\nu)=\delta_{1, n}$.
Let us first treat the case where $\lambda=0$. By (4.1), all even moment of $\nu$ are 1 , so $\nu=\left(\delta_{-1}+\delta_{1}\right) / 2$.
$\lambda>0$, by (4.1), the moments of $\nu$ are given by

$$
\forall n \geq 1, \quad m_{2 n}(\nu)=\sum_{\pi} \lambda^{e(\pi)}=\lambda^{n} \sum_{\pi}\left(\frac{1}{\lambda}\right)^{o(\pi)}
$$

where the sums are taken over noncrossing pairings of $\{1, \ldots, 2 n\}$ (a noncrossing pairing is a noncrossing partition where all classes have cardinality two, recall also that for $\pi$ partition, $e(\pi)$ and $o(\pi)$ are respectively the number of classes of $\pi$ with even and odd minimum).

Lemma 4.2. Let $I=\left\{x_{1}<\cdots<x_{n}\right\}$ and $J=\left\{y_{1}<z_{1}<y_{2}<z_{2}<\cdots<y_{n}<z_{n}\right\}$ be totally ordered sets. There is a bijection $\pi \rightarrow \ddot{\pi}$ from the set of noncrossing partitions of $I$ to the set of noncrossing pairings of $J$ such that for all $\pi$,

$$
|\pi|=o(\ddot{\pi}) .
$$

Proof. Let us first construct the map $\pi \rightarrow \ddot{\pi}$ by the induction on $n$, using the following well known result : a partition $\pi$ of a finite totally ordered set is noncrossing if and only if one of its class $V$ is an interval and $\pi \backslash\{V\}$ is noncrossing (page 3 of S98]). Consider a noncrossing partition $\pi$ of $I$. If $\pi$ has only one class, we define $\ddot{\pi}$ to be

$$
\left\{\left\{y_{1}, z_{n}\right\},\left\{z_{1}, y_{2}\right\},\left\{z_{2}, y_{3}\right\}, \ldots,\left\{z_{n-1}, y_{n}\right\}\right\} .
$$

In the other case, a strict class $V$ of $\pi$ is an interval, $V=\left\{x_{k}, x_{k+1}, \ldots, x_{l}\right\}$. Then we define $\ddot{\pi}$ to be

$$
\ddot{\sigma} \cup\left\{\left\{y_{k}, z_{l}\right\},\left\{z_{k}, y_{k+1}\right\},\left\{z_{k+1}, y_{k+2}\right\}, \ldots,\left\{z_{l-1}, y_{l}\right\}\right\},
$$

where $\ddot{\sigma}$ is the image (defined by the induction hypothesis) of the partition

$$
\sigma=\pi-\{V\}
$$

of $I-V$ (it is easy to see that the result does not depend on the choice of the interval $V$ ).
The relation $|\pi|=o(\ddot{\pi})$ follows from the construction of $\pi \rightarrow \ddot{\pi}$.
Let us now prove, by induction on $n$, that $\pi \rightarrow \ddot{\pi}$ is a bijection. If $n=1$, the result is obvious. Suppose the result to be proved to the ranks $1, \ldots, n-1$, and consider a noncrossing pairing $\tau$ of $J$. Let us prove that there exists exactly one noncrossing partition $\pi$ of $I$ such that $\ddot{\pi}=\tau$. Consider $l \in[n]$ minimal such that there exists $k<l$ such that $\left\{y_{k}, z_{l}\right\}$ is a class of $\tau$ (such an $l$ exists because it is the case of $n$ ). Then it is easy to see that $\left\{z_{k}, y_{k+1}\right\},\left\{z_{k+1}, y_{k+2}\right\}, \ldots,\left\{z_{l-1}, y_{l}\right\}$ are classes of $\tau$, and any partition $\pi$ of $I$ such that $\ddot{\pi}=\tau$ must satisfy $V:=\left\{x_{k}, x_{k+1}, \ldots, x_{l}\right\} \in \pi$, and

$$
\ddot{\sigma}=\tau-\left\{\left\{y_{k}, z_{l}\right\},\left\{z_{k}, y_{k+1}\right\},\left\{z_{k+1}, y_{k+2}\right\}, \ldots,\left\{z_{l-1}, y_{l}\right\}\right\}
$$

where $\sigma=\pi-\{V\}$ (partition of $I-V$ ). Thus, by the induction hypothesis, there exists exactly one noncrossing partition $\pi$ of $I$ such that $\ddot{\pi}=\tau$.

So the moments of $\nu$ are given by

$$
\forall n \geq 1, \quad m_{2 n}(\nu)=\lambda^{n} \sum_{\pi \in \mathrm{NC}(n)}\left(\frac{1}{\lambda}\right)^{|\pi|} .
$$

But for all $n \geq 1, \sum_{\pi \in \mathrm{NC}(n)}(1 / \lambda)^{|\pi|}$ is the $n$-th moment of a distribution with all free cumulants being equal to $1 / \lambda$, i.e. of the Marchenko-Pastur distribution with parameter $1 / \lambda$ (see HP00] p. 65). Thus the push-forward of $\nu$ by $t \rightarrow t^{2}$ is the push-forward of the Marchenko-Pastur distribution with parameter $1 / \lambda$ by the map $t \rightarrow \lambda t$, and has density

$$
\frac{\left[4 \lambda-(x-1-\lambda)^{2}\right]^{1 / 2}}{2 \pi \lambda x} \chi(x)
$$

where $\chi$ stands for the characteristic function of the interval $\left[\left(1-\lambda^{1 / 2}\right)^{2},\left(1+\lambda^{1 / 2}\right)^{2}\right]$. Hence we have proved the following result:

Theorem 4.3. The rectangular Gaussian distribution $\nu$ with ratio $\lambda>0$ has cumulants given by

$$
\forall n \geq 1, c_{2 n}(\nu)=\delta_{n, 1},
$$

and has density

$$
\frac{\left[4 \lambda-\left(x^{2}-1-\lambda\right)^{2}\right]^{1 / 2}}{2 \pi \lambda|x|} \chi\left(x^{2}\right) .
$$

Its support is $\left[-1-\lambda^{1 / 2},-1+\lambda^{1 / 2}\right] \cup\left[1-\lambda^{1 / 2}, 1+\lambda^{1 / 2}\right]$.
Note that when $\lambda=1$, it is the well-known semi-circle law with radius two.
Remark 4.4 (Moments of the Marchenko-Pastur distribution). Note that the fact that the free cumulants of the Marchenko-Pastur distribution with parameter a (see HP00 p. 65) are all a and the previous lemma give us a formula for its $n$-th moment: it is equal to $\sum_{\pi} a^{o(\pi)}$, where the sum is taken over all noncrossing pairings of $[2 n]$. This formula, proved using a random matrix approach, appeared already in an unpublished paper of Ferenc Oravecz and Dénes Petz.

## 5. A matricial model for the rectangular Bercovici-Pata bijection

In the previous section, the proofs rely on integral transforms and complex analysis. We will construct, in this subsection, a matricial model for the $\boxplus_{\lambda}$-infinitely divisible laws and present in a maybe more palpable way the Bercovici-Pata bijection with ratio $\lambda$.

In this section, $d, d^{\prime}$ will represent dimensions of rectangular matrices, because $n$ will be used to another role. For any distribution $\mathbb{P}$ and any function $f$ on a set of matrices, $\mathbb{E}_{\mathbb{P}}(f(M))$ denotes $\int f(M) \mathrm{d} \mathbb{P}(M)$. Let us recall that the singular law of a matrix $M$ designs the uniform distribution on the spectrum of $|M|:=\left(M M^{*}\right)^{\frac{1}{2}}$. Let us define the symmetrization $\tilde{\mu}$ of a distribution $\mu$ on the real line: it is the distribution which maps a Borel set $B$ to $(\mu(B)+\mu(-B)) / 2$. The symmetrization of the singular law of a matrix $M$ will be denoted by $\tilde{\mu}_{|M|}$.

We are going to construct, in the same way as in B-G04 and in C-D04, for each $d, d^{\prime} \geq 1$, for each symmetric *-infinitely divisible distribution $\mu$, an infinitely divisible distribution $\mathbb{P}_{d, d^{\prime}}^{\mu}$ on the set of $d \times d^{\prime}$ complex matrices such that for all $\mu, \nu, \mathbb{P}_{d, d^{\prime}}^{\mu} * \mathbb{P}_{d, d^{\prime}}^{\nu}=\mathbb{P}_{d, d^{\prime}}^{\mu * \nu}$ and such that the symmetrization of the singular law of $M$ (with $M$ random matrix distributed according to $\left.\mathbb{P}_{d, d^{\prime}}^{\mu}\right)$ goes from $\mu$ to its image by the rectangular Bercovici-Pata bijection with ratio $\lambda$ when $d, d^{\prime} \rightarrow \infty, \frac{d}{d^{\prime}} \rightarrow \lambda$.

Let us introduce the heuristic argument that led us to choose the model we will present. Consider a symmetric $*$-infinitely divisible distribution $\mu$, and two sequences ( $\nu_{n}$ ) (symmetric probability measures), ( $k_{n}$ ) (integers tending to infinity) such that $\nu_{n}^{* k_{n}}$ tends weakly to $\mu$. Define, for each $1 \leq d \leq d^{\prime}$ and each $n \geq 1, \mathbb{Q}_{d, d^{\prime}}^{\nu_{n}}$ to be the law of the $d \times d^{\prime}$ random matrix

$$
U\left[X_{n, i} \delta_{i}^{j}\right]_{\substack{1 \leq i \leq d \\ 1 \leq j \leq d^{\prime}}} V
$$

where $U$ (resp. $V$ ) is a uniform $d \times d$ (resp. $d^{\prime} \times d^{\prime}$ ) unitary random matrix, $X_{n, 1}, \ldots, X_{n, d}$ are distributed according to $\nu_{n}$, and $U, V, X_{n, 1} \ldots$ are independent.

Then if one fixes $n$ and lets $d, d^{\prime}$ go to infinity in such a way that $\frac{d}{d^{\prime}} \rightarrow \lambda$, the symmetrization of the singular law of $M_{1}\left(\nu_{n}\right)+\cdots+M_{n}\left(\nu_{n}\right)$ (with $M_{1}\left(\nu_{n}\right), \ldots, M_{n}\left(\nu_{n}\right)$ independent and distributed according to $\left.\mathbb{Q}_{d, d^{\prime}}^{\nu_{n}}\right)$ goes to $\nu_{n}{ }^{\boxplus} \lambda^{k_{n}}$.

Moreover, if one fixes $d, d^{\prime}$ and lets $n$ go to infinity, the distribution $\left(\mathbb{Q}_{d, d^{\prime}}^{\nu_{n}}\right)^{* k_{n}}$ of $M_{1}\left(\nu_{n}\right)+$ $\cdots+M_{n}\left(\nu_{n}\right)$ converges weakly to a distribution $\mathbb{P}_{d, d^{\prime}}^{\mu}$ on the set of $d \times d^{\prime}$ matrices, whose Fourier
transform is given by the following formula: for all $d \times d^{\prime}$ matrix $A$

$$
\begin{equation*}
\mathbb{E}_{\mathbb{P}_{d, d^{\prime}}^{\mu}}\left(\exp \left(i \Re\left(\operatorname{Tr} A^{*} M\right)\right)\right)=\exp \left(\mathbb{E}\left(d \times \psi_{\mu}(\Re(<u, A v>))\right)\right) \tag{5.1}
\end{equation*}
$$

where $\psi_{\mu}$ is the Lévy exponent of $\mu$, i.e. the unique continuous function $f$ on $\mathbb{R}$ such that $f(0)=0$ and the Fourier transform of $\mu$ is $\exp \circ f,<,$.$\rangle is the canonical hermitian product of \mathbb{C}^{d}$, and $u=\left(u_{1}, \ldots, u_{d}\right), v=\left(v_{1}, \ldots, v_{d^{\prime}}\right)$ are independent random vectors, uniformly distributed on the unit sphere of respectively $\mathbb{C}^{d}, \mathbb{C}^{d^{\prime}}$. The proof of this weak convergence, analogous to the one of theorem 3.1 of B-G04], uses the polar decomposition of $d \times d^{\prime}$ matrices and the bi-unitarily invariance of the distributions $\mathbb{Q}_{d, d^{\prime}}^{\nu_{n}}$. Note that for all $\mu, \nu, \mathbb{P}_{d, d^{\prime}}^{\mu} * \mathbb{P}_{d, d^{\prime}}^{\nu}=\mathbb{P}_{d, d^{\prime}}^{\mu * \nu}$, and that when $\mu=N(0,1), \mathbb{P}_{d, d^{\prime}}^{\mu}$ is the distribution of a matrix $\left[M_{i, j}\right]$ with $\left(\Re M_{i, j}, \Im M_{i, j}\right)_{\substack{1 \leq i \leq d \\ 1 \leq j \leq d^{\prime}}}$ i.i.d. random variables $N\left(0, \frac{1}{2 d^{\prime}}\right)$-distributed i.i.d..

So the convergence of the symmetrization of the singular law of a $\mathbb{P}_{d, d^{\prime}}^{\mu}$-random matrix is the expression of the commutativity of the following diagram:

To prove this result, we need a preliminary result about cumulants of $\boxplus_{\lambda}$-infinitely divisible laws with compactly supported Lévy measure. First, note that by lemma 4.1, such laws are compactly supported. Recall that free cumulants with ratio $\lambda$ have been defined in the beginning of section 0 by (4.1).

Theorem 5.1. Let $\mu$ be $a$ *-infinitely divisible distribution with compactly supported Lévy measure, and let, for $n$ integer, $\mu_{n}$ be a probability measure such that $\mu_{n}^{* n}=\mu$. Then for each $k \geq 1$, the sequence $\left(n \times m_{2 k}\left(\mu_{n}\right)\right)_{n}$ tends to the $2 k$-th classical cumulant $c_{2 k}^{*}(\mu)$ of $\mu$, which is equal to $c_{2 k}\left(\Lambda_{\lambda}(\mu)\right)$.

Proof. Recall that classical cumulants of a probability measure $\nu$ (whose moments of all orders are defined) linearize the classical convolution and are linked to its moments by the formula

$$
\forall k \geq 1, m_{k}(\nu)=\sum_{\pi \in \operatorname{Part}(k)} \prod_{V \in \pi} c_{|V|}^{*}(\nu)
$$

So one has

$$
n \times m_{2 k}\left(\mu_{n}\right)=n \sum_{\pi \in \operatorname{Part}(2 k)} \prod_{V \in \pi} \underbrace{c_{|V|}^{*}\left(\mu_{n}\right)}_{n^{-1} c_{|V|}^{*}(\mu)}=\sum_{\pi \in \operatorname{Part}(2 k)} n^{1-|\pi|} c_{\pi}^{*}(\mu)=c_{2 k}^{*}(\mu)+o(1) .
$$

Let us denote $\nu_{n}=\mu_{n}^{\boxplus} n$. By the line above, for all $k, m_{2 k}\left(\mu_{n}\right)=O\left(n^{-1}\right)$, so $c_{2 k}\left(\mu_{n}\right)=O\left(n^{-1}\right)$, so $c_{2 k}\left(\nu_{n}\right)=O(1)$, and $m_{2 k}\left(\nu_{n}\right)=O(1)$. Moreover, by equation (3.1), the sequence $\left(\nu_{n}\right)$ converges weakly to $\Lambda_{\lambda}(\mu)$. So the moments of $\nu_{n}$ tend to the moments of $\Lambda_{\lambda}(\mu)$ (cf B68]). But
thanks to proposition 3.5 of B-G1,

$$
\begin{aligned}
n \times m_{2 k}\left(\mu_{n}\right) & =n \sum_{\pi \in \mathrm{NC}^{\prime}(2 k)} \lambda^{e(\pi)} \prod_{V \in \pi} \underbrace{c_{|V|}\left(\mu_{n}\right)}_{n^{-1} c_{|V|}\left(\nu_{n}\right)} \\
& =\sum_{\pi \in \mathrm{NC}^{\prime}(2 k)} \lambda^{e(\pi)} n^{1-|\pi|} \prod_{V \in \pi} c_{|V|}\left(\nu_{n}\right)
\end{aligned}
$$

which tends to

$$
\sum_{\pi \in \mathrm{NC}^{\prime}(2 k)} \lambda^{e(\pi)} \delta_{1}^{|\pi|} \prod_{V \in \pi} c_{|V|}\left(\Lambda_{\lambda}(\mu)\right)=c_{2 k}\left(\Lambda_{\lambda}(\mu)\right)
$$

We will first prove the result when $\mu$ has a compactly supported Lévy measure. We will work with a sequence $\left(d_{d}^{\prime}\right)_{d}$ such that $1 \leq d \leq d_{d}^{\prime}$, and $d / d_{d}^{\prime}$ tends to $\lambda \in(0,1]$ (even though the proof can be adaptated to the case $\lambda=0$, we assume that $\lambda>0$ in order to simplify). To simplify notations, $d^{\prime}$ will stand for $d_{d}^{\prime}$.

Proposition 5.2. Let $\mu$ be a symmetric *-infinitely divisible distribution with compactly supported Lévy measure. Then for all integer $k$,
(a) $\lim _{d \rightarrow \infty} \mathbb{E}_{\mathbb{P}_{d, d^{\prime}}^{\mu}}\left(m_{k}\left(\tilde{\mu}_{|M|}\right)\right)=m_{k}\left(\Lambda_{\lambda}(\mu)\right)$.
(b) The variance, under $\mathbb{P}_{d, d^{\prime}}^{\mu}$, of $m_{k}\left(\tilde{\mu}_{|M|}\right)$ tends to zero as d goes to infinity.

Proof. For $n$ integer, $[n]$ will denote $\{1, \ldots, n\}$, and $\mathrm{NC}(n)$ will denote the set of noncrosing partitions of $[n]$. Recall that $\mathrm{NC}^{\prime}(n)$ denotes the set of noncrosing partitions of $[n]$ in which all blocks have even cardinality.
(a) First, for every complex $d \times d$ matrix $M$, for all integer $k, m_{k}\left(\tilde{\mu}_{|M|}\right)$ is null if $k$ is odd and is equal to $\operatorname{tr}\left(M M^{*}\right)^{\frac{k}{2}}\left(\operatorname{tr}\right.$ denotes normalized trace) if $k$ is even. $\Lambda_{\lambda}(\mu)$ is symmetric, so it suffices to show that for all $k \in \mathbb{N}^{*}$,

$$
\lim _{d \rightarrow \infty} \mathbb{E}_{\mathbb{P}_{d, d^{\prime}}^{\mu}}\left(\operatorname{tr}\left(M M^{*}\right)^{k}\right)=m_{2 k}\left(\Lambda_{\lambda}(\mu)\right)
$$

Let, for $n \in \mathbb{N}^{*}, \mu_{n}$ be the probability measure such that $\mu_{n}^{* n}=\mu$. Consider, for $d \geq 1$ and $n \geq 1,\left(M_{d, n}^{(i)}\right)_{1 \leq i \leq n}$ i.i.d. random matrices with distribution $\mathbb{Q}_{d, d^{\prime}}^{\mu_{n}}$. By definition, for every $d \geq 1$, the sum of the $M_{d, n}^{(i)}$ 's $(i=1 \ldots n)$ converges in distribution to $\mathbb{P}_{d, d^{\prime}}^{\mu}$ when $n$ goes to $\infty$. We know, by theorem 5.1 that for all $k \in \mathbb{N}^{*}$, the sequence $\left(n \times m_{k}\left(\mu_{n}\right)\right)_{n}$ is bounded, and so (see B68]) for all $k, d \in \mathbb{N}^{*}$,

$$
\begin{equation*}
\mathbb{E}_{\mathbb{P}_{d, d^{\prime}}^{\mu}}\left(m_{2 k}\left(\tilde{\mu}_{|M|}\right)\right)=\lim _{n \rightarrow \infty} \mathbb{E}\left(\operatorname{tr}\left(\left(\sum_{i=1}^{n} M_{d, n}^{(i)}\right)\left(\sum_{i=1}^{n} M_{d, n}^{(i) *}\right)\right)^{k}\right) \tag{5.2}
\end{equation*}
$$

Let us fix $k \in \mathbb{N}^{*}$.
We are going to use the formula (5.2).
Let, for $d, n \geq 1$,

$$
b_{d, n}=\mathbb{E}\left(\operatorname{tr}\left(\left(\sum_{i=1}^{n} M_{d, n}^{(i)}\right)\left(\sum_{i=1}^{n} M_{d, n}^{(i) *}\right)\right)^{k}\right)
$$

From now on, we do not write anymore the index $d$ in $M_{d, n}^{(i)}$. We denote, for $l, n$ non-negative integers, by $A_{n}^{l}$ the number of one-to-one maps from $[l]$ to $[n]$, i.e. $n(n-1) \cdots(n-l+1)$. For $\pi$ partition of $[2 k]$, for $1 \leq l \leq 2 k$, we denote by $\pi(l)$ the index of the class of $l$, after having ordered the classes according to the order of their first element (for example, $\pi(1)=1 ; \pi(2)=1$ if $1 \stackrel{\pi}{\sim} 2$ and $\pi(2)=2$ if $1 \stackrel{\pi}{\sim} 2$ ). Then we have

$$
\begin{aligned}
b_{d, n}= & \operatorname{tr}\left(\mathbb{E}\left(\sum_{f \in\{1, \ldots, n\}^{2 k}} M_{n}^{(f(1))} M_{n}^{(f(2)) *} \cdots M_{n}^{(f(2 k)) *}\right)\right) \\
= & \operatorname{tr}\left(\mathbb{E}\left(\sum_{\pi \in \operatorname{Part}(2 k)} A_{n}^{|\pi|} M_{n}^{(\pi(1))} M_{n}^{(\pi(2)) *} M_{n}^{(\pi(3))} \cdots M_{n}^{(\pi(2 k)) *}\right)\right) . \\
\text { But } \quad & \mathbb{E}(\underbrace{M_{n}^{(1) *} M_{n}^{(1)} \cdots M_{n}^{(1) *}}_{2 l+1 \text { alterned factors }})=\mathbb{E}(\underbrace{M_{n}^{(1)} M_{n}^{(1) *} \cdots M_{n}^{(1)}}_{2 l+1 \text { alterned factors }})=0, \\
& \mathbb{E}(\underbrace{M_{n}^{(1) *} M_{n}^{(1)} \cdots M_{n}^{(1)}}_{2 l \text { alterned factors }})=\frac{d}{d^{\prime}} m_{2 l}\left(\mu_{n}\right) I_{d^{\prime}}, \\
& \mathbb{E}(\underbrace{M_{n}^{(1)} M_{n}^{(1) *} \cdots M_{n}^{(1) *}}_{2 l \text { alterned factors }})=m_{2 l}\left(\mu_{n}\right) I_{d} .
\end{aligned}
$$

So, using many times the fact that a partition $\pi$ of a finite totally ordered set is noncrossing if and only if one of its class $V$ is an interval and $\pi \backslash\{V\}$ is noncrossing (page 3 of [598]) and integrating successively with respect to the different independent random matrices, one has

$$
\begin{gathered}
\pi \in \mathrm{NC}^{\prime}(2 k) \Rightarrow \operatorname{tr} \mathbb{E}\left(M_{n}^{(\pi(1))} M_{n}^{(\pi(2)) *} \cdots M_{n}^{(\pi(2 k)) *}\right)=\left(\frac{d}{d^{\prime}}\right)^{e(\pi)} \underbrace{\prod_{B \in \pi} m_{|B|}\left(\mu_{n}\right)}_{:=m_{\pi}\left(\mu_{n}\right)}, \\
\pi \in \mathrm{NC}(2 k) \backslash \mathrm{NC}^{\prime}(2 k) \Rightarrow \operatorname{tr} \mathbb{E}\left(M_{n}^{(\pi(1))} M_{n}^{(\pi(2)) *} \cdots M_{n}^{(\pi(2 k)) *}\right)=0 .
\end{gathered}
$$

But $A_{n}^{|\pi|} \sim n^{|\pi|}$, so, by the preceding theorem, the limit, when $n$ goes to infinity, of

$$
\operatorname{tr}\left(\mathbb{E}\left(\sum_{\pi \in \operatorname{Part}(2 k)} A_{n}^{|\pi|} M_{n}^{(\pi(1))} M_{n}^{(\pi(2)) *} \cdots M_{n}^{(\pi(2 k)) *}\right)\right)
$$

is $\sum_{\pi \in \mathrm{NC}^{\prime}(2 k)}\left(\frac{d}{d}\right)^{e(\pi)} m_{\pi}(\mu)$, which tends to $\sum_{\pi \in \mathrm{NC}^{\prime}(2 k)} \lambda^{e(\pi)} m_{\pi}(\mu)=m_{2 k}\left(\Lambda_{\lambda}(\mu)\right)$ when $d$ goes to infinity.

So it suffices to prove that

$$
b_{d, n}^{\prime}:=\sum_{\substack{\pi \in \operatorname{Part}(2 k) \\ \pi \notin \operatorname{NC}(2 k)}} A_{n}^{|\pi|} \operatorname{tr} \mathbb{E}\left\{M_{n}^{(\pi(1))} M_{n}^{(\pi(2)) *} M_{n}^{(\pi(3))} \cdots M_{n}^{(\pi(2 k)) *}\right\}
$$

vanishes when $n$, and then $d$, go to infinity. Let us expand the trace: $b_{n, d}^{\prime}$ is equal to

$$
\frac{1}{d} \sum_{\substack{\pi \in \operatorname{Part}(k) \\ \pi \notin \operatorname{NC}(k) \forall r \text { odd, } j_{r} \leq d}} \sum_{\substack{j \in\left[d^{\prime}{ }^{2 k}\\\\\right.}} A_{n}^{|\pi|} \mathbb{E}\left\{\left[M_{n}^{(\pi(1))}\right]_{j_{1}, j_{2}}\left[M_{n}^{(\pi(2)) *}\right]_{j_{2}, j_{3}} \cdots\left[M_{n}^{(\pi(2 k)) *}\right]_{j_{2 k}, j_{1}}\right\} .
$$

Using the fact that $\left(M_{d, n}^{(i)}\right)_{1 \leq i \leq n}$ are independent copies of a matrix with distribution $\mathbb{Q}_{d, d^{\prime}}^{\mu_{n}}$, we deduce ( with the notation $j_{2 k+1}=j_{1}$ )

$$
\begin{aligned}
b_{d, n}^{\prime}= & \frac{1}{d} \sum_{\substack{\pi \in \operatorname{Part}(k) \\
\pi \notin \mathrm{NC}(k)}} A_{n}^{|\pi|} \sum_{\substack{j \in\left[d^{\prime}\right]^{2 k} \\
\forall r \text { odd, } j_{r} \leq d}} \prod_{B \in \pi} \mathbb{E}_{\mathbb{Q}_{d, d^{\prime}}^{\mu_{n}}}\left\{\prod_{\substack{r \in B \\
r \text { odd }}} M_{j_{r}, j_{r+1}} \prod_{\substack{r \in B \\
r \text { even }}} M_{j_{r}, j_{r+1}}^{*}\right\} \\
= & \frac{1}{d} \sum_{\substack{\pi \in \operatorname{Part}(k) \\
\pi \notin \mathrm{NC}(k)}} \frac{A_{n}^{|\pi|}}{n^{|\pi|}} \sum_{\substack{j \in\left[d^{\prime}\right]^{2 k} \\
\forall r \text { odd, } j_{r} \leq d}} \\
& \prod_{B \in \pi} n \mathbb{E}\left\{\sum_{l \in[d]^{B}} \prod_{\substack{r \in B \\
r \text { odd }}} u_{j_{r}, l_{r}} v_{l_{r}, j_{r+1}} X_{n, l_{r}} \prod_{\substack{r \in B \\
r \text { even }}} \bar{v}_{l_{r}, j_{r}} X_{n, l_{r}} \bar{u}_{j_{r+1}, l_{r}}\right\}
\end{aligned}
$$

where $U, V, X_{n, 1}, \ldots, X_{n, d}$ are independent, with respective distribution the Haar measure on the group of $d \times d$ unitary matrices, the Haar measure on the group of $d^{\prime} \times d^{\prime}$ unitary matrices, and $\mu_{n}$.

For all $B \subset[2 k]$, for all $j \in\left[d^{\prime}\right]^{2 k}$ such that for all $r$ odd, $j_{r} \leq d$, summing over the partition generated by $l$, one has

$$
\begin{gathered}
n \mathbb{E}\left\{\sum_{l \in[d]^{B}} \prod_{\substack{r \in B \\
r \text { odd }}} u_{j_{r}, l_{r}} v_{l_{r}, j_{r+1}} X_{n, l_{r}} \prod_{\substack{r \in B \\
r \text { even }}} \bar{v}_{l_{r}, j_{r}} X_{n, l_{r}} \bar{u}_{j_{r+1}, l_{r}}\right\} \\
=\sum_{\sigma \in \operatorname{Part}(B)} \sum_{l \in[d]^{\sigma}} n^{1-|\sigma|}\left[\prod_{B \in \sigma} n m_{|B|}\left(\mu_{n}\right)\right] \mathbb{E}\left\{\prod_{\substack{r \in B \\
r \text { odd }}} u_{j_{r}, l_{r}} v_{l_{r}, j_{r+1}} \prod_{r \in B}^{r \text { even }} \bar{v}_{l_{r}, j_{r}} \bar{u}_{j_{r+1}, l_{r}}\right\}
\end{gathered}
$$

which tends, according to theorem 5.1, to

$$
\sum_{l=1}^{d} c_{|B|}(\mu) \mathbb{E}\left\{\prod_{\substack{r \in B \\ r \text { odd }}} u_{j_{r}, l} v_{l, j_{r+1}} \prod_{\substack{r \in B \\ r \text { even }}} \bar{v}_{l, j_{r}} \bar{u}_{j_{r+1}, l}\right\}
$$

Which is equal, by invariance of uniform distributions on unitary groups by permutation of rows and columns, to

$$
d \times c_{|B|}(\mu) \mathbb{E}\left\{\prod_{\substack{r \in B \\ r \text { odd }}} u_{j_{r}} v_{j_{r+1}} \prod_{\substack{r \in B \\ r \text { even }}} \bar{v}_{j_{r}} \bar{u}_{j_{r+1}}\right\}
$$

where $u, v$ are independent uniform random vectors on the unit spheres of $\mathbb{C}^{d}, \mathbb{C}^{d^{\prime}}$.

So the limit, when $n$ goes to infinity, of $b_{d, n}^{\prime}$ is

$$
\frac{1}{d} \sum_{\substack{\pi \in \operatorname{Part}(k) \\ \pi \notin \mathrm{NC}(k) \forall r \text { odd, }, j_{r} \leq d}} \sum_{\substack{j \in\left[d^{\prime}\right)^{2 k}}} \prod_{B \in \pi} d \times c_{|B|}(\mu) \mathbb{E}\left\{\prod_{\substack{r \in B \\ r \text { odd }}} u_{j_{r}} v_{j_{r+1}} \prod_{\substack{r \in B \\ r \text { even }}} \bar{v}_{j_{r}} \bar{u}_{j_{r+1}}\right\},
$$

which absolute value is less or equal, by invariance of the distributions of $u$ and $v$ under permutation of coordinates, to

$$
\frac{1}{d} \sum_{\substack{\pi, \tau \in \operatorname{Part}(k) \\ \pi \notin \operatorname{NC}(k)}} d^{||\pi|+|\tau|} c_{\pi}(\mu) \prod_{B \in \pi}\left|\mathbb{E}\left\{\prod_{\substack{r \in B \\ r \text { odd }}} u_{j_{r}} v_{j_{r+1}} \prod_{\substack{r \in B \\ r \text { even }}} \bar{v}_{j_{r}} \bar{u}_{j_{r+1}}\right\}\right|
$$

Moreover, by invariance of the distribution of $u$ under the action of unitary diagonal matrices, for every pair $(\pi, \tau)$ of partitions of [ $2 k$ ], if

$$
\prod_{B \in \pi} \mathbb{E}\left(\prod_{\substack{r \in B \\ r \text { odd }}} u_{\tau(r)} v_{\tau(r+1)} \prod_{\substack{r \in B \\ r \text { even }}} \bar{u}_{\tau(r+1)} \bar{v}_{\tau(r)}\right)
$$

is non zero, then for every class $B$ of $\pi$, there exists $\phi$, permutation of $B$, which maps odd numbers to even numbers and vice versa, such that for all $r \in B, \tau(r)=\tau(\phi(r)+1)$. It implies, by lemma 4.4 of B-G04, that $|\tau|+|\pi| \leq 2 k$. So one has, using the Hölder inequality and equation (4.2.11) of HP00],

$$
\lim _{n \rightarrow \infty} b_{n, d}^{\prime}=O\left(d^{-1}\right)
$$

which closes the proof of (a).
One notes that the proof of $(a)$ is a very closed adaptation of the proof of Proposition 4.1 of B-G04, by adaptation of the arguments to the context of non hermitian and non square matrices. Using again the same adaptation, the proof of $(b)$ is along the same lines as the proof of Proposition 5.1 of B-G04.

To conclude this section, we have to state its main theorem. The proof of the theorem is similar to the one of Theorem 7.6 of [B-G04], based on the previous proposition and on an approximation by compound Poisson laws. The only modification is to work with products of the type $M M^{*}$ rather than $M^{*} M$.

Theorem 5.3. Let $\mu$ be a symmetric *-infinitely divisible distribution. Let, for $d \geq 1, M_{d}$ be a random matrix with distribution $\mathbb{P}_{d, d^{\prime}}^{\mu}$.
Then the symmetrization $\tilde{\mu}_{\left|M_{d}\right|}$ of the singular law of $M_{d}$ converges in probability to $\Psi(\mu)$.
Remark 5.4. In the case where $\mu$ is a normal law, one recovers the well known result about asymptotic spectral distribution of Wishart random matrices.

## 6. Rectangular symmetric Poisson distributions as limits of sums of rank-one MATRICES

Let us define the symmetric Poisson distribution with parameter $a>0$ to be the $*$-infinitely divisible distribution with Lévy measure $\frac{c}{4}\left(\delta_{1}+\delta_{-1}\right)$. It can also be seen as the law of $X-Y$,
where $X, Y$ are independent random variables with (unsymmetric) Poisson law with parameter $c / 2$, or as the weak limit of

$$
\left(\left(1-\frac{c}{n}\right) \delta_{0}+\frac{c}{2 n}\left(\delta_{-1}+\delta_{1}\right)\right)^{* n}
$$

Note that rectangular analogues of Gaussian distributions have been identified to subsection 4, but rectangular analogues of symmetric Poisson distributions are still not characterized, whereas free analogues of (unsymmetric) Poisson distributions are Marchenko-Pastur laws. But the computations for symmetric Poisson laws are harder than for the unsymmetric ones (even for free analogues of symmetric Poisson distributions, the densities are not possible to express). Nevertheless, we have the following characterization of the rectangular analogue of symmetric Poisson distributions.

Proposition 6.1. Consider $\lambda \in(0,1]$, and $c>0$. Then the image, by the Bercovici-Pata bijection with ratio $\lambda$, of the symmetric Poisson distribution with parameter $c$ is the limit, for convergence in probability, of the symmetrization of the singular law of the random matrix

$$
M\left(d, d^{\prime}, d^{\prime \prime}\right):=\sum_{k=1}^{d^{\prime \prime}} u_{d}(k) v_{d^{\prime}}(k)^{*}
$$

when

$$
\begin{equation*}
d \rightarrow \infty, \quad \frac{d}{d^{\prime}} \rightarrow \lambda, \quad \frac{d^{\prime \prime}}{d} \rightarrow c \tag{6.1}
\end{equation*}
$$

where $u_{d}(k), v_{d^{\prime}}(k)(k \geq 1)$ are independent uniform random vectors of the unit spheres of $\mathbb{C}^{d}, \mathbb{C}^{d^{\prime}}$ (considered as column matrices).

Remark 6.2. Note that when $\lambda=1$, the image, by the Bercovici-Pata bijection with ratio $\lambda$, of the symmetric Poisson distribution with parameter $c$ is $\tau_{+} \boxplus \tau_{-}$, where $\tau_{+}$is the MarchenkoPastur distribution with parameter c/2, and $\tau_{-}$is the push-forward, by the function $t \rightarrow-t$, of $\tau_{+}$.

Proof. Let us denote by $\mu$ the symmetric Poisson distribution with parameter $c$, and by $\sigma$ the push-forward by $t \rightarrow t^{2}$ of its image by the Bercovici-Pata bijection with ratio $\lambda$. As explained in the beginning of the proof of theorem 4.6 of B-G1, it suffices to prove that for each $\varepsilon>0$, the probability of the event

$$
\left\{\sup _{\Im z \geq 1}\left|\frac{1}{d} \operatorname{Tr} \Re_{z}\left(A\left(d, d^{\prime}, d^{\prime \prime}\right)\right)-G_{\sigma}(z)\right|>\varepsilon\right\}
$$

tends to zero as $d, d^{\prime}, d^{\prime \prime}$ tend to infinity as in (6.1), where

$$
A\left(d, d^{\prime}, d^{\prime \prime}\right)=M\left(d, d^{\prime}, d^{\prime \prime}\right) M\left(d, d^{\prime}, d^{\prime \prime}\right)^{*}
$$

Fix $\varepsilon>0$. It can easily be seen that $\mathbb{P}_{d, d^{\prime}}^{\mu}$ is the distribution of

$$
N\left(d, d^{\prime}\right):=\sum_{k=1}^{X(c d)} u_{d}(k) v_{d^{\prime}}(k)^{*}
$$

where $X(c d)$ is a random variable distributed according to an (unsymmetric) Poisson distribution with parameter $c d$, and $X(c d)$ is independent of the $u_{d}(k)$ 's and of the $v_{d^{\prime}}(k)$ 's. Thus by the previous theorem, with the notation $B\left(d, d^{\prime}\right)=N\left(d, d^{\prime}\right) N\left(d, d^{\prime}\right)^{*}$, the probability of the event

$$
\left\{\sup _{\Im z \geq 1}\left|\frac{1}{d} \operatorname{Tr} \Re_{z}\left(B\left(d, d^{\prime}\right)\right)-G_{\sigma}(z)\right|>\varepsilon\right\}
$$

tends to zero. Thus it suffices to prove that the probability of the event

$$
\left\{\sup _{\Im z \geq 1}\left|\frac{1}{d} \operatorname{Tr}\left(\Re_{z}\left(B\left(d, d^{\prime}\right)\right)-\Re_{z}\left(A\left(d, d^{\prime}, d^{\prime \prime}\right)\right)\right)\right|>\varepsilon\right\}
$$

tends to zero. But for all hermitian $d \times d$ matrices $A, B$, for all $z$ such that $\Im z \geq 1$, we have

$$
\mathfrak{R}_{z}(B)-\mathfrak{\Re}_{z}(A)=-\mathfrak{R}_{z}(B)(B-A) \mathfrak{R}_{z}(A),
$$

whose normalized trace is not more than its norm times its rank divided by $d$. Moreover, $\left\|\Re_{z}(B)-\Re_{z}(A)\right\| \leq 2$, and the rank is not more than the one of $B-A$. So it suffices to prove that

$$
\frac{1}{d} \operatorname{rg}\left(B\left(d, d^{\prime}\right)-A\left(d, d^{\prime}, d^{\prime \prime}\right)\right)
$$

converges in probability to zero. $B\left(d, d^{\prime}\right)-A\left(d, d^{\prime}, d^{\prime \prime}\right)$ can be puten in the form

$$
(\ldots)\left(N\left(d, d^{\prime}\right)-M\left(d, d^{\prime}, d^{\prime \prime}\right)\right)^{*}+\left(N\left(d, d^{\prime}\right)-M\left(d, d^{\prime}, d^{\prime \prime}\right)\right)(\ldots)
$$

so

$$
\frac{1}{d} \operatorname{rg}\left(B\left(d, d^{\prime}\right)-A\left(d, d^{\prime}, d^{\prime \prime}\right)\right) \leq \frac{2}{d} \operatorname{rg}\left(N\left(d, d^{\prime}\right)-M\left(d, d^{\prime}, d^{\prime \prime}\right)\right) \leq \frac{2}{d}\left|X(c d)-d^{\prime \prime}\right|
$$

which converges in probability to zero, by the weak law of great numbers.
