#### Abstract

. We study a two parameter version of the Hermite subdivision scheme introduced in [7], which gives $C^{1}$ interpolants on rectangular meshes. We prove $C^{1}$-convergence for a range of the two parameters. By introducing a control grid we can choose the parameters in the scheme so that the interpolant inherits positivity and/or directional monotonicity from the initial data. Several examples are given showing that a desired shape can be achieved even if we use only very crude estimates for the initial slopes.

Math Subject Classification: 65D05, 65D17
Keywords: Interpolation, Subdivision, Hermite Data, Rectangular Mesh, Positivity, Monotonicity.

## 1 Introduction

Subdivision is a technique for constructing smooth curves or surfaces out of a sequence of successive refinements of polygons, or grids see [3]. Subdivision has found applications in areas such as geometric design [10, 21], and in computer games and animation [6]. Subdivision schemes can be of Lagrange type or Hermite type. In this last case derivatives are also used. This can be desirable since a Hermite scheme can be made more local, making it easier to obtain a desired shape. Moreover, as our examples show, we can achieve a required shape using only very crude estimates for the derivatives. For some classical methods for bimonotone interpolation on a rectangular grid see $[1,2,4,5]$.

The first Hermite scheme was introduced in [15]. This method has smoothness $C^{1}$ and we refer to it as the $H C^{1}$-scheme. A notion of control points for two subfamilies of the $H C^{1}$-scheme were introduced in [18]. In [14] some further studies of the $H C^{1}$-scheme where carried out. The calculation of values and derivatives was separated and this made it possible to simplify some of the proofs in [17]. It was also shown that a geometric formulation of the scheme has a totally positive transformation matrix, and algorithms for constructing curves satisfying local positivity, monotonicity, and convexity constraints were given and tested. For more references to Hermite subdivision see [8, 9, 12, 13, 16, 22].
In $[11,19]$ Hermite subdivision was studied on a rectangular mesh using tensor products of the $H C^{1}$-scheme and its control points. An algorithm for achieving a bimonotone interpolant was given.

A disadvantage using the tensor product construction is that mixed partial derivatives $\partial^{2} f / \partial x \partial y$ is required as input data. In this paper we consider an alternative method the $H R C^{1}$-algorithm, where these mixed partial derivatives are not required. This scheme was introduced in [7]. It is a generalization of a $C^{1}$-quadratic finite element on a quadrilateral mesh ([20]). To describe the $H R C^{1}$-algorithm we start with values and gradients at the vertices of a rectangular grid $G$ in the plane. The algorithm is applied to each rectangle $R$ in turn by a local process. We divide $R$ into 4 rectangles by connecting midpoints of opposite edges and then compute values and derivatives at the vertices of the 4 sub-rectangles. Repeating this on each sub-rectangle we obtain in the limit a function defined on a dense subset of $R$. The scheme is interpolatory, i.e it retains the values at the vertices of the current rectangular grid. Moreover the value on an edge $E$ of $R$ only depends on the length of $E$ and on the values of $f$ and its derivatives at the endpoints of $E$. This makes it possible to obtain a global smooth surface by gluing together $H R C^{1}$-interpolants on neighboring sub-rectangles.
Our paper can be detailed as follows. In Section 2, we first recall the $H R C^{1}$ algorithm and some of its properties which were proved in [7]. We consider a simplified version of the scheme using only two parameters $\alpha$ and $\beta$. We show that this version simplifies further if we choose $\alpha=\beta /(4(1-\beta))$.

In Section 3 we show $C^{1}$-convergence of the $H R C^{1}$-algorithm for a range of the parameters $\alpha$ and $\beta$. This extends results in [7] where $C^{1}$-convergence was only shown for $\alpha=-1 / 8$. We also show Hölder continuity of the first order partial derivatives.
In Section 4 we define a control grid thereby giving a geometric formulation of the $H R C^{1}$-algorithm. This formulation is used in Section 5 to show how local shape constraints can be achieved in the limit function. We give several examples involving positivity and directional monotonicity constraints. We also show that a convexity preserving $H R C^{1}$-interpolant cannot be obtained in general.

## 2 Description of the algorithm $H R C^{1}$

We let $R:=[a, b] \times[c, d]$ be a given rectangle. The algorithm $H R C^{1}$ which gives a $C^{1}$ Hermite interpolant on $R$ was proposed by Dubuc and Merrien [7]. The goal is to construct a bivariate function $f$ and its first partial derivatives $p:=f_{x}, q:=f_{y}$ on $R$ in such a way that $f, p, q$ are continuous.

The $H R C^{1}$-Algorithm can be formulated as follows. We start with Hermite data $f_{i, j}^{0}, p_{i, j}^{0}, q_{i, j}^{0}$ for $i, j=0,1$ at the corners of the rectangle $\left[s_{0}^{0}, s_{1}^{0}\right] \times\left[t_{0}^{0}, t_{1}^{0}\right]:=$ $[a, b] \times[c, d]$. For $n=0,1,2, \ldots$, let us denote by $\mathcal{P}_{n}$ the regular partition of $[a, b]$ into $2^{n}$ subintervals and by $\mathcal{Q}_{n}$ the similar regular partition of $[c, d]$. Also let $\mathcal{P}:=\cup_{n \in \mathbb{N}} \mathcal{P}_{n}$ and $\mathcal{Q}:=\cup_{n \in \mathbb{N}} \mathcal{Q}_{n}$. For $n=0,1,2, \ldots$ the points in the partitions are denoted by $s_{i}^{n}:=a+i h_{n}$ and $t_{j}^{n}:=c+j k_{n}$, for $i, j=0, \ldots, 2^{n}$, where $h_{n}:=2^{-n}(b-a)$ and $k_{n}:=2^{-n}(d-c)$. What we compute at the grid points $\left(s_{i}^{n}, t_{j}^{n}\right)$ can be viewed either as point sequences $\left\{f_{i j}^{n}\right\},\left\{p_{i j}^{n}\right\},\left\{q_{i j}^{n}\right\}$ or as functions $f, p, q: \mathcal{P} \times \mathcal{Q} \rightarrow \mathbb{R}$ defined by $f\left(s_{i}^{n}, t_{j}^{n}\right):=f_{i j}^{n}, p\left(s_{i}^{n}, t_{j}^{n}\right):=p_{i j}^{n}$, and $q\left(s_{i}^{n}, t_{j}^{n}\right):=q_{i j}^{n}$. We will find both the sequence point of view and the function point of view useful.
To define $f, p$ and $q$ on $\mathcal{P} \times \mathcal{Q}$, we proceed by induction on $n$. For $n=0,1,2, \ldots$ suppose we have computed $\left\{f_{i, j}^{n}\right\},\left\{p_{i, j}^{n}\right\}$, and $\left\{q_{i, j}^{n}\right\}$ on the grid $\mathcal{P}_{n} \times \mathcal{Q}_{n}$. We set $h_{n}:=2^{-n}(b-a), k_{n}:=2^{-n}(d-c)$ and compute $f_{i, j}^{n+1}, p_{i, j}^{n+1}$, and $q_{i, j}^{n+1}$ on
the grid $\mathcal{P}_{n+1} \times \mathcal{Q}_{n+1}$ as follows:

$$
\begin{align*}
& \text { for } i=2^{n}:-1: 0, \text { for } j=2^{n}:-1: 0 \\
& \quad f_{2 i, 2 j}^{n+1}:=f_{i, j}^{n}, \quad p_{2 i, 2 j}^{n+1}:=p_{i, j}^{n}, \quad q_{2 i, 2 j}^{n+1}:=q_{i, j}^{n} \tag{2.1}
\end{align*}
$$

$$
\begin{align*}
& \text { for } i=0: 2^{n}-1, \quad \text { for } j=0: 2^{n} \\
& f_{2 i+1,2 j}^{n+1} \\
&:=\frac{f_{i+1, j}^{n}+f_{i, j}^{n}}{2}+\alpha h_{n}\left(p_{i+1, j}^{n}-p_{i, j}^{n}\right)  \tag{2.2}\\
& p_{2 i+1,2 j}^{n+1}:=(1-\beta) \frac{f_{i+1, j}^{n}-f_{i, j}^{n}}{h_{n}}+\beta \frac{p_{i+1, j}^{n}+p_{i, j}^{n}}{2}, \\
& q_{2 i+1,2 j}^{n+1}:=\frac{q_{i+1, j}^{n}+q_{i, j}^{n}}{2}
\end{align*}
$$

$$
\begin{aligned}
& \text { for } i=0: 2^{n}, \quad \text { for } j=0: 2^{n}-1 \\
& f_{2 i, 2 j+1}^{n+1}:=\frac{f_{i, j+1}^{n}+f_{i, j}^{n}}{2}+\alpha k_{n}\left(q_{i, j+1}^{n}-q_{i, j}^{n}\right), \\
& p_{2 i, 2 j+1}^{n+1}:=\frac{p_{i, j+1}^{n}+p_{i, j}^{n}}{2}, \\
& q_{2 i, 2 j+1}^{n+1}:=(1-\beta) \frac{f_{i, j+1}^{n}-f_{i, j}^{n}}{k_{n}}+\beta \frac{q_{i, j+1}^{n}+q_{i, j}^{n}}{2},
\end{aligned}
$$

$$
\begin{aligned}
\text { for } i=0: 2^{n}- & 1, \quad \text { for } j=0: 2^{n}-1 \\
f_{2 i+1,2 j+1}^{n+1}:= & \frac{f_{i, j}^{n}+f_{i+1, j}^{n}+f_{i, j+1}^{n}+f_{i+1, j+1}^{n}}{4} \\
& +\alpha h_{n} \frac{p_{i+1, j}^{n}-p_{i, j}^{n}+p_{i+1, j+1}^{n}-p_{i, j+1}^{n}}{2} \\
& +\alpha k_{n} \frac{q_{i, j+1}^{n}-q_{i, j}^{n}+q_{i+1, j+1}^{n}-q_{i+1, j}^{n}}{2} \\
p_{2 i+1,2 j+1}^{n+1}:= & (1-\beta) \frac{f_{i+1, j}^{n}-f_{i, j}^{n}+f_{i+1, j+1}^{n}-f_{i, j+1}^{n}}{2 h_{n}} \\
& +\beta \frac{p_{i, j}^{n}+p_{i, j+1}^{n}+p_{i+1, j}^{n}+p_{i+1, j+1}^{n}}{4} \\
& +\beta k_{n} \frac{q_{i+1, j+1}^{n}-q_{i+1, j}^{n}+q_{i, j}^{n}-q_{i, j+1}^{n}}{4 h_{n}}, \\
q_{2 i+1,2 j+1}^{n+1}:= & (1-\beta) \frac{f_{i, j+1}^{n}-f_{i, j}^{n}+f_{i+1, j+1}^{n}-f_{i+1, j}^{n}}{2 h_{n}} \\
& +\beta \frac{q_{i, j}^{n}+q_{i+1, j}^{n}+q_{i, j+1}^{n}+p_{i+1, j+1}^{n}}{4} \\
& +\beta k_{n} \frac{p_{i+1, j+1}^{n}-p_{i, j+1}^{n}+p_{i, j}^{n}-q_{i+1, j}^{n}}{4 h_{n}} .
\end{aligned}
$$

In (2.1) we simply redefine the functions at the points on $\mathcal{P}_{n} \times \mathcal{Q}_{n}$ as points on a subset of $\mathcal{P}_{n+1} \times \mathcal{Q}_{n+1}$. These points are marked by gray squares in Figure 2.1. In (2.3-2.4) we compute new values at the new points marked by black circles in Figure 2.1.

Figure 2.1: Recursive computation of $f, p$ and $q$.
For $\alpha=-1 / 8, \beta=-1$ it was shown in [7] that we obtain the Sibson-Thomson interpolant on $R$ proposed in [20]. In this case, the $H R C^{1}$-interpolant is a $C^{1}$ piecewise quadratic consisting of 16 individual pieces, see Figure 2.2. Moreover the cross boundary derivatives are linear functions along the outer boundary of $[a, b] \times[c, d]$.
It was shown in [7] that the $H R C^{1}$-algorithm is exact for bilinear functions for any value of $\alpha$ and $\beta$. It is exact for quadratic polynomials if and only if $\alpha=-1 / 8$ and exact for cubic polynomials if and only if $\alpha=-1 / 8$ and $\beta=-1 / 2$.

Figure 2.2: Sibson-Thomson subdivision of a rectangle.
We have simplified the construction of [7] and it depends on only two parameters $\alpha$ and $\beta$. This simplification gives new formulas for the computation of $f_{2 i+1,2 j+1}^{n+1}, p_{2 i+1,2 j+1}^{n+1}$ and $q_{2 i+1,2 j+1}^{n+1}$.

Proposition 2.1
(2.5)

$$
\begin{aligned}
& \text { for } i=0: 2^{n}-1, \quad \text { for } j=0: 2^{n}-1 \\
& f_{2 i+1,2 j+1}^{n+1}= \frac{f_{2 i+2,2 j+1}^{n+1}+f_{2 i, 2 j+1}^{n+1}}{2}+\alpha h_{n}\left(p_{2 i+2,2 j+1}^{n+1}-p_{2 i, 2 j+1}^{n+1}\right), \\
&= \frac{f_{2 i+1,2 j+2}^{n+1}+f_{2 i+1,2 j}^{n+1}}{2}+\alpha k_{n}\left(q_{2 i+1,2 j+2}^{n+1}-q_{2 i+1,2 j}^{n+1}\right), \\
& p_{2 i+1,2 j+1}^{n+1}=(1-\beta) \frac{f_{2 i+2,2 j+1}^{n+1}-f_{2 i, 2 j+1}^{n+1}}{h_{n}}+\beta \frac{p_{2 i+2,2 j+1}^{n+1}+p_{2 i, 2 j+1}^{n+1}}{2} \\
&+\frac{k_{n}}{h_{n}}((1-\beta) \alpha-\beta / 4)\left(q_{2 i+2,2 j}^{n+1}-q_{2 i+2,2 j+2}^{n+1}+q_{2 i, 2 j+2}^{n+1}-q_{2 i, 2 j}^{n+1}\right), \\
& q_{2 i+1,2 j+1}^{n+1}=(1-\beta) \frac{f_{2 i+1,2 j+2}^{n+1}-f_{2 i+1,2 j}^{n+1}}{k_{n}}+\beta \frac{q_{2 i+1,2 j+2}^{n+1}+q_{2 i+1,2 j}^{n+1}}{2} \\
&+\frac{h_{n}}{k_{n}}((1-\beta) \alpha-\beta / 4)\left(p_{2 i, 2 j+2}^{n+1}-p_{2 i+2,2 j+2}^{n+1}+p_{2 i+2,2 j}^{n+1}-p_{2 i, 2 j}^{n+1}\right) .
\end{aligned}
$$

Proof. For $n \in \mathbb{N}, i, j \in\left\{0, \ldots, 2^{n}-1\right\}$, the first formula of (2.4) can be written:

$$
\begin{aligned}
f_{2 i+1,2 j+1}^{n+1}= & \frac{1}{2}\left[\frac{f_{i+1, j+1}^{n}+f_{i+1, j}^{n}}{2}+\alpha k_{n}\left(q_{i+1, j+1}^{n}-q_{i+1, j}^{n}\right)\right. \\
& \left.+\frac{\left.f_{i, j+1}^{n}+f_{i, j}^{n}\right)}{2}+\alpha k_{n}\left(q_{i, j+1}^{n}-q_{i, j}^{n}\right)\right] \\
& +\alpha h_{n}\left[\frac{p_{i+1, j+1}^{n}+p_{i+1, j}^{n}}{2}-\frac{p_{i, j+1}^{n}+p_{i, j}^{n}}{2}\right] .
\end{aligned}
$$

Using (2.3) this gives the first formula in (2.5). The proof of the second formula is similar.
We write the second formula of (2.4)

$$
\begin{aligned}
p_{2 i+1,2 j+1}^{n+1} & =\frac{1-\beta}{h_{n}}\left[\frac{f_{i+1, j+1}^{n}+f_{i+1, j}^{n}}{2}+\alpha k_{n}\left(q_{i+1, j+1}^{n}-q_{i+1, j}^{n}\right)\right] \\
& -\frac{1-\beta}{h_{n}}\left[\frac{f_{i, j+1}^{n}+f_{i, j}^{n}}{2}+\alpha k_{n}\left(q_{i, j+1}^{n}-q_{i, j}^{n}\right)\right] \\
& +\frac{\beta}{2}\left[\frac{p_{i+1, j+1}^{n}+p_{i+1, j}^{n}}{2}+\frac{p_{i, j+1}^{n}+p_{i, j}^{n}}{2}\right] \\
& +\frac{k_{n}}{h_{n}}[(1-\beta) \alpha-\beta / 4]\left[q_{i+1, j}^{n}-q_{i+1, j+1}^{n}+q_{i, j+1}^{n}-q_{i, j}^{n}\right] .
\end{aligned}
$$

Thanks to (2.1) and (2.3), we obtain the result. The last formula is symmetrical from the previous one.

## $3 C^{1}$-convergence of the algorithm

We say that the scheme is $C^{1}$-convergent if, for any initial data, the functions $f, p$, and $q$ can be extended from $\mathcal{P} \times \mathcal{Q}$ to continuous functions on $[a, b] \times[c, d]$
with $p=f_{x}$ and $q=f_{y}$. We call $f$ defined either on $\mathcal{P} \times \mathcal{Q}$ or on $[a, b] \times[c, d]$ the $H R C^{1}$-interpolant to the data.
For the study of $C^{1}$-convergence it is enough to consider the construction on the unit square $[0,1]^{2}$. To see this, let $h=b-a, k=d-c$ and let again $(a, c)$ be the south-west vertex of the initial rectangle $[a, b] \times[c, d]$. On $[0,1]^{2}$, we define the initial data $g(u, v):=f(a+u h, c+v k), g_{x}(u, v):=h f_{x}(a+u h, c+v k)$, $g_{y}(u, v):=k f_{y}(a+u h, c+v k),(u, v) \in\{0,1\}^{2}$. The constructions of $f$ or $g$ by formulas (2.1), (2.2), (2.3) and (2.4) are equivalent and at each step, we obtain $g(u, v)=f(a+u h, c+v k), g_{x}(u, v)=h f_{x}(a+u h, c+v k)$ and $g_{y}(u, v)=$ $k f_{y}(a+u h, c+v k),(u, v) \in\left\{0,1 / 2^{n}, \ldots, \ell / 2^{n}, \ldots, 1\right\}^{2}$. Thus the $C^{1}$-convergence of $f$ on $[a, b] \times[c, d]$ is equivalent to the $C^{1}$-convergence of $g$ on $[0,1]^{2}$.
So let us begin with data on the vertices of the unit square $[0,1]^{2}$. For $n \geq 0$ and $i, j=0,1, \ldots, 2^{n}-1$ we define vectors of differences $U_{i j}^{n} \in \mathbb{R}^{12}$ as follows:

We then have
Lemma 3.1. Suppose we can find a vector norm $\|\cdot\|$ on $\mathbb{R}^{12}$ and positive constants $c, \rho$ with $\rho<1$ such that

$$
\left\|U_{i j}^{n}\right\| \leq c \rho^{n}, \text { for } i, j=0, \ldots, 2^{n}-1
$$

Then the $H R C^{1}$-algorithm is $C^{1}$-convergent.
Proof. The proof of the $C^{1}$-convergence on $[0,1]^{2}$ is detailed in [7]. To summarize, with the hypothesis, it can be proved that $p$ and $q$ are uniformly continuous on the dyadic points so that they can be extended into continuous functions on $[0,1]^{2}$. Then we extend $f$ and prove that $f_{x}=p$ and $f_{y}=q$ using the four last components of $U_{i, j}^{n}$.

To bound the vectors $U_{i j}^{n}$ we will use the following recurrence relations.
Proposition 3.2. We have

$$
\begin{aligned}
U_{i j}^{n+1} & =\Lambda^{(1)} U_{i j}^{n}, U_{i+1, j}^{n+1}=\Lambda^{(2)} U_{i j}^{n}, \\
U_{i+1, j+1}^{n+1} & =\Lambda^{(3)} U_{i j}^{n}, U_{i, j+1}^{n+1}=\Lambda^{(4)} U_{i j}^{n},
\end{aligned}
$$

where $\Lambda^{(1)}, \Lambda^{(2)}, \Lambda^{(3)}, \Lambda^{(4)}$ are 4 matrices in $\mathbb{R}^{12 \times 12}$ depending only on the 2 parameters $\alpha, \beta$ of algorithm $H R C^{1}$. Explicit formulas for the matrices are as
follows:

$$
\Lambda^{(i)}=\left[\begin{array}{ccc}
\Lambda_{11}^{(i)} & \Lambda_{12}^{(i)} & \Lambda_{13}^{(i)} \\
0 & \Lambda_{22}^{(i)} & \Lambda_{23}^{(i)} \\
0 & \Lambda_{32}^{(i)} & \Lambda_{33}^{(i)}
\end{array}\right]=\left[\begin{array}{cc}
\Lambda_{11}^{(i)} & \ldots \\
0 & M^{(i)}
\end{array}\right]
$$

with $\Lambda_{j k}^{(i)} \in \mathbb{R}^{4 \times 4}$ and $M^{(i)} \in \mathbb{R}^{8 \times 8}$. More specifically:

$$
\begin{aligned}
& \Lambda_{11}^{(1)}=\left[\begin{array}{cccc}
\frac{1}{2} & 0 & 0 & 0 \\
0 & \frac{1}{4} & 0 & \frac{1}{4} \\
\frac{1}{4} & 0 & \frac{1}{4} & 0 \\
0 & 0 & 0 & \frac{1}{2}
\end{array}\right], \Lambda_{11}^{(2)}=\left[\begin{array}{cccc}
\frac{1}{2} & 0 & 0 & 0 \\
0 & \frac{1}{2} & 0 & 0 \\
\frac{1}{4} & 0 & \frac{1}{4} & 0 \\
0 & \frac{1}{4} & 0 & \frac{1}{4}
\end{array}\right], \\
& \Lambda_{11}^{(3)}=\left[\begin{array}{cccc}
\frac{1}{4} & 0 & \frac{1}{4} & 0 \\
0 & \frac{1}{2} & 0 & 0 \\
0 & 0 & \frac{1}{2} & 0 \\
0 & \frac{1}{4} & 0 & \frac{1}{4}
\end{array}\right], \Lambda_{11}^{(4)}=\left[\begin{array}{cccc}
\frac{1}{4} & 0 & \frac{1}{4} & 0 \\
0 & \frac{1}{4} & 0 & \frac{1}{4} \\
0 & 0 & \frac{1}{2} & 0 \\
0 & 0 & 0 & \frac{1}{2}
\end{array}\right] \text {, } \\
& \left(\Lambda_{12}^{(1)} \Lambda_{13}^{(1)}\right)=\left[\begin{array}{cccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & \beta / 4 & 0 & -\beta / 4 & \frac{\beta-1}{2} & 0 & \frac{1-\beta}{2} & 0 \\

$$

Proof. These relations were shown in [7] using a a computer algebra system.
We will not need the explicit form of the matrices $\left[\Lambda_{12}^{(i)} \Lambda_{13}^{(i)}\right]$ for $i \in\{1,2,3,4\}$. One can obtain all of them from $\left[\Lambda_{12}^{(1)} \Lambda_{13}^{(1)}\right]$ by permutations of rows and columns.
We mention that in [7] it was proved that the scheme is $C^{1}$-convergent if and only if the generalized spectral radius of $\Sigma=\left\{\Lambda^{(1)}, \Lambda^{(2)}, \Lambda^{(3)}, \Lambda^{(4)}\right\}$ satisfies $\hat{\rho}(\Sigma)<1$. The following analysis is maybe somewhat simpler. We start with a proposition.

Proposition 3.3. If there exists a vector norm $\|\cdot\|$ on $\mathbb{R}^{12}$ and a number $\rho<1$ such that the associated matrix operator norm satisfies $\left\|\Lambda^{(i)}\right\| \leq \rho$ for $i=1,2,3,4$ then the scheme is $C^{1}$-convergent. Moreover the functions $p$ and $q$ are Hölder continuous with exponent $-\log _{2}(\rho)$.
Proof. It is enough to prove the Proposition on the square $[0,1]^{2}$. That the scheme is $C^{1}$-convergent follows immediately from Lemma 3.1.

The proof that $p$ and $q$ are Hölder continuous is similar to a proof in dimension one in [17]. In the following proof we will use the function notation for the sequences $\left\{U_{i j}^{n}\right\}_{i, j},\left\{f_{i j}^{n}\right\}_{i, j},\left\{p_{i j}^{n}\right\}_{i, j}$, and $\left\{q_{i j}^{n}\right\}_{i, j}$. Thus if $x:=i 2^{-n}$ and $y:=$ $j 2^{-n}$ then we write $U_{i j}^{n}$ and $p_{i j}^{n}$ as $U^{n}(x, y)$ and $p^{n}(x, y)$. We recall that $\mathcal{P}_{\ell}=$ $\left\{k 2^{-\ell}, k=0, \ldots, 2^{\ell}\right\}, \ell \in \mathbb{N}$ is the set of dyadic points at step $\ell$ on $[0,1]$ and we write $h_{\ell}=1 / 2^{\ell}$. With the hypothesis, for $(x, y) \in \mathcal{P}_{\ell}{ }^{2}, x \neq 1, y \neq 1$, we have $\left\|U^{\ell}(x, y)\right\| \leq \rho^{\ell}\left\|U^{0}(0,0)\right\|$ for $\ell \geq 0$. Using the equivalence of the norms in $\mathbb{R}^{12}$, this implies that $\left\|U^{\ell}(x, y)\right\|_{\infty} \leq c_{2} \rho^{\ell}$ for some positive constant $c_{2}$ independent of $U^{\ell}$. In particular, this holds for components 4 and 5 of $U^{\ell}(x, y)$ and we deduce that

$$
\begin{align*}
& \left|p\left(x \pm h_{\ell}, y\right)-p(x, y)\right| \leq c_{2} \rho^{\ell}, \text { with }(x, y),\left(x \pm h_{\ell}, y\right) \in \mathcal{P}_{\ell}{ }^{2} \\
& \left|p\left(x, y \pm h_{\ell}\right)-p(x, y)\right| \leq c_{2} \rho^{\ell}, \text { with }(x, y),\left(x, y \pm h_{\ell}\right) \in \mathcal{P}_{\ell}{ }^{2} \tag{3.1}
\end{align*}
$$

Suppose that $P_{1}=\left(x_{1}, y_{1}\right)$ and $P_{2}=\left(x_{2}, y_{2}\right)$ are 2 points in $[0,1]^{2}$. Let $n$ be the unique nonnegative integer such that $2^{-n-1}<\left\|P_{1}-P_{2}\right\|_{\infty} \leq 2^{-n}$. Then $\left|x_{2}-x_{1}\right| \leq 2^{-n}$ and $\left|y_{2}-y_{1}\right| \leq 2^{-n}$ and there exist $x, y \in \mathcal{P}_{n}$ such that $\left|x_{j}-x\right| \leq 2^{-n}$ and $\left|y_{j}-y\right| \leq 2^{-n}$ for $j=1,2$. Thus $P:=(x, y) \in \mathcal{P}_{n}{ }^{2}$ is such that $\left\|P_{j}-P\right\|_{\infty} \leq 2^{-n}$ for $j=1,2$.
To prove that $\left|p\left(P_{1}\right)-p(P)\right| \leq c_{3} \rho^{n}$ for some constant $c_{3}$ we write $P_{1}=$ $P+\sum_{i=1}^{\infty}\left(u_{i}, v_{i}\right) 2^{-i-n}$ with $u_{i}$ and $v_{i}$ in $\{0,1,-1\}$. We define the sequence $\left\{\hat{P}_{j}\right\}:=\left\{\left(\hat{x}_{j}, \hat{y}_{j}\right)\right\}$ by $\hat{P}_{0}=P$ and $\hat{P}_{j}=\hat{P}_{j-1}+\left(u_{j}, v_{j}\right) 2^{-j-n}$, for $j \geq 1$. Then $\hat{P}_{j} \in \mathcal{P}_{n+j}{ }^{2}$ and

$$
\left|p\left(\hat{P}_{j}\right)-p\left(\hat{P}_{j-1}\right)\right| \leq\left|p\left(\hat{x}_{j}, \hat{y}_{j}\right)-p\left(\hat{x}_{j}, \hat{y}_{j-1}\right)\right|+\left|p\left(\hat{x}_{j}, \hat{y}_{j-1}\right)-p\left(\hat{x}_{j-1}, y_{j-1}\right)\right| .
$$

Since $\left(\hat{x}_{j}, \hat{y}_{j}\right),\left(\hat{x}_{j}, \hat{y}_{j-1}\right)$ and $\left(\hat{x}_{j-1}, \hat{y}_{j-1}\right)$ are in $\mathcal{P}_{n+j}{ }^{2}$ we can bound them using (3.1) with $\ell=n+j$ and we obtain $\left|p\left(\hat{P}_{j}\right)-p\left(\hat{P}_{j-1}\right)\right| \leq 2 c_{2} \rho^{n+j}$ so that $\mid p\left(P_{1}\right)-$ $p(P) \left\lvert\, \leq \sum_{j=1}^{\infty} 2 c_{2} \rho^{n+j}=\frac{2 c_{2}}{1-\rho} \rho^{n+1}\right.$.

With the same upper bound for $\left|p\left(P_{2}\right)-p(P)\right|$, we deduce that $\left|p\left(P_{2}\right)-p\left(P_{1}\right)\right| \leq$ $c_{4} \rho^{n+1}$ with $c_{4}=\frac{4 c_{2}}{1-\rho}$.
To conclude, notice that since $\left\|P_{1}-P_{2}\right\|_{\infty}>2^{-n-1}$ then

$$
\left|p\left(P_{2}\right)-p\left(P_{1}\right)\right| \leq c_{4} \rho^{n+1}=c_{4} 2^{(-n-1)\left(-\log _{2} \rho\right)}<c_{4}\left\|P_{1}-P_{2}\right\|_{\infty}^{-\log _{2}(\rho)}
$$

A similar inequality holds for the function $q$.
To find a good norm on $\mathbb{R}^{12}$, we use the following well known result:
Lemma 3.4. Corresponding to a positive integer $d$, a nonsingular matrix $P \in \mathbb{R}^{d \times d}$ and a vector norm $\|\cdot\|$ on $\mathbb{R}^{d}$ we define a vector norm on $\mathbb{R}^{d}$ by $\|V\|_{1}:=\left\|P^{-1} V\right\|$. Then the associated matrix operator norm $\|\cdot\|$ is given by $\|A\|_{1}=\left\|P^{-1} A P\right\|$ for any matrix $A \in \mathbb{R}^{d \times d}$.
Proof. Clearly $\|\cdot\|_{1}$ defines a norm on $\mathbb{R}^{d}$. Now if $A \in \mathbb{R}^{d \times d}$ then

$$
\|A\|_{1}:=\max _{V \neq 0} \frac{\|A V\|_{1}}{\|V\|_{1}}=\max _{V \neq 0} \frac{\left\|P^{-1} A V\right\|}{\left\|P^{-1} V\right\|}=\max _{U \neq 0} \frac{\left\|P^{-1} A P U\right\|}{\|U\|}=\left\|P^{-1} A P\right\|
$$

Let $\|\cdot\|_{1}$ and $\|\cdot\|_{2}$ be two vector norms on $\mathbb{R}^{d_{1}}$ and $\mathbb{R}^{d_{2}}$ respectively. For a matrix $A \in \mathbb{R}^{d_{1} \times d_{2}}$ we write $\|A\|_{12}$ for the associated mixed matrix operator norm $\|A\|_{12}:=\max _{V \in \mathbb{R}^{d_{2}, V \neq 0}} \frac{\|A V\|_{1}}{\|V\|_{2}}$.
Lemma 3.5. Suppose for positive integers $d_{1}$ and $d_{2}$ that $\Sigma$ is a set of square matrices $\{A\}$ of order $d:=d_{1}+d_{2}$ that are written by blocks as

$$
A=\left[\begin{array}{ll}
A_{11} & A_{12}  \tag{3.2}\\
A_{21} & A_{22}
\end{array}\right]
$$

with diagonal blocks $A_{i i} \in \mathbb{R}^{d_{i} \times d_{i}}$ for $i=1,2$. For $i=1,2$, let $\|\cdot\|_{i}$ be two vector norms on $\mathbb{R}^{d_{i}}$ and for $i, j=1,2$, let $\gamma_{i j}$ be positive constants such that for any $A \in \Sigma$ the estimates $\left\|A_{i j}\right\|_{i j} \leq \gamma_{i j}$ hold. If

$$
\gamma_{11}<1, \quad \gamma_{22}<1, \text { and } \gamma_{21} \gamma_{12}<\left(1-\gamma_{11}\right)\left(1-\gamma_{22}\right)
$$

then we can find a matrix norm on $\mathbb{R}^{d \times d}$ such that any $A \in \Sigma$ has norm less than 1.

Proof. On $\mathbb{R}^{d}$, we define a norm $\|\cdot\|_{\theta}$ depending on a parameter $\theta>0$. If $V=(X, Y)^{T}$ with $X \in \mathbb{R}^{d_{1}}$ and $Y \in \mathbb{R}^{d_{2}}$ then $\|V\|_{\theta}:=\|X\|_{1}+\theta\|Y\|_{2}$.
Then for any matrix $A \in \mathbb{R}^{d \times d}$, we have:

$$
\begin{aligned}
\|A V\|_{\theta} & =\left\|A_{11} X+A_{12} Y\right\|_{1}+\theta\left\|A_{21} X+A_{22} Y\right\|_{2} \\
& \leq\left\|A_{11}\right\|_{11}\|X\|_{1}+\left\|A_{12}\right\|_{12}\|Y\|_{2}+\theta\left\|A_{21}\right\|_{21}\|X\|_{1}+\theta\left\|A_{22}\right\|_{22}\|Y\|_{2} \\
& =\left(\left\|A_{11}\right\|_{11}+\theta\left\|A_{21}\right\|_{21}\right)\|X\|_{1}+\left(\left\|A_{12}\right\|_{12} / \theta+\left\|A_{22}\right\|_{22}\right)\left(\theta\|Y\|_{2}\right) \\
& \leq \max \left(\left\|A_{11}\right\|_{11}+\theta\left\|A_{21}\right\|_{21},\left\|A_{12}\right\|_{12} / \theta+\left\|A_{22}\right\|_{22}\right)\|V\|_{\theta} .
\end{aligned}
$$

We deduce that

$$
\begin{equation*}
\|A\|_{\theta} \leq \max \left(\left\|A_{11}\right\|_{11}+\theta\left\|A_{21}\right\|_{21},\left\|A_{12}\right\|_{12} / \theta+\left\|A_{22}\right\|_{22}\right), A \in \mathbb{R}^{d \times d} \tag{3.3}
\end{equation*}
$$

$\|A\|_{\theta}<1$, as soon as $\left\|A_{11}\right\|_{11}+\theta\left\|A_{21}\right\|_{21}<1$ and $\left\|A_{12}\right\|_{12} / \theta+\left\|A_{22}\right\|_{22}<1$. Since, for any $A \in \Sigma,\left\|A_{i j}\right\| \leq \gamma_{i j}, i, j=1,2$, it suffices that $\gamma_{11}+\theta \gamma_{21}<1$ and $\gamma_{12} / \theta+\gamma_{22}<1$. If $\gamma_{11}<1$ and $\gamma_{22}<1$, these conditions are satisfied whenever there exists a real number $\theta>0$ such that $\frac{\gamma_{12}}{1-\gamma_{22}}<\theta<\frac{1-\gamma_{11}}{\gamma_{21}}$. Since $\gamma_{21} \gamma_{12}<\left(1-\gamma_{11}\right)\left(1-\gamma_{22}\right)$ we can find such a $\theta$.
Lemma 3.6. Suppose in Lemma 3.5 that $\Sigma$ is a finite family of matrices of the form (3.2) with $A_{21}=0$. If there exists a real number $c>0$ such that for any $A \in \Sigma,\left\|A_{11}\right\|_{11} \leq c$ and $\left\|A_{22}\right\|_{22}<c$ then there exists a matrix norm such that for all $A \in \Sigma$, we have $\|A\| \leq c$.
Proof. Using (3.3) in the previous Lemma, $\|A\|_{\theta} \leq \max \left(\left\|A_{11}\right\|_{11},\left\|A_{12}\right\|_{12} / \theta+\right.$ $\left.\left\|A_{22}\right\|_{22}\right)$. Now $\| A_{11} \leq c$ and $\left\|A_{22}\right\|_{22}<c$. Since the set $\Sigma$ is finite, we can find a real number $\theta>0$ such that for any $A \in \Sigma,\left\|A_{12}\right\|_{12} / \theta$ is small enough to get $\|A\|_{\theta} \leq c$.
Now we have the tools to study the $C^{1}$-convergence of the algorithm.

Figure 3.1: The region $\mathcal{R}$ in Theorem 3.7 together with the curve $\alpha=\beta /(4(1-\beta))$.
THEOREM 3.7. The algorithm $H R C^{1}$ is $C^{1}$ convergent if $(\alpha, \beta)$ belongs to the region

$$
\begin{equation*}
\mathcal{R}:=\left\{(\alpha, \beta):-\frac{1}{4}<\alpha<0 \text { and } l(\alpha)<\beta<u(\alpha)\right\} \tag{3.4}
\end{equation*}
$$

where

$$
\begin{align*}
& l(\alpha):= \begin{cases}8 \alpha-2+\sqrt{(8 \alpha+1)(8 \alpha-7)} & \text { if }-\frac{1}{4} \leq \alpha<-\frac{1}{6}, \\
-\frac{5}{3} & \text { if }-\frac{1}{6} \leq \alpha<-\frac{1}{8}, \\
\frac{2 \alpha-1}{2 \alpha+1} & \text { if }-\frac{1}{8} \leq \alpha \leq 0,\end{cases}  \tag{3.5}\\
& u(\alpha):= \begin{cases}16 \alpha+3, & \text { if }-\frac{1}{4} \leq \alpha<-\frac{1}{8}, \\
1 & \text { if }-\frac{1}{8} \leq \alpha \leq 0,\end{cases}
\end{align*}
$$

Proof. Let $\|A\|_{\infty}=\max _{i=1, \ldots, d}\left(\sum_{j=1}^{d}\left|a_{i j}\right|\right)$ be the matrix norm on $\mathbb{R}^{d \times d}$ associated with the vector norm $\|V\|_{\infty}=\max _{k=1, \ldots, d}\left(\left|v_{k}\right|\right)$ on $\mathbb{R}^{d}$. By Lemma 3.6, since $\left\|\Lambda_{11}^{(\ell)}\right\|_{\infty}=1 / 2$, with we get a matrix norm such that $\left\|\Lambda^{(\ell)}\right\|<1$ as soon as there exists a matrix norm such that $\left\|M^{(\ell)}\right\|<1, \ell=1, \ldots, 4$.
Let $P_{1}=\left[\begin{array}{cccc}1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1\end{array}\right]$ and $P=\left[\begin{array}{cc}P_{1} & 0 \\ 0 & P_{1}\end{array}\right]$. We compute
$N^{(\ell)}:=P^{-1} M^{(\ell)} P=\left[\begin{array}{ll}N_{11}^{(\ell)} & N_{12}^{(\ell)} \\ N_{21}^{(\ell)} & N_{22}^{(\ell)}\end{array}\right]$ for $\ell=1, \ldots, 4$. By Lemma 3.4 we know that it suffices to find a matrix norm such that $\left\|N^{(\ell)}\right\|<1$, for $\ell=1,2,3,4$. The computation gives:

$$
\begin{aligned}
& \left.N_{11}^{(1)}=\frac{1}{4}\left[\begin{array}{cccc}
2 & 0 & 1 & \beta \\
0 & 2 & -\beta & -1 \\
0 & 0 & 1 & -\beta \\
0 & 0 & -\beta & 1
\end{array}\right] \quad \begin{array}{cc} 
\\

0 & -1 / 4-2 \alpha & -\alpha+\beta / 8 & 1 / 8+\alpha \\
0 & 0 & 1 / 8+\alpha & \alpha-\beta / 8 \\
0 & 0 & -\alpha+\beta / 8 & -1 / 8-\alpha
\end{array}\right] \quad N_{12}^{(4)}=\frac{1-\beta}{2}\left[\begin{array}{cccc}
2 & 0 & -1 & 0 \\
0 & -2 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1
\end{array}\right]
\end{array}
\end{aligned}
$$

In $\mathbb{R}^{4}$, we use the norm $\|\cdot\|_{\theta}, \theta>0$ defined at the beginning of the proof of Lemma 3.5, using $\|\cdot\|_{\infty}$ in $\mathbb{R}^{4}$, i.e $\|U\|_{\theta}=\|X\|_{\infty}+\theta\|Y\|_{\infty}$ where $U=$
$\left[\begin{array}{l}X \\ Y\end{array}\right], X, Y \in \mathbb{R}^{2}$. Using (3.3), we deduce that for $A=\left[\begin{array}{cc}A_{11} & A_{12} \\ 0 & A_{22}\end{array}\right] \in \mathbb{R}^{4 \times 4}$ with $A_{i j} \in \mathbb{R}^{2 \times 2}$, we have $\|A\|_{\theta} \leq \max \left(\left\|A_{11}\right\|_{\infty},\left\|A_{12}\right\|_{\infty} / \theta+\left\|A_{22}\right\|_{\infty}\right)$.
For $\ell=1,2,3,4$, we can then bound $\left\|N_{i j}^{(\ell)}\right\|_{\theta}$. Let $\mu:=1+\frac{1}{\theta}>1$ and assume $\mu<2$. Then
$\left\|N_{11}^{(\ell)}\right\|_{\theta} \leq \frac{1}{4} \max (2, \mu(1-\beta))=: \gamma_{11}$,
$\left\|N_{12}^{(\ell)}\right\|_{\theta} \leq|1-\beta|=: \gamma_{12}$,
$\left\|N_{21}^{(\ell)}\right\|_{\theta} \leq \max (|1 / 4+2 \alpha|, \mu(|-\alpha+\beta / 8|+|1 / 8+\alpha|))=: \gamma_{21}$,
$\left\|N_{22}^{(\ell)}\right\|_{\theta} \leq \frac{|1+\beta|}{2}=: \gamma_{22}$.

Figure 3.2: The subsets $R_{1}, \ldots, R_{6}$ used in the proof of Theorem 3.7.
We need to bound the $\gamma^{\prime}$ s. The analysis below shows that it is enough to consider $(\alpha, \beta)$ in the rectangle $\left[-\frac{1}{4}, 0\right] \times[-2,1]$. To compute $\gamma_{21}$, which is the most difficult, we divide the rectangle $\left[-\frac{1}{4}, 0\right] \times[-2,1]$ into open subsets $R_{1}, \ldots, R_{6}$ as shown in Figure 3.2. In these regions a lengthy, but straightforward calculation gives the following values for the numbers $\gamma_{i j}$ and the quantity $\pi_{\gamma}:=$ $\left(1-\gamma_{11}\right)\left(1-\gamma_{22}\right)$ :

|  | $R_{1}$ | $R_{2}$ | $R_{3}$ | $R_{4}$ | $R_{5}$ | $R_{6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\gamma_{11}$ | $\frac{1}{2}$ | $\frac{1}{2}$ | $\frac{1}{2}$ | $\frac{\mu}{4}(1-\beta)$ | $\frac{\mu}{4}(1-\beta)$ | $\frac{\mu}{4}(1-\beta)$ |
| $\gamma_{22}$ | $\frac{1}{2}(1+\beta)$ | $\frac{1}{2}(1+\beta)$ | $\frac{1}{2}(1+\beta)$ | $-\frac{1}{2}(1+\beta)$ | $-\frac{1}{2}(1+\beta)$ | $-\frac{1}{2}(1+\beta)$ |
| $\gamma_{12}$ | $1-\beta$ | $1-\beta$ | $1-\beta$ | $1-\beta$ | $1-\beta$ | $1-\beta$ |
| $\gamma_{21}$ | $-\mu\left(2 \alpha+\frac{1-\beta}{8}\right)$ | $\frac{\mu}{8}(1+\beta)$ | $2 \alpha+\frac{1}{4}$ | $-2 \alpha-\frac{1}{4}$ | $-\frac{\mu}{8}(1+\beta)$ | $\mu\left(2 \alpha+\frac{1-\beta}{8}\right)$ |
| $\pi_{\gamma}$ | $\frac{1}{4}(1-\beta)$ | $\frac{1}{4}(1-\beta)$ | $\frac{1}{4}(1-\beta)$ | $\nu$ | $\nu$ | $\nu$ |

where $\nu:=\frac{1}{8}(3+\beta)^{2}-\epsilon$, and where $\epsilon>0$ can be made arbitrary small by choosing $\theta$ sufficiently big.
We need to compute subsets $S_{j}$ of $R_{j}$ so that $\gamma_{12} \gamma_{21}<\pi_{\gamma}$ for $(\alpha, \beta) \in S_{j}$, $j=1, \ldots, 6$.

- On $R_{1}$, we need $-\mu(1-\beta)\left(2 \alpha+\frac{1-\beta}{8}\right)<\frac{1-\beta}{4}$. This is satisfied if $\beta<16 \alpha+3$.
- On $R_{2}$, the condition is $\mu(1-\beta) \frac{1+\beta}{8}<\frac{1-\beta}{4}$ which holds if $\beta<1$.
- On $R_{3}$, we should have $(1-\beta)\left(\frac{1}{4}+2 \alpha\right)<\frac{1-\beta}{4}$. This is true for $\alpha<0$.
- On $R_{4}$, the inequality is $(1-\beta)\left(-\frac{1}{4}-2 \alpha\right)<\frac{(3+\beta)^{2}}{8}-\epsilon$. Since this should hold for all $\epsilon>0$ we can drop the $\epsilon$ (this is also true for $R_{5}$, and $R_{6}$ ) and we obtain

$$
\alpha<\frac{11+4 \beta+\beta^{2}}{16(1-\beta)} \text { or } \beta<8 \alpha-2+\sqrt{(8 \alpha+1)(8 \alpha-7)} .
$$

- The condition on $R_{5}$ takes the form $(1-\beta) \frac{1+\beta}{8}<\frac{(3+\beta)^{2}}{8}$ which holds if $\beta>-\frac{5}{3}$.
- Finally on $R_{6}$, the inequality $\mu(1-\beta)\left(2 \alpha+\frac{1-\beta}{8}\right)<\frac{(3+\beta)^{2}}{8}$ is true for $\beta<\frac{2 \alpha-1}{2 \alpha+1}$.
This defines the subregions $S_{j}$ of $R_{j}$ for $j=1, \ldots, 6$. It remains to show that the result also holds on the curve segments forming the interior boundaries between the regions. These curves can be identified as $\beta=-1, \alpha=-1 / 8$, and $\beta=16 \alpha+1$. We divide these curves into segments as follows:

$$
\begin{array}{ll}
C_{11}:=\left\{(\alpha, \beta):-\frac{1}{4}<\alpha<\frac{1}{8}, \beta=-1\right\}, & C_{12}:=\left\{(\alpha, \beta):-\frac{1}{8} \leq \alpha<0, \beta=-1\right\}, \\
C_{21}:=\left\{(\alpha, \beta): \alpha=-\frac{1}{8},-\frac{5}{3}<\beta<-1\right\}, & C_{22}:=\left\{(\alpha, \beta): \alpha=-\frac{1}{8},-1 \leq \beta<\psi\right\}, \\
C_{23}:=\left\{(\alpha, \beta): \alpha=-\frac{1}{8}, \psi \leq \beta<1\right\}, & C_{31}:=\left\{(\alpha, 16 \alpha+1):-\frac{1}{6}<\alpha<-\frac{1}{8}\right\}, \\
C_{32}:=\left\{(\alpha, 16 \alpha+1):-\frac{1}{8} \leq \alpha<-\frac{1}{8 \mu}\right\}, & C_{33}:=\left\{(\alpha, 16 \alpha+1):-\frac{1}{8 \mu} \leq \alpha<0\right\},
\end{array}
$$

where $\psi:=-1+\frac{2}{1+\theta}$. The values of $\gamma_{i j}$ and $\delta:=\left(1-\gamma_{11}\right)\left(1-\gamma_{22}\right)-\gamma_{12} \gamma_{21}$ on the different segments are shown in the following table:

| Segment | $\gamma_{11}$ | $\gamma_{22}$ | $\gamma_{12}$ | $\gamma_{21}$ | $\delta$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $C_{11}$ | $\mu / 2$ | 0 | 2 | $-2 \mu\left(\alpha+\frac{1}{8}\right)$ | $1+4 \mu \alpha$ |
| $C_{12}$ | $\mu / 2$ | 0 | 2 | $2 \mu\left(\alpha+\frac{1}{8}\right)$ | $1-\mu-4 \mu \alpha$ |
| $C_{21}$ | $\frac{\mu}{4}(1-\beta)$ | $-\frac{1+\beta}{2}$ | $1-\beta$ | $-\frac{\mu}{8}(\beta+1)$ | $\frac{1}{4}(6-\mu+\beta(\mu+2))$ |
| $C_{22}$ | $\frac{\mu}{4}(1-\beta)$ | $\frac{1+\beta}{2}$ | $1-\beta$ | $\frac{\mu}{8}(\beta+1)$ | $\frac{1}{4}(1-\beta)(2-\mu)$ |
| $C_{23}$ | $\frac{1}{2}$ | $\frac{1+\beta}{2}$ | $1-\beta$ | $\frac{\mu}{8}(\beta+1)$ | $\frac{1}{8}(1-\beta)(2-\mu-\mu \beta)$ |
| $C_{31}$ | $-4 \mu \alpha$ | $-1-8 \alpha$ | $-16 \alpha$ | $-\frac{\mu}{4}(1+8 \alpha)$ | $2+4 \alpha(2+\mu)$ |
| $C_{32}$ | $-4 \mu \alpha$ | $1+8 \alpha$ | $-16 \alpha$ | $\frac{\mu}{4}(1+8 \alpha)$ | $-4 \alpha(2-\mu)$ |
| $C_{33}$ | $\frac{1}{2}$ | $1+8 \alpha$ | $-16 \alpha$ | $\frac{\mu}{4}(1+8 \alpha)$ | $4(\mu-1) \alpha+32 \mu \alpha^{2}$ |

where as before we set $\mu:=\frac{1}{\theta}+1$.
We have $C^{1}$-convergence for a specific value of $(\alpha, \beta)$ provided we can find a $\theta>0$ so that $\delta>0$. This is always possible for any point in the open interval (see Figure 3.3).

Corollary 3.8. For $\alpha=\frac{\beta}{4(1-\beta)}$ and $\beta \in[-5 / 3,0)$, the scheme $H R C^{1}$ is $C^{1}$-convergent.

Proof. If $\beta \in[-5 / 3,0)$ and $\alpha=\frac{\beta}{4(1-\beta)}$, then $(\alpha, \beta) \in \mathcal{R}$, see Figure 3.1.

Figure 3.3: The value of $\delta=\left(1-\gamma_{11}\right)\left(1-\gamma_{22}\right)-\gamma_{12} \gamma_{21}$ on the curve segments defined by $\beta=-1$ (left), $\alpha=-\frac{1}{8}$ (center) and $\beta=16 \alpha+1$ (right) corresponding to $\theta=10$ or $\mu=1.1$.

## 4 The control grid

In order to obtain a geometric formulation of the $H R C^{1}$-algorithm we define control coefficients $a_{i j}$ and control points $A_{i j}$ relative to the rectangle $R=[a, b] \times$ $[c, d]$ as follows:

$$
\begin{align*}
& A_{00}=\left(a, c, a_{00}\right), \quad \text { where } a_{00}=f(a, c), \\
& A_{10}=\left(a+\frac{h}{\lambda}, c, a_{10}\right), \text { where } a_{10}=f(a, c)+\frac{h p(a, c)}{\lambda}, \\
& A_{20}=\left(b-\frac{h}{\lambda}, c, a_{20}\right), \text { where } a_{20}=f(b, c)-\frac{h p(b, c)}{\lambda}, \\
& A_{30}=\left(b, c, a_{30}\right), \quad \text { where } a_{30}=f(b, c), \\
& A_{31}=\left(b, c+\frac{k}{\lambda}, a_{31}\right), \text { where } a_{31}=f(b, c)+\frac{k q(b, c)}{\lambda}, \\
& A_{32}=\left(b, d-\frac{k}{\lambda}, a_{32}\right), \text { where } a_{32}=f(b, d)-\frac{k q(b, d)}{\lambda}, \\
& A_{33}=\left(b, d, a_{33}\right), \quad \text { where } a_{33}=f(b, d),  \tag{4.1}\\
& A_{23}=\left(b-\frac{h}{\lambda}, d, a_{23}\right), \text { where } a_{23}=f(b, d)-\frac{h p(b, d)}{\lambda}, \\
& A_{13}=\left(a+\frac{h}{\lambda}, d, a_{13}\right), \text { where } a_{13}=f(a, d)+\frac{h p(a, d)}{\lambda}, \\
& A_{03}=\left(a, d, a_{03}\right), \quad \text { where } a_{03}=f(a, d), \\
& A_{02}=\left(a, d-\frac{k}{\lambda}, a_{02}\right), \text { where } a_{02}=f(a, d)-\frac{k q(a, c)}{\lambda}, \\
& A_{01}=\left(a, c+\frac{k}{\lambda}, a_{01}\right), \text { where } a_{01}=f(a, c)+\frac{k q(a, c)}{\lambda} .
\end{align*}
$$

Here $h:=b-a, k:=d-c$ and $\lambda \geq 2$ is a real number to be chosen. The 12 control points are located on the boundary of $R$. We can obtain a control polygon-like structure by adding the four interiour points $A_{11}=A_{10}+A_{01}-A_{00}$, $A_{21}=A_{20}+A_{31}-A_{30}, A_{22}=A_{23}+A_{32}-A_{33}$, and $A_{12}=A_{13}+A_{02}-A_{03}$, see Figure 4.1.

Figure 4.1: Control Grid

If $f$ is the $H R C^{1}$-interpolant constructed from the given data at the vertices of $R$ then the parametric surface $(x, y, f(x, y))$ with $(x, y) \in R$ interpolates the corner control points $A_{00}, A_{03}, A_{30}, A_{33}$. Moreover each corner rectangle in the control polygon defines a plane which is part of the tangent plane at that vertex. For example the plane containing the four points $A_{00}, A_{10}, A_{01}$, and $A_{11}$ defines the tangent plane to the surface at $A_{00}$.

After one step of subdivision the rectangle $R$ is divided into four subrectangles (Cf. Figure 2.1). On each of the four sub-rectangles we can compute new control points $\bar{A}_{i j}$. To compute these control points we can use (4.1) shifted to each subrectangle. In particular, we replace $h$ and $k$ by $h / 2$ and $k / 2$ respectively.
By using (2.1), (2.2), (2.3) and (2.4) and inverting the formulas in (4.1) it is possible to express the new control coefficients $\left\{\bar{a}_{i j}\right\}$ in terms of the original

Figure 4.2: The control points projected on the original rectangle

Figure 4.3: The projected control points after one subdivision
control coefficients $a_{i j}$. We restrict attention to the one parameter family given by $\alpha=\beta /(4(1-\beta))$. We also write $\lambda=u(1-\beta)$, where $u$ is a free parameter to be chosen later. With the aid of a computer algebra system it can be proved that:
Proposition 4.1. Suppose $\alpha=\beta /(4(1-\beta))$ and $\lambda=u(1-\beta)$. With the indexing used in Figures 4.2 and 4.3 we have

where

$$
\begin{equation*}
\gamma:=-\beta, v:=u+1, w:=u-1, x:=1+u \beta, y:=2+u \beta \tag{4.2}
\end{equation*}
$$

We denote the transformation matrix by $S$.

## 5 Local shape constrains

We consider only the function case, where the starting data are values of $f, p$ and $q$ on the vertices of a rectangle $[a, b] \times[c, d]$ in $\mathbb{R}^{2}$. We consider the one
parameter family given by $\alpha=\frac{\beta}{4(1-\beta)}$ with $\beta \in[-1,0)$. Corollary 3.8 implies $C^{1}-$ convergence for any $\beta \in[-1,0)$. We let $\lambda=u(1-\beta)$, where $u$ is a free parameter. We also recall that for $\beta=-1$, the interpolant is the Sibson-Thomson element which is piecewise quadratic.

### 5.1 Positive interpolants

We prove that if the control grid is positive, then the interpolant is positive. We use this result to give an algorithm to get a positive interpolant whenever the initial data make it possible.

Proposition 5.1. Suppose that $1 \leq u \leq-1 / \beta$. If the initial control grid is positive, i.e. $a_{k \ell} \geq 0$ for all $k, \ell$, then the interpolant $f$ is positive.

Proof. With the hypothesis $1 \leq u \leq-1 / \beta$ and $-1 \leq \beta<0$ the quantities $\gamma, v, w, x, y$ in (4.2) are nonnegative so that all entries in the matrix $S$ in Proposition 4.1 are nonnegative. In the subdivision process we apply the matrix $S$ recursively and it follows that all control coefficients on all levels are nonnegative. But then the values of the function $f$ on $\cup\left(\mathcal{P}_{n} \times \mathcal{Q}_{n}\right)=\mathcal{P} \times \mathcal{Q}$ are nonnegative. We have the result on $[a, b] \times[c, d]$ by continuous extension.

We describe an algorithm to build a nonnegative interpolant on $[a, b] \times[c, d]$. Suppose that the initial data satisfy

$$
\begin{align*}
& f(a, c) \geq 0 \text { and }(p(a, c) \geq 0, q(a, c) \geq 0 \text { if } f(a, c)=0), \\
& f(b, c) \geq 0 \text { and }(p(b, c) \leq 0, q(b, c) \geq 0 \text { if } f(b, c)=0), \\
& f(a, d) \geq 0 \text { and }(p(a, d) \geq 0, q(a, d) \leq 0 \text { if } f(a, d)=0),  \tag{5.1}\\
& f(b, d) \geq 0 \text { and }(p(b, d) \leq 0, q(b, d) \leq 0 \text { if } f(b, d)=0) .
\end{align*}
$$

Algorithm 5.1. Let $h:=b-a, k:=d-c$ and choose $\lambda \geq 2$ such that

$$
\begin{array}{ccc}
a_{10}=f(a, c)+h \frac{p(a, c)}{} \geq 0 & , & a_{01}=f(a, c)+k \frac{q(a, c)}{p(\hat{l}} \geq 0, \\
a_{20}=f(b, c)-h \frac{p(b, c)}{\lambda} \geq 0 & , & a_{31}=f(b, c)+k \frac{q(b, c)}{\lambda} \geq 0, \\
a_{13}=f(a, d)+h \frac{p(a, d)}{\lambda} \geq 0 & , & a_{02}=f(a, d)-k \frac{q(a, d)}{(\hat{l}} \geq 0,  \tag{5.2}\\
a_{23}=f(b, d)-h \frac{p(b, d)}{\lambda} \geq 0 & , & a_{32}=f(b, d)-k \frac{q(b, d)}{\lambda} \geq 0 .
\end{array}
$$

Define $\beta=\frac{1}{1-\lambda}$ and $\alpha=\frac{\beta}{4(1-\beta)}$.
Perform HRC ${ }^{1}$ defined by (2.1), (2.2), (2.3) and (2.4).
Since $\lambda \geq 2$, we obtain $\beta \in[-1,0)$ so that the scheme is $C^{1}$-convergent. In view of (5.1), since $a_{00}=f(a, c) \geq 0, a_{30}=f(b, c) \geq 0, a_{33}=f(b, d) \geq 0$ and $a_{03}=f(a, d) \geq 0$ it is possible to choose $\lambda \geq 2$ so that the remaining control coefficients are nonnegative. By Proposition 5.1 the interpolant $f$ is nonnegative.

Example 5.1.
In Figure 5.1, we have computed three nonnegative $H R C^{1}$-interpolants choosing the same data on the vertices of $[0,1]^{2}$ except $p(0,1)$ which values are successively $-1,-1.5$ and -3 . The values of $\lambda$ are the smallest one so that (5.2) holds. In the first case $\left(f_{1}, p_{1}, q_{1}\right)$, we have $\lambda=2$ so that $\alpha=-1 / 8$ and $\beta=-1$ and we obtain the quadratic spline interpolant with piecewise linear derivatives.

Figure 5.1: Nonnegative interpolants

### 5.2 Monotone interpolants

We prove that if the control polygon is increasing in the variable $x$ then the interpolant is an increasing function in $x$. We use this result to give an algorithm to get an increasing interpolant in $x$ as soon as the data make it possible.
Lemma 5.2. Suppose that $u=-1 / \beta$ with $\beta \in[-1,0)$.

$$
\text { If }\left\{\begin{array} { r l } 
{ a _ { 0 0 } \leq a _ { 1 0 } \leq a _ { 2 0 } \leq a _ { 3 0 } , } \\
{ a _ { 0 1 } \leq a _ { 3 1 } , } \\
{ a _ { 0 2 } \leq a _ { 3 2 } , } \\
{ a _ { 0 3 } \leq a _ { 1 3 } \leq a _ { 2 3 } \leq a _ { 3 3 } , }
\end{array} \quad \text { then } \left\{\begin{array}{rl}
\bar{a}_{01} & \leq \bar{a}_{31} \leq \bar{a}_{61}, \\
\bar{a}_{02} \leq \bar{a}_{32} \leq \bar{a}_{62}, \\
\bar{a}_{03} \leq \bar{a}_{13} \leq \bar{a}_{23} \leq \bar{a}_{33} \leq \bar{a}_{43} \leq \bar{a}_{53} \leq \bar{a}_{63}, \\
\bar{a}_{04} \leq \bar{a}_{34} \leq \bar{a}_{64} \\
\bar{a}_{05} \leq \bar{a}_{35} \leq \bar{a}_{65} \\
\bar{a}_{06} \leq \bar{a}_{16} \leq \bar{a}_{26} \leq \bar{a}_{36} \leq \bar{a}_{46} \leq \bar{a}_{56} \leq \bar{a}_{66} .
\end{array}\right.\right.
$$

Proof. We define (Cf. Figures 4.2 and 4.3) horizontal differences $d_{i, j}:=$ $a_{i+1, j}-a_{i, j}$ for $i=0,1,2$ and $j=1,2, d_{0, j}:=a_{3, j}-a_{0, j}$ for $j=1,2, \bar{d}_{i, j}:=$ $\bar{a}_{i+1, j}-\bar{a}_{i, j}$ for $i=0,1, \ldots, 5$ and $j=0,3,6$, and $\bar{d}_{i, j}:=\bar{a}_{i+3, j}-\bar{a}_{i, j}$ for $i=0,3$ and $j=1,2,4,5$. We use the results of Proposition 4.1 and a computer algebra
system to obtain:

The hypothesis implies that $d_{k \ell} \geq 0$. Since $-1 \leq \beta<0$, we obtain $\bar{d}_{i j} \geq 0$.
We can extend the result recursively on each sub rectangle of $\mathcal{P}_{n} \times \overline{\mathcal{Q}}_{n}$. At each step the control grid is increasing in the direction $x$ so that the function $p$ is nonnegative on $\cup\left(\mathcal{P}_{n} \times \mathcal{Q}_{n}\right)=\mathcal{P} \times \mathcal{Q}$ By continuous extension $p$ is nonnegative on $[a, b] \times[c, d]$ and $f$ is increasing in $x$.

Proposition 5.3. Suppose that $u=-1 / \beta$ with $\beta \in[-1,0)$. If the initial grid is increasing in $x$, i.e. $\left\{\begin{aligned} a_{00} \leq a_{10} \leq a_{20} \leq a_{30}, \\ a_{01} \leq a_{31}, \\ a_{02} \leq a_{32}, \\ a_{03} \leq a_{13} \leq a_{23} \leq a_{33},\end{aligned}\right.$ then the interpolant $f$ is increasing in $x$.
We define an algorithm to construct an interpolant on $[a, b] \times[c, d]$ that is increasing in $x$. Suppose that the initial data satisfy
$p(a, c) \geq 0, p(b, c) \geq 0, f(a, c)<f(b, c)$ and $p(a, d) \geq 0, p(b, d) \geq 0, f(a, d)<f(b, d)$.

Figure 5.2: Increasing interpolants in the variable $x$

Algorithm 5.2. Let $h:=b-a, k=: d-c$ and choose $\lambda \geq 2$ such that

$$
\begin{align*}
& a_{10}=f(a, c)+h \frac{p(a, c)}{\lambda} \leq a_{20}=f(b, c)-h \frac{p(b, c)}{\lambda} \\
& a_{01}=f(a, c)+k \frac{q(a, c)}{\lambda}  \tag{5.3}\\
& \leq a_{31}=f(b, c)+k \frac{q(b, c)}{\lambda} \\
& a_{02}=f(a, d)-k \frac{q(a, d)}{\lambda} \leq a_{32}=f(b, d)-k \frac{q(b, d)}{\lambda} \\
& a_{13}=f(a, d)+h \frac{p(a, d)}{\lambda} \leq a_{23}=f(b, d)-h \frac{p(b, d)}{\lambda}
\end{align*}
$$

Define $\beta=\frac{1}{1-\lambda}$ and $\alpha=\frac{\beta}{4(1-\beta)}$.
Perform HRC ${ }^{1}$ defined by (2.1), (2.2), (2.3), and (2.4).
Since the $\beta$ used in this algorithm always belongs to the interval $[-1,0)$ the interpolating scheme is $C^{1}$-convergent. Morover, since $a_{00} \leq a_{10}, a_{20} \leq a_{30}$, $a_{03} \leq a_{13}, a_{23} \leq a_{33}$, the control grid and the interpolant $f$ are increasing in the variable $x$.

Example 5.2. In the 3 following pictures (Figure 5.2), we have computed three interpolants which are monotone in the $x$-direction. We choose the same data on the vertices of $[0,1]^{2}$ except $p(1,0)$ which values are successively $0.3,0.9$ and 1.8. The values of $\lambda$ are the smallest one satisfying (5.3). In the first case $\left(f_{1}, p_{1}, q_{1}\right)$, we have $\lambda=2$ so that $\alpha=-1 / 8$ and $\beta=-1$ and we obtain the quadratic spline interpolant with piecewise linear derivatives.

## 6 Examples of global constrains

### 6.1 The First Example

We start with the grid defined by

$$
\left\{\left(x_{i}, y_{j}\right)\right\}=\{0,0.25,0.7,0.92,1\} \times\{0,0.2,0.6,1\}
$$

and sub-rectangles $R_{i, j}, i=1, \ldots, 4, j=1, \ldots, 3$. The initial data for the function $f$ at the vertices of the grid are

| $x \backslash y$ | 0 | 0.2 | 0.6 | 1 |
| :--- | :---: | :---: | :---: | :---: |
| 0 | 0 | -0.9511 | 0.5878 | 0.0000 |
| 0.25 | 0.0625 | -0.8886 | 0.6503 | 0.0625 |
| 0.7 | 0.4900 | -0.4611 | 1.0778 | 0.4900 |
| 0.92 | 0.8464 | -0.1047 | 1.7000 | 1.7000 |
| 1 | 1.0000 | 0.0489 | 1.7000 | 1.7000 |

They are stricly increasing along $x$ except that $f(0.92,0.6)=f(1,0.6)=f(0.92,1)$ $=f(1,1)$. Since the initial data where sampled from the function $f(x, y)=$ $x^{2}-\sin (2 \pi y)$, we compute the exact derivatives $p$ and $q$ and we add a random number in $[0,0.2]$ for $p$. We have an exception for $R_{4,3}$. We choose the example:

| $p$ |  |  |  |  |  |  |  | $q$ |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $x \backslash y$ | 0 | 0.2 | 0.6 | 1 | $x \backslash y$ | 0 | 0.2 | 0.6 | 1 |  |  |  |  |  |
| 0 | 0.0388 | 0.1098 | 0.1255 | 0.1675 | 0 | -6.2832 | -5.0832 | 1.9416 | 6.2832 |  |  |  |  |  |
| 0.25 | 0.6810 | 0.6863 | 0.6398 | 0.5743 |  | 0.25 | -6.2832 | -5.0832 | 1.9416 |  |  |  |  |  |
| 0.2832 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0.7 | 1.5138 | 1.4670 | 1.4794 | 1.4851 | 0.70 | -6.2832 | -5.0832 | 1.9416 | 6.2832 |  |  |  |  |  |
| 0.92 | 1.9664 | 1.9711 | 0 | 0 | 0.92 | -6.2832 | -5.0832 | 0 | 0 |  |  |  |  |  |
| 1 | 2.0469 | 2.0784 | 0 | 0 | 1 | -6.2832 | -5.0832 | 0 | 0 |  |  |  |  |  |

All the derivatives $p=f_{x}$ are nonnegative except $p(0.92,0.6)=p(1,0.6)=$ $p(0.92,1)=p(1,1)=0$. We add $q(0.92,0.6)=q(1,0.6)=q(0.92,1)=q(1,1)=$ 0.

On each subrectangle $R_{i, j}$, we compute the smallest $\lambda_{i, j} \geq 2$ which gives an increasing control grid in the variable $x$. For the rectangle $R_{4,3}$, we can built a constant interpolant with any $\lambda_{4,3}$. Let us choose $\lambda_{4,3}=2$. Then we compute $\lambda=\max \lambda_{i, j}, \beta=\frac{1}{1-\lambda}$ and $\alpha=\frac{\beta}{4(1-\beta)}$. On each subrectangle, we perform $H R C^{1}$ defined by (2.1), (2.2), (2.3) and (2.4). See Figure 6.1.

### 6.2 The Second Example

This example was proposed in [2]. The initial grid is $\{-0.07,0.33,0.55,0.69,0.84$, $0.93,0.98,1.02,1.08,1.13\} \times\{-2.3,-1.61,-0.92,-0.51,-0.22,0.0\}$, and we will use the sub-rectangles $R_{i, j}, i=1, \ldots, 9, j=1, \ldots, 5$. The given data $f_{i, j}^{0}$ of the

Figure 6.1: Increasing interpolant in the variable $x$ on a mesh with , $\lambda=3.1843$
function $f$ are

| $x \backslash y$ | -2.3 | -1.61 | -0.92 | -0.51 | -0.22 | 0.0 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| -0.07 | -34.5400 | -13.8200 | -10.1000 | -7.2600 | -5.6600 | -4.5300 |
| 0.33 | -34.5400 | -13.8200 | -10.1000 | -7.2600 | -5.6600 | -4.1300 |

The data are increasing in the directions $x$ and $y$ (see Figure 6.2) so that we will choose non negative derivatives $p$ and $q$ to get an increasing interpolant in both directions. Notice that if $f_{i, j}^{0}=f_{i+1, j}^{0}$, we must choose $p_{i, j}^{0}=p_{i+1, j}^{0}=0$ and $q_{i, j}^{0}=q_{i+1, j}^{0}$ and similarly on the other direction. With this exception, we can choose any non negative derivatives $p_{i, j}^{0}$ and $q_{i, j}^{0}$ to get an increasing interpolant in both directions. Again on each sub-rectangle $R_{i, j}$, we compute the smallest $\lambda_{i, j} \geq 2$ which gives an increasing control grid in the variable $x$ and in the variable $y$. Then we compute $\lambda=\max \lambda_{i, j}, \beta=\frac{1}{1-\lambda}$ and $\alpha=\frac{\beta}{4(1-\beta)}$. On each sub-rectangle, we perform $H R C^{1}$ defined by (2.1), (2.2), (2.3) and (2.4).

Figure 6.2: Initial Mesh and Function.

Case 1: We have computed the initial derivatives $p_{i, j}^{0}$ and $q_{i, j}^{0}$ using the standard two point forward differences. The computed value is $\lambda=4.5455$. See Figure 6.3.

Case 2: We took random positive derivatives (between 0 and 2). The computed value is $\lambda=4.9861$. See Figure 6.4.

## 7 Final Remarks

1. In the shape preserving algorithms the subdivision was carried out using the $H R C^{1}$-algorithm. The control coefficients were used only to choose parameters to ensure a final interpolant with the desired shape.
2. By applying Proposition 4.1 it is possible to reformulate the $H R C^{1}$ scheme as a stationary subdivision scheme working on points in $\mathbb{R}^{s}$. We start with 12 control coefficients $a_{0,0}, a_{1,0}, a_{2,0}, a_{3,0}, a_{0,1}, a_{3,1}, a_{0,2}, a_{3,2}, a_{0,3}, a_{1,3}, a_{2,3}, a_{3,3}$ in $\mathbb{R}^{s}, s \geq 1,(\alpha, \beta)$ in the convergence region in Figure 3.1, and $\lambda \geq 2$. Under suitable restrictions on the "rectangular structure" of the initial control coefficients we could then define an algorithm $S R C^{1}$ based on recursively using the matrix $S$. However we will not consider this any further here.
3. We note that $S$ has negative minors and thus is not a totally positive matrix. For example the $2 \times 2$ minor constructed from the entries in rows 2 and 8 and columns 1 and 2 has the value $-1 / 4$ for all values of $\alpha, \beta$ and $\lambda$.
4. Unfortunately, the algorithm $H R C^{1}$ is in general not able to give a convex interpolant when starting with convex data. To see this we consider the

Figure 6.3: Increasing interpolant using forward differences to estimate derivatives.
function given by

$$
\phi(x, y):=\left\{\begin{array}{l}
(1-x-y)^{3} \text { if } 1-x-y \geq 0 \\
0 \text { if } 1-x-y \leq 0
\end{array}\right.
$$

This function is $C^{2}$ and convex on $[0,1]^{2}$. To construct a convex $H R C^{1}$ interpolant $f$ we note that $f$ must be convex along the diagonal $\delta:=$ $\left\{(x, y) \in[0,1]^{2}: x+y=1\right\}$. Since $\phi$ and its partial derivatives vanish at the two corners $(1,0)$ and $(0,1)$ the same holds true for $f$. This means that $f$ must vanish identically on $\delta$. We now show that this is not possible regardless of how we choose $\alpha$ and $\beta$.
At step 0 , we sample the function and its derivatives on the vertices of the square $[0,1]^{2}$ and we obtain $f_{i, j}^{0}=p_{i, j}^{0}=q_{i, j}^{0}=0$ for $(i, j) \neq(0,0)$ and $f_{0,0}^{0}=1, p_{0,0}^{0}=q_{0,0}^{0}=-3$. Using (2.4) we compute the values at the midpoint $(1 / 2,1 / 2)$. We find $f_{11}^{1}=\frac{1}{4}+3 \alpha$ and $p_{11}^{1}=q_{11}^{1}=-\frac{1}{2}-\beta$. Convexity on $\delta$ implies that $\alpha=-1 / 12$ and $\beta=-1 / 2$. Moreover for these values of the parameters we must have $f_{i j}^{n}=0$ for all points on $\delta$. But already the value $f_{31}^{2}$ at the point $(3 / 4,1 / 4)$ on $\delta$ is nonzero. To see this

Figure 6.4: Increasing interpolant with random derivatives.
we first compute $f_{1,0}^{1}=1 / 4, p_{1,0}^{1}=-3 / 4, q_{1,0}^{1}=-3 / 2$ by (2.2), and then $f_{2,1}^{1}=p_{2,1}^{1}=q_{2}^{1}{ }_{1}=0$ by (2.3). We now find $f_{3,1}^{2}=1 / 64 \neq 0$ using (2.4). Thus the $H R C^{1}$-interpolant is not convex.
