**Abstract.** In this paper, we used the multiconfiguration Dirac-Fock method to compute with high precision the influence of the hyperfine interaction on the  $[Ar]3d^{10}4s4p\ ^3P_0$  level lifetime in Zn-like ions for stable and some quasi-stable isotopes of nonzero nuclear spin between  $Z = 30$  and  $Z = 92$ . The influence of this interaction on the  $[Ar]3d^{10}4s4p\ ^3P_1 - [Ar]3d^{10}4s4p\ ^3P_0$  separation energy is also calculated for the same ions.

## 1 Introduction

It has been found before that the hyperfine interaction plays a fundamental role in the lifetimes and energy separations of the  $^3P_0$  and  $^3P_1$  levels of the configurations  $1s2p$  in He-like [1, 2, 3, 4, 5, 6, 7, 8, 9],  $[He]2s2p$  in Be-like [10, 11, 12], and  $[Ne]3s3p$  in Mg-like [11, 13] ions, and also in  $3d^4J = 4$  level in the Ti-like ions [14].

In the He-like ions, in the region  $Z \approx 45$ , these two levels undergo a level crossing [15] and are nearly degenerate due to the electron-electron magnetic interaction, which leads to a strong influence of the hyperfine interaction on the energy splitting and on the  $^3P_0$  lifetime for isotopes with nonzero nuclear spin. In Be-like, Mg-like and Zn-like ions a level crossing of the  $^3P_0$  and  $^3P_1$  levels has not been found [16], but hyperfine interaction still has strong influence on the lifetime of the  $^3P_0$  metastable level and on the energy splitting, for isotopes with nonzero nuclear spin.

Until recently, laboratory measurements of atomic metastable states hyperfine quenching have been performed only for He-like systems, for  $Z = 28$  to  $Z = 79$  [3, 4, 5, 8, 17, 18, 19, 20]. Hyperfine-induced transition lines in Be-like systems have been found in the planetary nebula NGC3918 [12]. Measured values of transition probabilities were found to agree with computed values [11, 21].

Divalent atoms are being investigated, both theoretically and experimentally, in order to investigate the possible use of the hyperfine quenched  $^3P_0$  metastable state for ultraprecise optical clocks and trapping experiments [22].

Recently, dielectronic recombination rate coefficients were measured for three isotopes of Zn-like  $Pt^{48+}$  in the

Heidelberg heavy-ion storage ring TSR [23]. It was suggested that hyperfine quenching of the  $4s4p\ ^3P_0$  in isotopes with non-zero nuclear spin could explain the differences detected in the observed spectra.

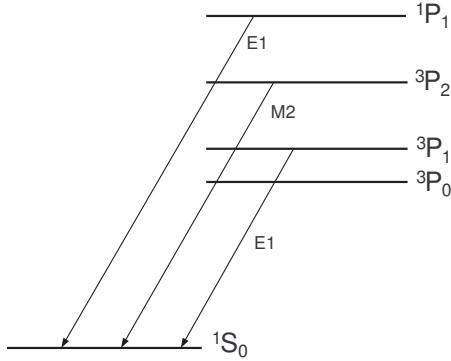

In this paper we extend our previous calculations [2, 10, 13] to the influence of the hyperfine interaction on the  $1s^22s^22p^63s^23p^63d^{10}4s4p$  levels in Zn-like ions.

In Fig. 1 we show the energy level scheme, not to scale, of these ions. The  $^3P_0$  level is a metastable level; one-photon transitions from this level to the ground state are forbidden, and multiphoton transitions have been found to be negligible in similar systems, so the same behavior can be expected for Zn-like ions. Therefore, in first approximation, we will consider the lifetime of this level as infinite. The energy separation between the  $4\ ^3P_0$  and  $4\ ^3P_1$  levels is small for  $Z$  values around the neutral Zn atom and increases very rapidly with  $Z$ . Hyperfine interaction is expected to have a strong influence on the energy splitting and on the  $4\ ^3P_0$  lifetime for isotopes with nonzero nuclear spin.

The different steps of this calculation are described in Refs. [2, 24]. Here we will emphasize only the fundamental topics of the theory and the characteristic features of Zn-like systems.

In this work we used the multi-configuration Dirac-Fock code of Desclaux and Indelicato [25, 26, 27] to evaluate, completely *ab initio* the  $4s4p$  fine structure energies and transition probabilities.

Several terms, such as the nonrelativistic ( $J$  independent) contribution to the correlation, are the same for all levels. In this calculation Breit interaction is included, as well as radiative corrections, using the method described,

**Fig. 1.** Energy level and transition scheme for Zn-like ions (not to scale).

for instance, in Ref. [28] and references therein. The MCDF method, in principle, allows for precise calculations because it can include most of the correlation relatively easily, i. e., with a small number of configurations. Here, correlation is important in the determination of transition energies to the ground state, which are used in the calculation of transition probabilities. We found that the largest effect is obtained by using  $[Ar]3d^{10}4s^2$  and  $4p^2$  as the configuration set for the ground state. For the excited states we included all configuration state functions (CSF) originated from  $[Ar]3d^{10}4s4p$ ,  $4p4d$ , and  $4d4f$  (which is usually defined as intrashell correlation), because in second-order perturbation theory the dominant energy difference denominators correspond to these configurations. Correlation originating from interaction with the Ar-like core has been neglected. In particular we included, in a test calculation, spin-polarization from  $s$  subshells and found a negligible influence in both energies and transition probabilities. We note that the fine structure energy separation,  $\Delta E_{0;fs} = E_{^3P_1} - E_{^3P_0}$ , which is the important parameter in the calculation of the hyperfine quenching, is not very sensitive to correlation, similarly to what we found for systems with smaller number of electrons [10,13]. The same set of CSF have been used for energy, transition probabilities, and for the calculation of the hyperfine matrix elements.

All energy calculations are done in the Coulomb gauge for the retarded part of the electron-electron interaction, to avoid spurious contributions (see for example Refs. [29, 31]). The lifetime calculations are all done using exact relativistic formulas. The length gauge has been used for all transition probabilities.

## 2 Relativistic calculation of hyperfine contribution to fine structure splitting and to transition probabilities

In the case of a nucleus with nonzero spin, the hyperfine interaction between the nucleus and the electrons must be taken into account. The correspondent Hamiltonian can

be written as

$$H_{\text{hfs}} = \sum_k \mathbf{M}^{(k)} \cdot \mathbf{T}^{(k)}, \quad (1)$$

where  $\mathbf{M}^{(k)}$  and  $\mathbf{T}^{(k)}$  are spherical tensors of rank  $k$ , representing, respectively, the nuclear and the atomic parts of the interaction. As in the case of He-like, Be-like and Mg-like ions, the only sizable contribution from Eq. (1) is the magnetic dipole term ( $k = 1$ ). The hyperfine interaction mixes states with the same  $F = J + I$  values. In our case, we are interested in the  $^3P_0$  level, so  $J = 0$  and  $F = I$ . The contribution of this interaction for the total energy has been evaluated through the diagonalization of the matrix:

$$H_{\text{tot}} = \begin{bmatrix} E_0 + \frac{1}{2}i\Gamma_0 + W_{0,0} & W_{0,1} & W_{0,2} \\ W_{1,0} & E_1 + \frac{1}{2}i\Gamma_1 + W_{1,1} & W_{1,2} \\ W_{2,0} & W_{2,1} & E_2 + \frac{1}{2}i\Gamma_2 + W_{2,2} \end{bmatrix} \quad (2)$$

Here,  $E_f$  is the unperturbed level energy and  $\Gamma_f$  is the radiative width of the unperturbed level ( $f = 0, 1, 2$  stands, respectively, for  $^3P_0, ^3P_1, ^1P_1$ ). In reality there is a fourth level,  $^3P_2$ , which we included in all calculations but was found unnecessary, because the influence of this level in the  $^3P_0$  lifetime is negligible. This can be explained by the large energy separation between the  $^3P_2$  and  $^3P_0$  levels and also because the probability of the allowed M2 transition  $4s4p\ ^3P_2 \rightarrow 4s^2\ ^1S_0$  is many orders of magnitude smaller than those of the E1 transitions  $4s4p\ ^3P_1 \rightarrow 4s^2\ ^1S_0$  and  $4s4p\ ^1P_1 \rightarrow 4s^2\ ^1S_0$ . Also, the magnetic dipole hyperfine matrix element between the  $^3P_2$  and  $^3P_0$  levels is very small. This also leads to a negligible influence of the  $^3P_2$  level on the  $^3P_1 - ^3P_0$  separation energy. This is consistent with the results of Plante e Johnson [32], who found that the magnetic quadrupole term of the hyperfine interaction affects the  $^3P_2$  level only at high  $Z$ . The influence of the  $^1P_1$  level, however, must be taken into account, specially for light nuclei, because the large energy separation between  $^1P_1$  and  $^3P_0$  levels is compensated by the much shorter lifetime of the  $^1P_1$  level. The

hyperfine matrix element

$$W_{f,f'} = W_{f',f} = \langle [\text{Ar}] 3d^{10}4s4p f | H_{hf} | [\text{Ar}] 3d^{10}4s4p f' \rangle$$

may be written as

$$W_{J_1,J_2} = \langle I, J_1, F, M_F | \mathbf{M}^{(1)} \cdot \mathbf{T}^{(1)} | I, J_2, F, M_F \rangle, \quad (3)$$

where  $I$  is the nuclear spin and  $F$  the total angular momentum of the atom, and may be put in the form:

$$\begin{aligned} W_{J_1,J_2} &= (-1)^{I+J_1+F} \left\{ \begin{array}{ccc} I & J_1 & F \\ J_2 & I & 1 \end{array} \right\} \\ &\times \langle I | \mathbf{M}^{(1)} | I \rangle \langle J_1 | \mathbf{T}^{(1)} | J_2 \rangle. \end{aligned} \quad (4)$$

The  $6j$  symbol leads to  $W_{0,0} = 0$ . Also the nuclear magnetic moment  $\mu_I$  in units of the nuclear magneton  $\mu_N$  may be defined by

$$\mu_I \mu_N = \langle I | \mathbf{M}^{(1)} | I \rangle \begin{pmatrix} I & 1 & I \\ -I & 0 & I \end{pmatrix}, \quad (5)$$

with  $\mu_N = e\hbar/2\pi m_p c$ .

The electronic matrix elements were evaluated on the basis set  $|^3P_0\rangle$ ,  $|^3P_1\rangle$ ,  $|^1P_1\rangle$  with all intrashell correlation included.

The final result is then obtained by a diagonalization of the  $3 \times 3$  matrix in Eq. (2), the real part of each eigenvalue being the energy of the correspondent level and the imaginary part its lifetime.

### 3 Results and discussion

The MCDF method has been used to evaluate the influence of the hyperfine interaction on the  $[\text{Ar}]3d^{10}4s4p\ ^3P_0$ ,  $^3P_1$  and  $^1P_1$  levels for all  $Z$  values between 30 and 92 and for all stable and some quasi-stable isotopes of nonzero nuclear spin. Contributions from other levels have been found to be negligible. A detailed list of the contributions to the theoretical  $^3P_0$ ,  $^3P_1$  and  $^1P_1$  level energies is presented in Table 1, for  $Z = 36, 54$ , and  $82$ .

In Table 2 we present, for all possible values of the nuclear spin  $I$ ,  $Z$ , and the mass number  $A$ , the diagonal and off-diagonal hyperfine matrix elements  $W_{i,j}$ , and the nuclear magnetic moment,  $\mu_I$  [37], in nuclear magneton units. The indexes 0, 1, and 2 in the hyperfine matrix elements stand for  $^3P_0$ ,  $^3P_1$ , and  $^1P_1$ , respectively.

In Table 3 are presented, for all possible values of  $I$ ,  $Z$ , and  $A$ , the unperturbed separation energies  $\Delta E_0 = E_{^3P_1} - E_{^3P_0}$ , the hyperfine-affected separation energy  $\Delta E_{\text{hf}}$ , the  $4s4p\ ^3P_1$  and  $4s4p\ ^1P_1$  levels lifetime values,  $\tau_1$  and  $\tau_2$ , respectively, which are not affected, within the precision shown, by the hyperfine interaction, and finally the perturbed lifetime  $\tau_0$  of the  $4s4p\ ^3P_0$  level. As we pointed out before, the unperturbed value of  $\tau_0$  is assumed to be infinite.

In Fig. 2 is plotted the difference  $E = \Delta E_{\text{hf}} - \Delta E_0$  as a function of  $Z$  for the different possible values of nuclear spin. The influence of the hyperfine interaction on this

energy is shown to increase slowly with  $Z$ , the increase becoming more rapid for  $Z \gtrsim 60$ .

In Fig. 3 is plotted the perturbed  $4s4p\ ^3P_0$  level lifetime  $\tau_0$ , for the different nuclear spin values  $I$ , as a function of  $Z$ . One can easily conclude that the opening of a new channel for the decay of the  $4s4p\ ^3P_0$  level has a dramatic effect on its lifetime.

After submitting this paper, it was brought to our attention the work by Liu *et al* [38], which contains independent calculations of the hyperfine quenched lifetime of the  $^3P_0$  level in several Zn-like ions. Our results for this lifetime are three times higher than the values found by Liu *et al* for  $Z = 30$  and 1.5 higher at  $Z = 47$ . To look for the origin of this discrepancy we used the  $^3P_1 \rightarrow ^1S_0$  and  $^1P_1 \rightarrow ^1S_0$  transition energies and probabilities of Liu *et al* to diagonalize the matrix in eq. 2 and obtained results very close to our own calculations. As we do not know the values of the hyperfine matrix elements calculated by Liu *et al*, the reasons for this discrepancy remain unknown.

One of the most interesting practical implication of these calculations comes from the relationship between the  $4s4p\ ^3P_0 - 4s4p\ ^3P_1$  levels energy separation and the  $4s4p\ ^3P_0$  level lifetime (Eq. 2). As referred in [13] this energy separation can be estimated from a measurement of the hyperfine-quenched  $4s4p\ ^3P_0$  lifetime of Zn-like ions with nuclear spin  $I \neq 0$ . This method has been demonstrated for heliumlike  $\text{Ni}^{26+}$  [4],  $\text{Ag}^{45+}$  [3],  $\text{Gd}^{62+}$  [17] and  $\text{Au}^{77+}$  [8]. In the Zn-like ions case, as in the corresponding Be-like and Mg-like ions, the situations is different, because, even for the highest  $Z$  values, the lifetimes involved are much longer than in heavy heliumlike ions. However, measurements of Be-like hyperfine quenched transition rates have been performed from astrophysical sources [12] and the hyperfine quenching of the Zn-like  $^{195}\text{Pt}^{48+}$  ion was observed in the TSR heavy-ion storage-ring [23].

The continuous progress in storage rings, ion sources and ion traps leads us to believe that lifetimes between 0.1 s and 10  $\mu\text{s}$  could be measured, with some accuracy, by directly looking at the light emitted by the ions as a function of time, after the trap has been loaded. Very good vacuum inside the trap is needed, of course, if long lifetimes are to be measured. It remains to be demonstrated that this method is experimentally feasible. Such experiments would be able to provide, for different isotopes, the unperturbed energy separation, because nuclear magnetic moments are well known. This would be an interesting way to test our relativistic calculations.

<sup>†</sup> Contains the Uheling potential contribution to all order and all order Breit interaction.

<sup>‡</sup> Calculated using the results of Ref. [33,34,35].

<sup>#</sup> The formulas and definitions used to evaluate this term are Appendix A of Ref. [36]

**Fig. 2.** Influence of the hyperfine interaction on the  $4s4p\ ^3P_1 - ^3P_0$  energy separation, as a function of the nuclear spin  $I$  and the atomic number  $Z$ . The quantity  $E = \Delta E_{\text{hf}} - \Delta E_0$  is the contribution of the hyperfine interaction to the fine structure splitting  $\Delta E_0$ . The symbols represent values for the different nuclear spins; some elements have several isotopes with identical  $\mu_I$  values.

**Fig. 3.** Influence of the hyperfine interaction on the lifetime of the  $4s4p\ ^3P_0$  level, as a function of the nuclear spin  $I$  and the atomic number  $Z$ . The unperturbed lifetime is, to a very good approximation, infinite.

**Table 2.** Hyperfine Matrix elements  $W_{i,j}$  in eV. The indexes 0, 1, and 2 stand for  $^3P_0$ ,  $^3P_1$ , and  $^1P_1$  respectively.  $I$  is the nuclear spin and  $\mu$  the nuclear magnetic moment in nuclear magneton units.

**Table 3.** Influence of the hyperfine interaction on the  $4s4p\ ^3P_1 - 4s4p\ ^3P_0$  energy separation and on the lifetime of the  $^3P_0$  level, as a function of the nuclear spin  $I$  and the atomic number  $Z$ .  $\Delta E_0$  is the unperturbed energy separation (in eV), and  $\Delta E_{hf}$  is the perturbed energy (in eV) when the hyperfine interaction is taken into account (the 5 digits do not necessarily represent the accuracy of the calculation - they are intended to show the effect at low  $Z$ ).  $\tau_0$ ,  $\tau_1$  and  $\tau_2$  represent the perturbed lifetimes (in s) of  $4s4p\ ^3P_0$ ,  $^3P_1$  and  $^1P_1$  levels respectively.
