Abstract: C₂₁₋₂₉ triaromatic steroid hydrocarbons bearing a methyl group at unusual positions 2, 3 or 6 have been synthesized from pregnenolone, cholesterol or stigmasterol *via* stera-3,5-dienes. Their occurrence in various sedimentary rocks and petroleums suggests the presence of yet unknown biological precursors.

INTRODUCTION

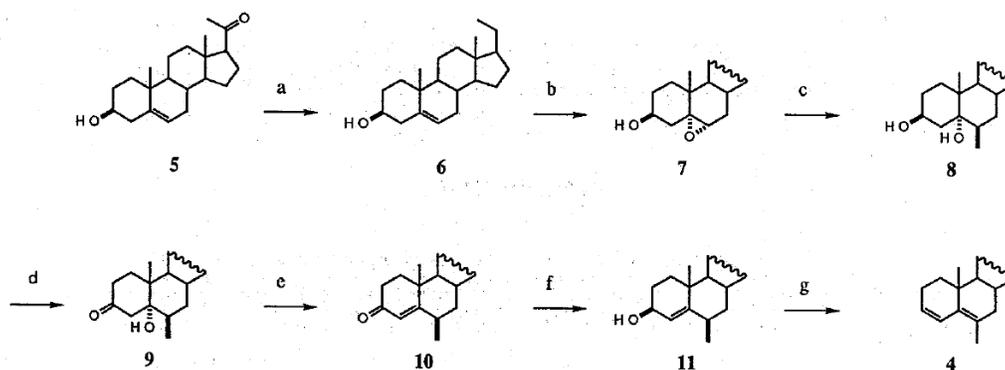

After deposition at the bottom of lakes and seas, sedimentary organic matter undergoes various chemical transformations such as dehydration, hydrogenation and aromatization, under the effect of temperature, time and mineral catalysis, leading to the formation of products which are usually less polar and thus easier to analyse than their functionalized biological precursors.¹ The discovery of structurally uncommon substances in sediments may therefore indicate the presence of yet unknown substances in living organisms. For example, the identification of C₃₁-C₃₅ hopanes in geological samples has prompted the discovery of novel bacterial lipids such as hopanetetrol.² The recent identification of triaromatic steroid hydrocarbons bearing a methyl group at position 2, 3 or 6 (**1-3**) in sedimentary rocks and petroleums³ is puzzling since possible steroidal precursors are rare in living organisms.^{3,4} Moreover, the concomitant occurrence of 3 β -alkylsteranes,⁵ 3 β -carboxysteranes⁶ and 3-methyltriaromatic steroid hydrocarbons³ in various sediments is of particular importance because nearly all biological sterols bear an alcohol group at position 3 β which has essential biochemical functions. We wish to report here the synthesis of triaromatic steroid hydrocarbons methylated at unusual positions 2, 3 or 6.

RESULTS AND DISCUSSION

Synthesis of 6-methylpregna-3,5-diene **4**

Wolff-Kishner reduction⁷⁻⁹ of pregnenolone **5** gave quantitatively the unsaturated alcohol **6** (scheme 1). Epoxidation^{10,11} of **6** with metachloroperbenzoic acid led to the epoxide **7**¹² in good yield (93%). The epoxide **7** was further methylated with methyl magnesium iodide¹³ in refluxing toluene-diethyl ether. Noteworthy, no conversion was observed during attempts to open the epoxide ring of **7** with methyl magnesium iodide at 0°C or lithium dimethyl copper. The secondary alcohol function of the diol **8** was then selectively oxidized with Jones reagent¹⁴ to give the keto-ol **9**. Ster-5 β -ol-3-ones may be dehydrated either in acidic¹⁵ or basic¹⁴ media. Thus, treatment of **9** with *p*-toluenesulfonic acid monohydrate furnished rapidly the α,β -unsaturated ketone **10**. The reduction of cholest-4-en-3-one with lithium aluminium hydride in refluxing diethyl ether is known to give two alcoholic diastereoisomers.¹⁶ Only the more stable 3 β -OH epimer **11** was formed by treatment of **10** with lithium aluminium hydride at -78°C.¹⁷ Stera-3,5-diol,¹⁸ ster-4-en-3-ol¹⁹ and ster-5-en-3-ol²⁰ may be dehydrated in acidic media. Accordingly, the allylic alcohol **11** was rapidly dehydrated with *p*-toluenesulfonic acid monohydrate at room temperature to afford the conjugated 3,5-diene **4**. The absence of other possible dienes, such as 2,4- or 4,6-diene, was confirmed by ¹H-NMR analysis.

Synthesis of 3-methylstera-3,5-dienes **12-14**

Acetylation of stigmasterol **15**²¹ was followed by selective 22-23 double bond hydrogenation of the acetate **16**²¹ over platinum dioxide²² to give the acetate **17** (scheme 2). This hydrogenation must be carefully followed by thin layer chromatography over silica gel impregnated with silver nitrate to avoid further hydrogenation of the less reactive 5-6 double bond. Subsequent hydrolysis of **17** with potassium hydroxide afforded the unsaturated alcohol **18**.²¹ Oppenauer oxidation²³ of pregn-5-en-3 β -ol **6**,⁷ cholesterol **19**²³ and stigmast-5-en-3 β -ol **18**²¹ with aluminium *tert*-butoxide furnished the conjugated enones **20-22**. Methylation of cholest-4-en-3-one **21** has been previously performed with methyl magnesium iodide.¹⁹ Treatment of the enones **20-22** with methyl lithium at -

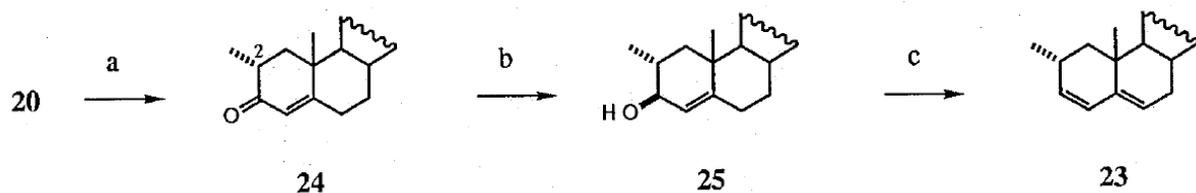

23°C followed by dehydration of allylic alcohol epimers with *p*-toluenesulfonic acid monohydrate gave the 3-methyl-3,5-dienes **12-14** in good overall yields (81-99%).

Synthesis of 2 α -methyl-3,5-diene **23**

Ster-4-en-3-ones are selectively methylated in the α' position by treatment of the kinetic dienolate with methyl iodide.^{24,25} Thus, the α' -methylated enone **24** was obtained from the enone **20** after basic equilibration²⁵ of the 2 ξ -methyl epimers to the more stable 2 α position (scheme 3). Noteworthy, these two epimers are separable by gas chromatography. Reduction of the enone **24** with lithium aluminium hydride at -78°C afforded only the unsaturated alcohol **25** which was then dehydrated in acid medium to give the 3,5-diene **23**. ¹H-NMR spectrum of **23** shows a doublet for the 2 α -methyl group, thus excluding possible 1,3- or 2,4-dienes.

Synthesis of triaromatic steroid hydrocarbons

The C-19 methyl group of stera-3,5-dienes may be removed by phenanthraquinone dehydrogenation²⁶ (scheme 4). However dehydrogenation of the methylstera-3,5-dienes **I** led to high proportions of non-demethylated products (33-91%). In order to evaluate the influence of additional methyl groups at position 2, 3 or 6 on the efficiency of C-19 demethylation, this reaction was tested with cholesta-3,5-diene **26**, prepared from cholesterol **19** by elimination of the *p*-toluenesulfonate **27**²⁷ in basic medium.²⁸ Dehydrogenation of cholesta-3,5-diene **26** gave only low proportions of non-demethylated products (0-7 %), thus suggesting that the presence of an additional methyl group on ring A or B hinders the removal of the C-19 methyl group.

After phenanthraquinone dehydrogenation²⁶ of **I**, the crude, a complex mixture of demethylated and non-demethylated polyenes, was treated with chloranil²⁶ affording octaenes **II** in low overall yields (1-6 %). Noteworthy, octaenes substituted with one chlorine atom were sometimes detected as by-products. The molecular structures of octaenes **II** were unambiguously assessed by ¹H-NMR with ¹H-¹H decoupling and nOe experiments. The 15,16 double bond of **II** was then hydrogenated²⁹ on Pd/C to give triaromatic steroid hydrocarbons **III**. This hydrogenation must be carefully followed by thin layer chromatography over silica gel impregnated with silver nitrate to avoid further hydrogenation. A good correlation is observed between ¹H-NMR chemical shifts of methyl groups at position 2 (**1**, 2.62 ppm), 3 (**2**, 2.56 ppm) or 6 (**3**, 2.76 ppm) and those of structurally homologous methylphenanthrenes:³⁰ 3-methylphenanthrene (2.62 ppm), 2-methylphenanthrene (2.56 ppm) and 9-methylphenanthrene (2.72 ppm), respectively.

EXPERIMENTAL

General

The reactions were followed by thin layer chromatography (TLC) on plates (10 cm) precoated with silicagel (0.25 mm) containing fluorescein. Silicagel-AgNO₃ plates were prepared by immersion of precoated plates in a solution of 10% silver nitrate in ethanol-water (3:1 v/v) for 45 s. After drying at room temperature (48 h), the plates were heated for 1 h at 120°C. The plates were developed by UV irradiation (254 nm, 365 nm), then immersion in sulfuric acid-ethanol (5%) and heating. Column chromatography (CC) was performed on silicagel (0.043-0.060 mm). Gas chromatography (GC): fused silica capillary column (30 m, 0.25 mm), phenyl(5%)-methylpolysiloxane phase (0.1 μm), flame ionization detector, H₂ carrier gas (2.5 ml/min.), 50-80°C at 25°/min then 80-300°C at 3°/min. The purity of products was checked by GC to be more than 98%, otherwise specified. Mass spectra were recorded on a gas chromatograph-mass spectrometer: GC conditions as above except He carrier gas (3.5 ml/min.), electronic impact (70 eV, otherwise specified), ion source 250°C. High performance liquid chromatography (HPLC): column (25 cm, 21.2 mm), octadecylsilane phase, methanol eluant (9 ml/min.), refractive index detector.

Elemental analyses (EA) were performed at the *service central de microanalyse du C.N.R.S. (division de Strasbourg)*. Melting points (mp) were determined on a heating microscope and are uncorrected. Nuclear magnetic resonance spectra of hydrogen nuclei (¹H-NMR) were recorded in CDCl₃ solutions at 200 MHz. Chemical shifts refer to the signal of tetramethylsilane (δ = 0 ppm) and were determined relative to the residual solvent peak (CHCl₃: δ = 7.27 ppm). Coupling constants (J) are measured in Hz. Coupling patterns are described by abbreviations: *s* (singlet), *d* (doublet), *t* (triplet) and *m* (multiplet). Steroids are named according to IUPAC-IUB rules.³¹
