L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# A GENERIC PROPERTY OF FAMILIES OF LAGRANGIAN SYSTEMS 

PATRICK BERNARD AND GONZALO CONTRERAS

#### Abstract

We prove that a generic lagrangian has finitely many minimizing measures for every cohomology class.

Annals of Maths, 167 No3. (2008).

## 1. Introduction

Let $M$ be a compact boundaryless smooth manifold.
Let $\mathbb{T}$ be either the group $(\mathbb{R} / \mathbb{Z},+)$ or the trivial group $(\{0\},+)$.
A Tonelli Lagrangian is a $C^{2}$ function $L: \mathbb{T} \times T M \rightarrow \mathbb{R}$ such that

- The restriction to each fiber of $\mathbb{T} \times T M \rightarrow \mathbb{T} \times M$ is a convex function.
- It is fiberwise superlinear:

$$
\lim _{|\theta| \rightarrow+\infty} L(t, \theta) /|\theta|=+\infty, \quad(t, \theta) \in \mathbb{T} \times T M
$$

- The Euler-Lagrange equation

$$
\frac{d}{d t} L_{v}=L_{x}
$$

defines a complete flow $\varphi: \mathbb{R} \times(\mathbb{T} \times T M) \longrightarrow \mathbb{T} \times T M$.
We say that a Tonelli Lagrangian $L$ is strong Tonelli if $L+u$ is a Tonelli Lagrangian for each $u \in C^{\infty}(\mathbb{T} \times M, \mathbb{R})$. When $\mathbb{T}=\{0\}$ we say that the lagrangian is autonomous.

Let $\mathcal{P}(L)$ be the set of Borel probability measures on $\mathbb{T} \times T M$ which are invariant under the Euler-Lagrange flow $\varphi$. The action functional $A_{L}: \mathcal{P}(L) \rightarrow \mathbb{R} \cup\{+\infty\}$ is defined as

$$
A_{L}(\mu):=\langle L, \mu\rangle:=\int_{\mathbb{T} \times T M} L d \mu
$$

The functional $A_{L}$ is lower semi-continuous and the minimizers of $A_{L}$ on $\mathcal{P}(L)$ are called minimizing measures. The ergodic components of a minimizing measure are also minimizing, and they are mutually singular, so that the set $\mathfrak{M}(L)$ of minimizing measures is a simplex whose extremal points are the ergodic minimizing measures.

In general, the simplex $\mathfrak{M}(L)$ may be of infinite dimension. The goal of the present paper is to prove that this is a very exceptional phenomenon. The first results in that direction were obtained by Mañé in (4). His paper has been very influential to our work.

[^0]We say that a property is generic in the sense of Mañé if, for each strong Tonelli Lagrangian $L$, there exists a residual subset $\mathcal{O} \subset C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ such that the property holds for all the Lagrangians $L-u, u \in \mathcal{O}$. A set is called residual if it is a countable intersection of open and dense sets. We recall which topology is used on $C^{\infty}(\mathbb{T} \times M, \mathbb{R})$. Denoting by $\|u\|_{k}$ the $C^{k}$-norm of a function $u: \mathbb{T} \times M \longrightarrow \mathbb{R}$, define

$$
\|u\|_{\infty}:=\sum_{k \in \mathbb{N}} \frac{\arctan \left(\|u\|_{k}\right)}{2^{k}} .
$$

Note that $\|.\|_{\infty}$ is not a norm. Endow the space $C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ with the translationinvariant metric $\|u-v\|_{\infty}$. This metric is complete, hence the Baire property holds: any residual subset of $C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ is dense.

Theorem 1. Let $A$ be a finite dimensional convex family of strong Tonelli Lagrangians. Then there exists a residual subset $\mathcal{O}$ of $C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ such that,

$$
u \in \mathcal{O}, \quad L \in A \quad \Longrightarrow \quad \operatorname{dim} \mathfrak{M}(L-u) \leqslant \operatorname{dim} A
$$

In other words, there exist at most $1+\operatorname{dim} A$ ergodic minimizing measures of $L-u$.
The main result of Mañé in [\#] is that having a unique minimizing measure is a generic property. This corresponds to the case where $A$ is a point in our statement. Our generalization of Mañe's result is motivated by the following construction due to John Mather:

We can view a 1 -form on $M$ as a function on $T M$ which is linear on the fibers. If $\lambda$ is closed, the Euler-Lagrange equation of the Lagrangian $L-\lambda$ is the same as that of $L$. However, the minimizing measures of $L-\lambda$, are not the same as the minimizing measures of $L$. Mather proves in [hat the set $\mathfrak{M}(L-\lambda)$ of minimizing measures of the lagrangian $L-\lambda$ depends only on the cohomology class $c$ of $\lambda$. If $c \in H^{1}(M, \mathbb{R})$ we write $\mathfrak{M}(L-c):=\mathfrak{M}(L-\lambda)$, where $\lambda$ is a closed form of cohomology $c$.

It turns out that important applications of Mather theory, such as the existence of orbits wandering in phase space, require understanding not only of the set $\mathfrak{M}(L)$ of minimizing measures for a fixed or generic cohomology classes but of the set of all Mather minimizing measures for every $c \in H^{1}(M, L)$. The following corollaries are crucial for these applications.

## Corollary 2. The following property is generic in the sense of Mañé:

For all $c \in H^{1}(M, \mathbb{R})$, there are at most $1+\operatorname{dim} H^{1}(M, \mathbb{R})$ ergodic minimizing measures of $L-c$.

We say that a property is of infinite codimension if, for each finite dimensional convex family $A$ of strong Tonelli Lagrangians, there exists a residual subset $\mathcal{O}$ in $C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ such that none of the Lagrangians $L-u, L \in A, u \in \mathcal{O}$ satisfy the property.

Corollary 3. The following property is of infinite codimension:
There exists $c \in H^{1}(M, \mathbb{R})$, such that $L-c$ has infinitely many ergodic minimizing measures.

Another important issue concerning variational methods for Arnold diffusion questions is the total disconnectedness of the quotient Aubry set. John Mather proves in [f, §3] that the quotient Aubry set $\overline{\mathcal{A}}$ of any Tonelli lagrangian on $\mathbb{T} \times T M$ with $\mathbb{T}=\mathbb{R} / \mathbb{Z}$ and $\operatorname{dim} M \leqslant 2$ (or with $\mathbb{T}=\{0\}$ and $\operatorname{dim} M \leqslant 3$ ) is totally disconnected. See $\mathbb{7}$ for its definition.

The elements of the quotient Aubry set are called static classes. They are disjoint subsets of $\mathbb{T} \times T M$ and each static class supports at least one ergodic minimizing measure. We then get

Corollary 4. The following property is generic in the sense of Mañé:
For all $c \in H^{1}(M, \mathbb{R})$ the quotient Aubry set $\overline{\mathcal{A}}_{c}$ of $L-c$ has at most $1+\operatorname{dim} H^{1}(M, \mathbb{R})$ elements.

## 2. Abstract Results

Assume that we are given

- Three topological vector spaces $E, F, G$.
- A continuous linear map $\pi: F \rightarrow G$.
- A bilinear pairing $\langle u, \nu\rangle: E \times G \rightarrow \mathbb{R}$.
- Two metrizable convex compact subsets $H \subset F$ and $K \subset G$ such that $\pi(H) \subset K$.

Suppose that
(i) The map

$$
E \times K \ni(u, \nu) \longmapsto\langle u, \nu\rangle
$$

is continuous.
We will also denote $\langle u, \pi(\mu)\rangle$ by $\langle u, \mu\rangle$ when $\mu \in H$. Observe that each element $u \in E$ gives rise to a linear functional on $F$

$$
F \ni \mu \longmapsto\langle u, \mu\rangle
$$

which is continuous on $H$. We shall denote by $H^{*}$ the set of affine and continuous functions on $H$ and use the same symbol $u$ for an element of $E$ and for the element $\mu \longmapsto\langle u, \mu\rangle$ of $H^{*}$ which is associated to it.
(ii) The compact $K$ is separated by $E$. This means that, if $\eta$ and $\nu$ are two different points of $K$, then there exists a point $u$ in $E$ such that $\langle u, \eta\rangle \neq\langle u, \nu\rangle$.

Note that the topology on $K$ is then the weak topology associated to $E$. A sequence $\eta_{n}$ of elements of $K$ converges to $\eta$ if and only if we have $\left\langle u, \eta_{n}\right\rangle \longrightarrow\langle u, \eta\rangle$ for each $u \in E$. We shall, for notational conveniences, fix once and for all a metric $d$ on $K$.
(iii) $E$ is a Frechet space. It means that $E$ is a topological vector space whose topology is defined by a translation-invariant metric, and that $E$ is complete for this metric.

Note then that $E$ has the Baire property. We say that a subset is residual if it is a countable intersection of open and dense sets. The Baire property says that any residual subset of $E$ is dense.
Given $L \in H^{*}$ denote by

$$
M_{H}(L):=\underset{H}{\arg \min } L
$$

the set of points $\mu \in H$ which minimize $\left.L\right|_{H}$, and by $M_{K}(L)$ the image $\pi\left(M_{H}(L)\right)$. These are compact convex subsets of $H$ and $K$.

Our main abstract result is:
Theorem 5. For every finite dimensional affine subspace $A$ of $H^{*}$, there exists a residual subset $\mathcal{O}(A) \subset E$ such that, for all $u \in \mathcal{O}(A)$ and all $L \in A$, we have

$$
\begin{equation*}
\operatorname{dim} M_{K}(L-u) \leq \operatorname{dim} A \tag{1}
\end{equation*}
$$

Proof: We define the $\varepsilon$-neighborhood $V_{\varepsilon}$ of a subset $V$ of $K$ as the union of all the open balls in $K$ which have radius $\varepsilon$ and are centered in $V$. Given a subset $D \subset A$, a positive number $\varepsilon$, and a positive integer $k$, denote by $\mathcal{O}(D, \varepsilon, k) \subset E$ the set of points $u \in E$ such that, for each $L \in D$, the convex set $M_{K}(L-u)$ is contained in the $\varepsilon$-neighborhood of some $k$-dimensional convex subset of $K$.

We shall prove that the theorem holds with

$$
\mathcal{O}(A)=\bigcap_{\varepsilon>0} \mathcal{O}(A, \varepsilon, \operatorname{dim} A)
$$

If $u$ belongs to $\mathcal{O}(A)$, then (11) holds for every $L \in A$. Otherwise, for some $L \in A$, the convex set $M_{K}(L-u)$ would contain a ball of dimension $\operatorname{dim} A+1$, and, if $\varepsilon$ is small enough, such a ball is not contained in the $\varepsilon$-neighborhood of any convex set of dimension $\operatorname{dim} A$.

So we have to prove that $\mathcal{O}(A)$ is residual. In view of the Baire property, it is enough to check that, for any compact subset $D \subset A$ and any positive $\varepsilon$, the set $\mathcal{O}(D, \varepsilon, \operatorname{dim} A)$ is open and dense. We shall prove in 2.1 that it is open, and in 2.2 that it is dense.

### 2.1. Open.

We prove that, for any $k \in \mathbb{Z}^{+}, \varepsilon>0$ and any compact $D \subset A$, the set $\mathcal{O}(D, \varepsilon, k) \subset E$ is open. We need a Lemma.

Lemma 6. The set-valued map $(L, u) \longmapsto M_{H}(L-u)$ is upper semi-continuous on $A \times E$. This means that for any open subset $U$ of $H$, the set

$$
\left\{(L, u) \in A \times E: M_{H}(L-u) \subset U\right\} \subset A \times E
$$

is open in $A \times E$. Consequently, the set-valued map $(L, u) \longmapsto M_{K}(L-u)$ is also upper semi-continuous.

Proof: This is a standard consequence of the continuity of the map

$$
A \times E \times H \ni(L, u, \mu) \longmapsto(L-u)(\mu)=L(\mu)-\langle u, \mu\rangle .
$$

Now let $u_{0}$ be a point of $\mathcal{O}(D, \varepsilon, k)$. For each $L \in D$, there exists a $k$-dimensional convex set $V \subset K$ such that $M_{K}\left(L-u_{0}\right) \subset V_{\varepsilon}$. In other words, the open sets of the form

$$
\left\{(L, u) \in D \times E: M_{H}(L-u) \subset V_{\varepsilon}\right\} \subset D \times E,
$$

where $V$ is some $k$-dimensional convex subset of $K$, cover the compact set $D \times\left\{u_{0}\right\}$. So there exists a finite subcovering of $D \times\left\{u_{0}\right\}$ by open sets of the form $\Omega_{i} \times U_{i}$, where $\Omega_{i}$ is an open set in $A$ and $U_{i} \subset \mathcal{O}\left(\Omega_{i}, \varepsilon, k\right)$ is an open set in $E$ containing $u_{0}$. We conclude that the open set $\cap U_{i}$ is contained in $\mathcal{O}(D, \varepsilon, k)$, and contains $u_{0}$. This ends the proof.

### 2.2. Dense.

We prove the density of $\mathcal{O}(A, \varepsilon, \operatorname{dim} A)$ in $E$ for $\varepsilon>0$. Let $w$ be a point in $E$. We want to prove that $w$ is in the closure of $\mathcal{O}(A, \varepsilon, \operatorname{dim} A)$.

Lemma 7. There exists an integer $m$ and a continuous map

$$
T_{m}=\left(w_{1}, \ldots, w_{m}\right): K \longrightarrow \mathbb{R}^{m},
$$

with $w_{i} \in E$ such that

$$
\begin{equation*}
\forall x \in \mathbb{R}^{m} \quad \operatorname{diam} T_{m}^{-1}(x)<\varepsilon, \tag{2}
\end{equation*}
$$

where the diameter is taken for the distance $d$ on $K$.
Proof: In $K \times K$, to each element $w \in E$ we associate the open set

$$
U_{w}=\{(\eta, \mu) \in K \times K:\langle w, \eta-\mu\rangle \neq 0\} .
$$

Since $E$ separates $K$, the open sets $U_{w}, w \in E$ cover the complement of the diagonal in $K \times K$. Since this complement is open in the separable metrizable set $K \times K$, we can extract a countable subcovering from this covering. So we have a sequence $U_{w_{k}}$, with $w_{k} \in E$, which covers the complement of the diagonal in $K \times K$. This amounts to say that the sequence $w_{k}$ separates $K$. Defining $T_{m}=\left(w_{1}, \ldots, w_{m}\right)$, we have to prove that (2) holds for $m$ large enough. Otherwise, we would have two sequences $\eta_{m}$ and $\mu_{m}$ in $K$ such that

$$
T_{m}\left(\mu_{m}\right)=T_{m}\left(\eta_{m}\right) \quad \text { and } \quad d\left(\mu_{m}, \eta_{m}\right) \geqslant \varepsilon .
$$

By extracting a subsequence, we can assume that the sequences $\mu_{m}$ and $\eta_{m}$ have different limits $\mu$ and $\eta$, which satisfy $d(\eta, \mu) \geqslant \varepsilon$. Take $m$ large enough, so that $T_{m}(\eta) \neq T_{m}(\mu)$. Such a value of $m$ exists because the linear forms $w_{k}$ separate $K$. We have that

$$
T_{m}\left(\mu_{k}\right)=T_{m}\left(\eta_{k}\right) \quad \text { for } \quad k \geq m .
$$

Hence at the limit $T_{m}(\eta)=T_{m}(\mu)$. This is a contradiction.

Define the function $F_{m}: A \times \mathbb{R}^{m} \rightarrow \mathbb{R} \cup\{+\infty\}$ as

$$
F_{m}(L, x):=\min _{\substack{\mu \in H \\ T_{m} \circ \pi(\mu)=x}}(L-w)(\mu)
$$

when $x \in T_{m}(\pi(H))$ and $F_{m}(L, x)=+\infty$ if $x \in \mathbb{R}^{m} \backslash T_{m}(\pi(H))$. For $y=\left(y_{1}, \ldots, y_{m}\right) \in \mathbb{R}^{m}$, let

$$
M_{m}(L, y):=\underset{x \in \mathbb{R}^{m}}{\arg \min }\left[F_{m}(L, x)-y \cdot x\right] \subset \mathbb{R}^{m}
$$

be the set of points which minimize the function $x \longmapsto F_{m}(L, x)-y \cdot x$. We have that

$$
M_{K}\left(L-w-y_{1} w_{1}-\cdots-y_{m} w_{m}\right) \subset T_{m}^{-1}\left(M_{m}(L, y)\right)
$$

Let

$$
\mathcal{O}_{m}(A, \operatorname{dim} A):=\left\{y \in \mathbb{R}^{m} \mid \forall L \in A: \operatorname{dim} M_{m}(L, y) \leqslant \operatorname{dim} A\right\}
$$

From Lemma $]^{7}$ it follows that

$$
y \in \mathcal{O}_{m}(A, \operatorname{dim} A) \quad \Longrightarrow \quad w+y_{1} w_{1}+\cdots+y_{m} w_{m} \in \mathcal{O}(A, \varepsilon, \operatorname{dim} A)
$$

Therefore, in order to prove that $w$ is in the closure of $\mathcal{O}(A, \varepsilon, \operatorname{dim} A)$, it is enough to prove that 0 is in the closure of $\mathcal{O}_{m}(A, \operatorname{dim} A)$, which follows from the next proposition.

Proposition 8. The set $\mathcal{O}_{m}(A, \operatorname{dim} A)$ is dense in $\mathbb{R}^{m}$.
Proof: Consider the Legendre transform of $F_{m}$ with respect to the second variable,

$$
\begin{aligned}
G_{m}(L, y) & =\max _{x \in \mathbb{R}^{m}} y \cdot x-F_{m}(L, x) \\
& =\max _{\mu \in H}\left\langle w+y_{1} w_{1}+\cdots+y_{m} w_{m}, \mu\right\rangle-L(\mu)
\end{aligned}
$$

It follows from this second expression that the function $G_{m}$ is convex and finite-valued, hence continuous on $A \times \mathbb{R}^{m}$.

Consider the set $\tilde{\Sigma} \subset A \times \mathbb{R}^{m}$ of points $(L, y)$ such that $\operatorname{dim} \partial G_{m}(L, y) \geq \operatorname{dim} A+1$, where $\partial G_{m}$ is the subdifferential of $G_{m}$. It is known, see the appendix, that this set has Hausdorff dimension at most

$$
(m+\operatorname{dim} A)-(\operatorname{dim} A+1)=m-1
$$

Consequently, the projection $\Sigma$ of the set $\tilde{\Sigma}$ on the second factor $\mathbb{R}^{m}$ also has Hausdorff dimension at most $m-1$. Therefore, the complement of $\Sigma$ is dense in $\mathbb{R}^{m}$. So it is enough to prove that

$$
y \notin \Sigma \quad \Longrightarrow \quad \forall L \in A: \quad \operatorname{dim} M_{m}(L, y) \leq \operatorname{dim} A
$$

Since we know by definition of $\Sigma$ that $\operatorname{dim} \partial G_{m}(L, y) \leq \operatorname{dim} A$, it is enough to observe that

$$
\operatorname{dim} M_{m}(L, y) \leq \operatorname{dim} \partial G_{m}(L, y)
$$

The last inequality follows from the fact that the set $M_{m}(L, y)$ is the subdifferential of the convex function

$$
\mathbb{R}^{m} \ni z \longmapsto G_{m}(L, z)
$$

at the point $y$.

## 3. Application to Lagrangian dynamics

Let $C$ be the set of continuous functions $f: \mathbb{T} \times T M \rightarrow \mathbb{R}$ with linear growth, i.e.

$$
\|f\|_{\ell}:=\sup _{(t, \theta) \in \mathbb{T} \times T M} \frac{|f(t, \theta)|}{1+|\theta|}<+\infty
$$

endowed with the norm $\|\cdot\|_{\ell}$.
We apply Theorem 5 to the following setting:

- $F=C^{*}$ is the vector space of continuous linear functionals $\mu: C \rightarrow \mathbb{R}$ provided with the weak-ᄎ topology. Recall that

$$
\lim _{n} \mu_{n}=\mu \quad \Longleftrightarrow \quad \lim _{n} \mu_{n}(f)=\mu(f), \quad \forall f \in C .
$$

- $E=C^{\infty}(\mathbb{T} \times M, \mathbb{R})$ provided with the $C^{\infty}$ topology.
- $G$ is the vector space of finite Borel signed measures on $\mathbb{T} \times M$, or equivalently the set of continuous linear forms on $C^{0}(\mathbb{T} \times M, \mathbb{R})$, provided with the weak- $\star$ topology.
- The pairing $E \times G \rightarrow \mathbb{R}$ is given by integration:

$$
\langle u, \nu\rangle=\int_{\mathbb{T} \times M} u d \nu
$$

- The continuous linear map $\pi: F \longrightarrow G$ is induced by the projection $\mathbb{T} \times T M \longrightarrow$ $\mathbb{T} \times M$.
- The compact $K \subset G$ is the set of Borel probability measures on $\mathbb{T} \times M$, provided with the weak-夫 topology. Observe that $K$ is separated by $E$.
- The compact $H_{n} \subset F$ is the set of holonomic probability measures which are supported on

$$
B_{n}:=\{(t, \theta) \in \mathbb{T} \times T M| | \theta \mid \leqslant n\} .
$$

Holonomic probabilities are defined as follows: Given a $C^{1}$ curve $\gamma: \mathbb{R} \rightarrow M$ of period $T \in \mathbb{N}$ define the element $\mu_{\gamma}$ of $F$ by

$$
\left\langle f, \mu_{\gamma}\right\rangle=\frac{1}{T} \int_{0}^{T} f(s, \gamma(s), \dot{\gamma}(s)) d s
$$

for each $f \in C$. Let

$$
\Gamma:=\left\{\mu_{\gamma} \mid \gamma \in C^{1}(\mathbb{R}, M) \text { is periodic of integral period }\right\} \subset F .
$$

The set $\mathcal{H}$ of holonomic probabilities is the closure of $\Gamma$ in $F$. One can see that $\mathcal{H}$ is convex (cf. Mañé 四, prop. 1.1(a)]). The elements $\mu$ of $\mathcal{H}$ satisfy $\langle 1, \mu\rangle=1$ therefore we have $\pi(\mathcal{H}) \subset K$.

Note that each Tonelli Lagrangian $L$ gives rise to an element of $H_{n}^{*}$.
Let $\mathfrak{M}(L)$ be the set of minimizing measures for $L$ and let $\operatorname{supp} \mathfrak{M}(L)$ be the union of their supports. Recalling that we have defined $M_{H_{n}}(L)$ as the set of measures $\mu \in H_{n}$ which minimize the action $\int L d \mu$ on $H_{n}$, we have:

Lemma 9. If $L$ is a Tonelli lagrangian then there exists $n \in \mathbb{N}$ such that

$$
\operatorname{dim} \pi\left(M_{H_{n}}(L)\right)=\operatorname{dim} \mathfrak{M}(L)
$$

## Proof:

Birkhoff theorem implies that $\mathfrak{M}(L) \subset \mathcal{H}$ (cf. Mañé [4, prop. 1.1.(b)]). In [5, Prop. 4, p. 185] Mather proves that $\operatorname{supp} \mathfrak{M}(L)$ is compact, therefore $\mathfrak{M}(L) \subset H_{n}$ for some $n \in \mathbb{N}$.

In [4, §1] Mañé proves that minimizing measures are also all the minimizers of the action functional $A_{L}(\mu)=\int L d \mu$ on the set of holonomic measures, therefore $\mathfrak{M}(L)=M_{H_{n}}(L)$ for some $n \in \mathbb{N}$.

In [5, Th. 2, p. 186] Mather proves that the restriction $\operatorname{supp} \mathfrak{M}(L) \rightarrow M$ of the projection $T M \rightarrow M$ is injective. Therefore the linear map $\pi: \mathfrak{M}(L) \rightarrow G$ is injective, so that $\operatorname{dim} \pi\left(M_{H_{n}}(L)\right)=\operatorname{dim} \pi(\mathfrak{M}(L))=\operatorname{dim} \mathfrak{M}(L)$.

## Proof of Theorem 1.

Given $n \in \mathbb{N}$ apply Theorem 5 and obtain a residual subset $\mathcal{O}_{n}(A) \subset E$ such that

$$
L \in A, \quad u \in \mathcal{O}_{n}(A) \Longrightarrow \quad \operatorname{dim} \pi\left(M_{H_{n}}(L-u)\right) \leqslant \operatorname{dim} A
$$

Let $\mathcal{O}(A)=\cap_{n} \mathcal{O}_{n}(A)$. By the Baire property $\mathcal{O}(A)$ is residual. We have that

$$
L \in A, \quad u \in \mathcal{O}(A), \quad n \in \mathbb{N} \Longrightarrow \quad \operatorname{dim} \pi\left(M_{H_{n}}(L-u)\right) \leqslant \operatorname{dim} A
$$

Then by Lemma 9, $\operatorname{dim} \mathfrak{M}(L-u) \leqslant \operatorname{dim} A$ for all $L \in A$ and all $u \in \mathcal{O}(A)$.

## Appendix A. Convex Functions

Given a convex function $f: \mathbb{R}^{n} \rightarrow \mathbb{R}$ and $x \in \mathbb{R}^{n}$, define its subdifferential as

$$
\partial f(x):=\left\{\ell: \mathbb{R}^{n} \rightarrow \mathbb{R} \text { linear } \mid f(y) \geqslant f(x)+\ell(y-x), \forall y \in \mathbb{R}^{n}\right\}
$$

Then the sets $\partial f(x) \subset \mathbb{R}^{n}$ are convex. If $k \in \mathbb{N}$, let

$$
\Sigma_{k}(f):=\left\{x \in \mathbb{R}^{n} \mid \operatorname{dim} \partial f(x) \geqslant k\right\} .
$$

The following result is standard.
Proposition 10. If $f: \mathbb{R}^{n} \rightarrow \mathbb{R}$ is a convex function then for all $0 \leqslant k \leqslant n$ the Hausdorff dimension $H D\left(\Sigma_{k}(f)\right) \leqslant n-k$.

We recall here an elegant proof due to Ambrosio and Alberti, see [1]. Note that much more can be said on the structure of $\Sigma_{k}$, see [2, 5] for example.

By adding $|x|^{2}$ if necessary (which does not change $\Sigma_{k}$ ) we can assume that $f$ is superlinear and that

$$
\begin{equation*}
f(y) \geqslant f(x)+\ell(y-x)+\frac{1}{2}|y-x|^{2} \quad \forall x, y \in \mathbb{R}^{n}, \quad \forall \ell \in \partial f(x) \tag{3}
\end{equation*}
$$

Lemma 11. $\quad \ell \in \partial f(x), \quad \ell^{\prime} \in \partial f\left(x^{\prime}\right) \quad \Longrightarrow \quad\left|x-x^{\prime}\right| \leqslant\left\|\ell-\ell^{\prime}\right\|$.

Proof: From inequality (3) we have that

$$
\begin{gathered}
f\left(x^{\prime}\right) \geqslant f(x)+\ell\left(x^{\prime}-x\right)+\frac{1}{2}\left|x^{\prime}-x\right|^{2} \\
f(x) \geqslant f\left(x^{\prime}\right)+\ell^{\prime}\left(x-x^{\prime}\right)+\frac{1}{2}\left|x-x^{\prime}\right|^{2}
\end{gathered}
$$

Then

$$
\begin{gather*}
0 \geqslant\left(\ell^{\prime}-\ell\right)\left(x-x^{\prime}\right)+\left|x-x^{\prime}\right|^{2}  \tag{4}\\
\left\|\ell-\ell^{\prime}\right\|\left|x-x^{\prime}\right| \geqslant\left(\ell-\ell^{\prime}\right)\left(x-x^{\prime}\right) \geqslant\left|x-x^{\prime}\right|^{2} \tag{5}
\end{gather*}
$$

Therefore $\left\|\ell-\ell^{\prime}\right\| \geqslant\left|x-x^{\prime}\right|$.
Since $f$ is superlinear, the subdifferential $\partial f$ is surjective and we have:
Corollary 12. There exists a Lipschitz function $F: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ such that

$$
\ell \in \partial f(x) \quad \Longrightarrow \quad x=F(\ell)
$$

## Proof of Proposition 10:

Let $A_{k}$ be a set with $H D\left(A_{k}\right)=n-k$ such that $A_{k}$ intersects any convex subset of dimension $k$. For example

$$
A_{k}=\left\{x \in \mathbb{R}^{n} \mid x \text { has at least } k \text { rational coordinates }\right\}
$$

Observe that

$$
x \in \Sigma_{k} \quad \Longrightarrow \quad \partial f(x) \text { intersects } A_{k} \quad \Longrightarrow \quad x \in F\left(A_{k}\right)
$$

Therefore $\Sigma_{k} \subset F\left(A_{k}\right)$. Since $F$ is Lipschitz, we have that $H D\left(\Sigma_{k}\right) \leqslant H D\left(A_{k}\right)=n-k$.
