## Abstract

We study the stability of finite difference schemes for hyperbolic initial boundary value problems in one space dimension. Assuming  $\ell^2$ -stability for the discretization of the hyperbolic operator as well as a geometric regularity condition, we show that an appropriate determinant condition, that is the analogue of the uniform Kreiss-Lopatinskii condition for the continuous problem, yields strong stability for the discretized initial boundary value problem. The analysis relies on a suitable *discrete block structure condition* and the construction of suitable symmetrizers. Our work extends the results of [9] to a wider class of finite difference schemes.

**AMS subject classification:** 65N12, 35L50.

**Keywords:** Hyperbolic systems, boundary conditions, finite difference schemes, stability, symmetrizers.

## 1 Introduction

The goal of this article is to make a precise study of the stability of finite difference schemes for hyperbolic initial boundary value problems in one space dimension. There has been a wide series of works on this subject, see e.g. [10, 18, 9, 5, 6] and the references therein. In the fundamental contribution [9], it was shown that strong stability of finite difference approximations is equivalent to an appropriate “determinant condition”, under the assumption that the discretization of the hyperbolic operator is either dissipative or unitary, see Assumption 5.4 in [9]. The determinant condition is the analogue of the uniform Kreiss-Lopatinskii condition for hyperbolic boundary value problems, see [11]. The results of [9] were extended to the multidimensional case in [16], assuming that the discretization of the hyperbolic operator is dissipative in the tangential directions. We also refer to [3] for a study of multidimensional finite volume approximations in the case of symmetric systems.

In one space dimension, the dissipativity assumption is not too restrictive though it may be not satisfied. As a matter of fact, many finite difference approximations of the equation:

$$\partial_t u + A \partial_x u = f, \quad (t, x) \in \mathbb{R}^+ \times \mathbb{R},$$

are dissipative under the assumption that 0 is not an eigenvalue of  $A$  and that the CFL condition is not satisfied in an optimal way. For initial boundary value problems on the half-line  $\{x > 0\}$ ,

this assumption on the matrix  $A$  means precisely that the boundary  $\{x = 0\}$  is noncharacteristic. In two space dimensions, the dissipativity assumption is much more restrictive (it is also much more difficult to check). In some cases, finite difference approximations of the equation:

$$\partial_t u + A_1 \partial_{x_1} u + A_2 \partial_{x_2} u = f, \quad (t, x_1, x_2) \in \mathbb{R}^+ \times \mathbb{R} \times \mathbb{R},$$

can be dissipative only if both  $A_1$  and  $A_2$  do not have 0 as an eigenvalue, which is far more restrictive than assuming that the boundary of the half-space  $\{x_2 > 0\}$  is non-characteristic. It is also rather restrictive from the point of view of applications (one can think of the linearized gas dynamics equations for instance).

The purpose of this article is therefore to extend the theory of [9] to the widest possible class of finite difference schemes. The reasons are twofold: first to cover as many applications as possible by diminishing the assumptions on the finite difference scheme, second to highlight the structural assumptions that are needed in the procedure to derive maximal energy estimates for the discretization of the initial boundary value problem. Our goal is also to avoid as much as possible using the specificities of hyperbolic systems in one space dimension so our results will be useful for a future extension to the multidimensional case. We shall give two examples of schemes that are covered by our results and that do not enter the framework of [9]. Let us now briefly recall the procedure to derive energy estimates for hyperbolic boundary value problems.

In the analysis of hyperbolic initial boundary value problems (both for continuous and discretized problems), energy estimates are based on two main steps. The first step consists in writing the problem as an “evolution” equation in the normal direction to the boundary, and in reducing the symbol of this evolution equation under a convenient form (that is usually called the block structure). Usually this evolution equation in the normal variable is not hyperbolic so the symbol can not be reduced to diagonal form. The second step of the analysis is to construct symmetrizers for this reduced form of the equations. The “compatibility” between the operator and the boundary conditions is encoded in a determinant condition, usually known as the uniform Kreiss-Lopatinskii condition. For the continuous problem, the block structure condition was proved by Kreiss [11] for strictly hyperbolic operators and non-characteristic boundary. Majda and Osher [12] observed that this condition is satisfied by many physical examples that are hyperbolic with constant multiplicity, both in the characteristic and non-characteristic case. The derivation of the determinant condition and the construction of symmetrizers were performed in [11]. Kreiss’s result was extended by Métivier [13] to hyperbolic operators with constant multiplicity (both for noncharacteristic and characteristic boundaries). Eventually, it was shown by Métivier and Zumbrun [15] that the block structure condition is equivalent to a geometric regularity property for the eigenvalues of the symbol associated with the Cauchy problem. The result in [15] characterizes completely the structural conditions on the hyperbolic operator that make the symmetrizers construction in [11] work.

Our goal is to extend the results of [15] to the “discrete” case. This requires first of all to define a suitable *discrete block structure condition*, then to show that geometric regularity of the eigenvalues of the symbol of the discretized hyperbolic operator is equivalent to the discrete block structure condition. The next step of the analysis is to construct symmetrizers and to prove maximal energy estimates. In the discrete case, the eigenvalues of the symbol of the discretized hyperbolic operator can have a more complex behavior than the eigenvalues of the symbol of the “continuous” hyperbolic operator. Consequently, we have less information on the diagonal blocks involved in the discrete block structure. We are then led to make some restrictions on the discretized hyperbolic operator that give some additional information on the blocks and allow us to construct a symmetrizer. We shall consider a wider class of schemes than those considered in [9]. As a matter of fact, the restrictions in [9] were such that the authors

could use the symmetrizers constructed in [11]. Weakening the assumptions of [9] requires to introduce a new type of symmetrizers. The construction of these new symmetrizers is performed here in details. We also improve the results of [9] by showing some refined results under weaker assumptions. Our new construction of symmetrizers is flexible enough to be generalized to even more general situations than what we consider here (the main problem is to find examples of more general situations but if such an example is found, there is no doubt that the symmetrizer construction can be adapted as explained below).

**Notations** In all this paper, we use the notations:

$$\begin{aligned}\mathcal{U} &:= \{\zeta \in \mathbb{C}, |\zeta| > 1\}, & \overline{\mathcal{U}} &:= \{\zeta \in \mathbb{C}, |\zeta| \geq 1\}, \\ \mathbb{D} &:= \{\zeta \in \mathbb{C}, |\zeta| < 1\}, & \mathbb{S}^1 &:= \{\zeta \in \mathbb{C}, |\zeta| = 1\}.\end{aligned}$$

We let  $\mathcal{M}_{p,N}(\mathbb{K})$  denote the set of  $p \times N$  matrices with entries in  $\mathbb{K} = \mathbb{R}$  or  $\mathbb{C}$ , and we use the notation  $\mathcal{M}_N(\mathbb{K})$  when  $p = N$ . If  $M \in \mathcal{M}_N(\mathbb{C})$ ,  $\text{sp}(M)$  denotes the spectrum of  $M$ , while  $M^*$  denotes the conjugate transpose of  $M$ . The real part of a matrix  $M$  is  $\text{Re } M := (M + M^*)/2$ . We let  $I$  denote the identity matrix, without mentioning the dimension. If  $H_1, H_2 \in \mathcal{M}_N(\mathbb{C})$  are two hermitian matrices, we write  $H_1 \geq H_2$  if for all  $x \in \mathbb{C}^N$  we have  $x^*(H_1 - H_2)x \geq 0$ . The norm of a vector  $x \in \mathbb{C}^N$  is  $|x| := (x^*x)^{1/2}$ . Eventually, we let  $\ell^2$  denote the set of square integrable sequences, without mentioning the indices of the sequences (sequences may be valued in  $\mathbb{C}^k$  for some integer  $k$ ).

## 2 Main results

We consider a hyperbolic initial boundary value problem in one space dimension:

$$\begin{cases} \partial_t u + A \partial_x u = F(t, x), & (t, x) \in \mathbb{R}^+ \times \mathbb{R}^+, \\ B u(t, 0) = g(t), & t \in \mathbb{R}^+, \\ u(0, x) = f(x), & x \in \mathbb{R}^+, \end{cases} \quad (1)$$

where  $A \in \mathcal{M}_N(\mathbb{R})$  is diagonalizable with real eigenvalues, and  $B \in \mathcal{M}_{N_+,N}(\mathbb{R})$  with  $N_+$  the number of positive eigenvalues of  $A$  (counted with their multiplicity). We assume that the boundary is noncharacteristic, that is  $0 \notin \text{sp}(A)$ . Problem (1) is well-posed in  $L^2$  if and only if:

$$\mathbb{R}^N = \text{Ker } B \oplus E_+(A),$$

where  $E_+(A)$  is the unstable eigenspace of  $A$  (associated with positive eigenvalues of  $A$ ). We introduce the finite difference approximation of (1). Let  $\Delta x, \Delta t > 0$  denote a space and a time step where  $\lambda = \Delta t / \Delta x$  is a fixed positive constant, and let  $p, q, r, s$  be some integers. For  $n \in \mathbb{N}$ , and  $j \in -r+1 + \mathbb{N}$ , we let  $U_j^n$  denote the approximation of the solution  $u$  to (1) on the rectangle  $[n \Delta t, (n+1) \Delta t] \times [j \Delta x, (j+1) \Delta x]$ . For  $j = -r+1, \dots, 0$ ,  $U_j^n$  approximates the trace  $u(n \Delta t, 0)$  on the boundary  $\{x = 0\}$ . The finite difference approximation of (1) reads:

$$\begin{cases} U_j^{n+1} = \sum_{\sigma=0}^s Q_\sigma U_j^{n-\sigma} + \Delta t F_j^n, & j \geq 1, \quad n \geq s, \\ U_j^{n+1} = \sum_{\sigma=-1}^s B_{j,\sigma} U_1^{n-\sigma} + g_j^n, & j = -r+1, \dots, 0, \quad n \geq s, \\ U_j^n = f_j^n, & j \geq -r+1, \quad n = 0, \dots, s, \end{cases} \quad (2)$$

where the operators  $Q_\sigma$  and  $B_{j,\sigma}$  are given by:

$$Q_\sigma := \sum_{\ell=-r}^p A_{\ell,\sigma} T^\ell, \quad B_{j,\sigma} := \sum_{\ell=0}^q B_{\ell,j,\sigma} T^\ell, \quad T^\ell U_k^m := U_{k+\ell}^m. \quad (3)$$

In (3), all matrices  $A_{\ell,\sigma}, B_{\ell,j,\sigma}$  belong to  $\mathcal{M}_N(\mathbb{R})$ . We recall the following definition from [9]:

**Definition 1** (Strong stability [9]). *The finite difference approximation (2) is said to be strongly stable if there exists a constant  $C$  such that for all  $\gamma > 0$  and all  $\Delta t \in ]0, 1]$ , the solution  $(U_j^n)$  of (2) with  $f_j^n = 0$  satisfies the estimate:*

$$\begin{aligned} & \frac{\gamma}{\gamma \Delta t + 1} \sum_{n \geq s} \sum_{j \geq -r+1} \Delta t \Delta x e^{-2\gamma n \Delta t} |U_j^n|^2 + \sum_{n \geq s} \sum_{j=-r+1}^0 \Delta t e^{-2\gamma n \Delta t} |U_j^n|^2 \\ & \leq C \left\{ \frac{\gamma \Delta t + 1}{\gamma} \sum_{n \geq s} \sum_{j \geq 1} \Delta t \Delta x e^{-2\gamma n \Delta t} |F_j^n|^2 + \sum_{n \geq s} \sum_{j=-r+1}^0 \Delta t e^{-2\gamma n \Delta t} |g_j^n|^2 \right\}. \end{aligned}$$

The estimate in definition 1 is the discrete counterpart of the maximal energy estimate for the ‘‘continuous’’ problem (1):

$$\begin{aligned} & \gamma \int_{\mathbb{R}^+ \times \mathbb{R}^+} e^{-2\gamma t} |u(t, x)|^2 dt dx + \int_{\mathbb{R}^+} e^{-2\gamma t} |u(t, 0)|^2 dt \\ & \leq C \left\{ \frac{1}{\gamma} \int_{\mathbb{R}^+ \times \mathbb{R}^+} e^{-2\gamma t} |F(t, x)|^2 dt dx + \int_{\mathbb{R}^+} e^{-2\gamma t} |g(t)|^2 dt \right\}. \end{aligned}$$

For later use, we introduce the symbol associated with the discretization of the hyperbolic operator:

$$\forall \kappa \in \mathbb{C} \setminus \{0\}, \quad \mathcal{A}(\kappa) := \begin{pmatrix} \widehat{Q}_0(\kappa) & \dots & \dots & \widehat{Q}_s(\kappa) \\ I & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ 0 & 0 & I & 0 \end{pmatrix} \in \mathcal{M}_{N(s+1)}(\mathbb{C}), \quad \widehat{Q}_\sigma(\kappa) := \sum_{\ell=-r}^p \kappa^\ell A_{\ell,\sigma}. \quad (4)$$

The uniform power boundedness of  $\mathcal{A}(\kappa)$  for  $\kappa \in \mathbb{S}^1$  is a necessary and sufficient condition to have  $\ell^2$ -stability for the discretized Cauchy problem, see for instance [4, chapter III.1] or [8, chapter 5]. This stability condition for the discretized Cauchy problem will play an important role in the stability analysis for the discretized initial boundary value problem (2), just like hyperbolicity plays an important role for the stability analysis of hyperbolic initial boundary value problems, see e.g. [11, 13, 15].

Let us now introduce the resolvent equation:

$$\begin{cases} w_j - \sum_{\sigma=0}^s z^{-\sigma-1} Q_\sigma w_j = F_j, & j \geq 1, \\ w_j - \sum_{\sigma=-1}^s z^{-\sigma-1} B_{j,\sigma} w_1 = g_j, & j = -r+1, \dots, 0, \end{cases} \quad (5)$$

where  $z \in \mathcal{U}$ ,  $(F_j) \in \ell^2$ , and  $g_{-r+1}, \dots, g_0 \in \mathbb{C}^N$ , that is obtained from (2) by applying a Laplace transform in time, see [9]. Then strong stability of (2) can be first characterized by an estimate on the resolvent equation:

**Proposition 1** ([9]). *The approximation (2) is strongly stable if and only if there exists a constant  $C > 0$  such that for all  $z \in \mathcal{U}$ , for all  $(F_j) \in \ell^2$ , and for all  $g_{-r+1}, \dots, g_0 \in \mathbb{C}^N$ , the resolvent equation (5) has a unique solution  $(w_j) \in \ell^2$  and this solution satisfies:*

$$\frac{|z|-1}{|z|} \sum_{j \geq -r+1} |w_j|^2 + \sum_{j=-r+1}^0 |w_j|^2 \leq C \left\{ \frac{|z|}{|z|-1} \sum_{j \geq 1} |F_j|^2 + \sum_{j=-r+1}^0 |g_j|^2 \right\}. \quad (6)$$

The goal of this article is to give necessary and/or sufficient conditions on the symbol (4) and on the boundary conditions in (2) so that the energy estimate (6) holds true, which implies strong stability in the sense of definition 1. As detailed in the introduction, it is convenient to rewrite the resolvent equation (5) as an “evolution” equation for the sequence  $(w_j)$ . For  $\ell = -r, \dots, p$ , we define the matrices:

$$\forall z \in \mathbb{C} \setminus \{0\}, \quad \mathbb{A}_\ell(z) := \delta_{\ell 0} I - \sum_{\sigma=0}^s z^{-\sigma-1} A_{\ell, \sigma}, \quad (7)$$

where  $\delta_{\ell_1 \ell_2}$  is the Kronecker symbol. Then as in [9], we make the following assumption:

**Assumption 1.** *The matrices  $\mathbb{A}_{-r}(z)$  and  $\mathbb{A}_p(z)$  are invertible for all  $z \in \overline{\mathcal{U}}$ , or equivalently for all  $z$  in some open neighborhood  $\mathcal{V}$  of  $\overline{\mathcal{U}}$ .*

As usual, it is convenient to rewrite the “multi-step” induction (5) as a “one-step” induction for an augmented vector. Assumption 1 is crucial to achieve this reduction.

We first consider the case  $q < p$ . In that case, all the  $w_j$ ’s involved in the “boundary conditions” for the resolvent equation (5) are coordinates of the augmented vector<sup>1</sup>  $W_1 := (w_p, \dots, w_{1-r})$ . Using assumption 1, we can define a matrix  $\mathbb{M}(z)$  that is holomorphic on some open neighborhood  $\mathcal{V}$  of  $\overline{\mathcal{U}}$ :

$$\forall z \in \mathcal{V}, \quad \mathbb{M}(z) := \begin{pmatrix} -\mathbb{A}_p(z)^{-1} \mathbb{A}_{p-1}(z) & \dots & \dots & -\mathbb{A}_p(z)^{-1} \mathbb{A}_{-r}(z) \\ I & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ 0 & 0 & I & 0 \end{pmatrix} \in \mathcal{M}_{N(p+r)}(\mathbb{C}). \quad (8)$$

Using the definition (3) for the operators  $Q_\sigma, B_{j, \sigma}$  and the matrix  $\mathbb{M}$ , we can rewrite the resolvent equation (5) as an induction relation for the augmented vector  $W_j := (w_{j+p-1}, \dots, w_{j-r})$ . This induction relation reads:

$$\begin{cases} W_{j+1} = \mathbb{M}(z) W_j + \widetilde{F}_j, & j \geq 1, \\ B(z) W_1 = g, \end{cases} \quad (9)$$

where the new source terms  $(\widetilde{F}_j), g$  in (9) are given by:

$$\widetilde{F}_j := (\mathbb{A}_p(z)^{-1} F_j, 0, \dots, 0), \quad g := (g_0, \dots, g_{1-r}).$$

It is easy to check that the matrix  $B(z) \in \mathcal{M}_{Nr, N(p+r)}$  depends holomorphically on  $z \in \mathbb{C} \setminus \{0\}$  and has maximal rank  $Nr$  for all  $z$ . The exact expression of the matrix  $B(z)$  can be easily obtained from (5) and (3) but is not very relevant here. The new resolvent equation (9) is of course equivalent to (5).

<sup>1</sup>Vectors are written indifferently in rows or columns to simplify the redaction.

Let us now treat the case  $q \geq p$ . In that case, we can still write the resolvent equation under the form (9) up to defining  $W_j := (w_{j+q}, \dots, w_{j-r})$ ,  $j \geq 1$ , and:

$$\mathbb{M}(z) := \begin{pmatrix} -\mathbb{A}_p(z)^{-1} \mathbb{A}_{p-1}(z) & \dots & -\mathbb{A}_p(z)^{-1} \mathbb{A}_{-r}(z) & 0 & \dots & 0 \\ I & 0 & \dots & \dots & 0 & 0 \\ 0 & 0 & \dots & \dots & 0 & 0 \\ 0 & 0 & \dots & 0 & I & 0 \end{pmatrix} \in \mathcal{M}_{N(q+r+1)}(\mathbb{C}).$$

The definition of  $B(z) \in \mathcal{M}_{Nr, N(q+r+1)}$  varies from the previous case but this matrix keeps a maximal rank  $Nr$  for all  $z$  and is still holomorphic on  $\mathbb{C} \setminus \{0\}$ . This equivalent form of the resolvent equation varies from what was done in [9]. In our approach, we can ensure that the matrix  $B(z)$  has maximal rank for all  $z \in \overline{\mathcal{U}}$ . This is important in view of the so-called uniform Kreiss-Lopatinskii condition assumed below in Theorem 2. This maximal rank property of  $B$  is not so clear if one uses the method in [9, page 672] when  $q \geq p$ . This is why we propose this alternative approach to rewrite the resolvent equation.

For simplicity, we shall deal from now on with the case  $q < p$  but our proofs can be extended in a straightforward way to the case  $q \geq p$ . Some intermediate results vary slightly but the method and arguments are the same in both cases.

Our goal is to prove an energy estimate for (9), which will yield an energy estimate for (5) and prove strong stability for the finite difference scheme (2) thanks to Proposition 1. We introduce the following terminology:

**Definition 2** (Discrete block structure condition). *Let  $M$  be a holomorphic function on some open neighborhood of  $\overline{\mathcal{U}}$  with values in  $\mathcal{M}_m(\mathbb{C})$  for some integer  $m$ . Then  $M$  is said to satisfy the discrete block structure condition if the two following conditions are satisfied:*

1. for all  $z \in \mathcal{U}$ ,  $\text{sp}(M(z)) \cap \mathbb{S}^1 = \emptyset$ ,
2. for all  $\underline{z} \in \overline{\mathcal{U}}$ , there exists an open neighborhood  $\mathcal{O}$  of  $\underline{z}$  in  $\mathbb{C}$ , and there exists an invertible matrix  $T(z)$  that is holomorphic with respect to  $z \in \mathcal{O}$  such that:

$$\forall z \in \mathcal{O}, \quad T(z)^{-1} M(z) T(z) = \text{diag} (M_1(z), \dots, M_L(z)),$$

where the number  $L$  of diagonal blocks and the size  $\nu_\ell$  of each block  $M_\ell$  do not depend on  $z \in \mathcal{O}$ , and where each block satisfies one of the following properties:

- there exists  $\delta > 0$  such that for all  $z \in \mathcal{O}$ ,  $M_\ell(z)^* M_\ell(z) \geq (1 + \delta) I$ ,
- there exists  $\delta > 0$  such that for all  $z \in \mathcal{O}$ ,  $M_\ell(z)^* M_\ell(z) \leq (1 - \delta) I$ ,
- $\nu_\ell = 1$ ,  $\underline{z}$  and  $M_\ell(\underline{z})$  belong to  $\mathbb{S}^1$ , and  $\underline{z} M'_\ell(\underline{z}) \overline{M_\ell(\underline{z})} \in \mathbb{R} \setminus \{0\}$ ,
- $\nu_\ell > 1$ ,  $\underline{z} \in \mathbb{S}^1$  and  $M_\ell(\underline{z})$  has the form:

$$M_\ell(\underline{z}) = \underline{\kappa}_\ell \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 1 \\ 0 & \dots & 0 & 1 \end{pmatrix}, \quad \underline{\kappa}_\ell \in \mathbb{S}^1.$$

Moreover the lower left coefficient  $m_\ell$  of  $M'_\ell(\underline{z})$  is such that for all  $\sigma \in \mathbb{C}$  with  $\text{Re } \sigma > 0$ , and for all complex number  $\zeta$  such that  $\zeta^{\nu_\ell} = \overline{\underline{\kappa}_\ell} m_\ell \underline{z} \sigma$ , then  $\text{Re } \zeta \neq 0$ .

We refer to the blocks  $M_\ell$  as being of the first, second, third or fourth type.

The discrete block structure condition is more precise than the normal form of [9, Theorem 9.1]. Definition 2 clarifies the structure of the blocks associated with eigenvalues in  $\mathbb{S}^1$ . Such blocks are either scalar, which was not clear in [9], or have a Jordan structure. This clarification will simplify the construction of symmetrizers.

Our first main result gives necessary and sufficient conditions on the symbol  $\mathcal{A}$  so that the matrix  $\mathbb{M}$  defined by (8) satisfies the discrete block structure condition:

**Theorem 1.** *Let assumption 1 be satisfied. Then  $\mathbb{M}$  defined by (8) satisfies the discrete block structure condition if and only if the symbol  $\mathcal{A}$  defined by (4) satisfies the two following conditions:*

- *there exists a constant  $C > 0$  such that for all  $\kappa \in \mathbb{S}^1$  and all  $n \in \mathbb{N}$ ,  $\|\mathcal{A}(\kappa)^n\| \leq C$ ,*
- *if  $\underline{\kappa} \in \mathbb{S}^1$  and  $\underline{z} \in \mathbb{S}^1 \cap \text{sp}(\mathcal{A}(\underline{\kappa}))$  has algebraic multiplicity  $\underline{\alpha}$ , then there exist some functions  $\lambda_1(\kappa), \dots, \lambda_{\underline{\alpha}}(\kappa)$  that are holomorphic in a neighborhood  $\mathcal{W}$  of  $\underline{\kappa}$  in  $\mathbb{C}$ , such that:*

$$\begin{aligned} \lambda_1(\underline{\kappa}) &= \dots = \lambda_{\underline{\alpha}}(\underline{\kappa}) = \underline{z}, \\ \det(zI - \mathcal{A}(\kappa)) &= \vartheta(\kappa, z) \prod_{j=1}^{\underline{\alpha}} (z - \lambda_j(\kappa)), \end{aligned} \tag{10}$$

*with  $\vartheta$  a holomorphic function of  $(\kappa, z)$  in some neighborhood of  $(\underline{\kappa}, \underline{z})$  in  $\mathbb{C}^2$  such that  $\vartheta(\underline{\kappa}, \underline{z}) \neq 0$ , and there exist some vectors  $E_1(\kappa), \dots, E_{\underline{\alpha}}(\kappa) \in \mathbb{C}^{N(s+1)}$  that are holomorphic with respect to  $\kappa \in \mathcal{W}$ , that are linearly independent for all  $\kappa \in \mathcal{W}$ , and that satisfy:*

$$\forall \kappa \in \mathcal{W}, \quad \forall j = 1, \dots, \underline{\alpha}, \quad \mathcal{A}(\kappa) E_j(\kappa) = \lambda_j(\kappa) E_j(\kappa).$$

Theorem 1 shows that  $\mathbb{M}$  satisfies the discrete block structure condition if and only if the discretization of the hyperbolic operator is  $\ell^2$ -stable and moreover the eigenvalues of the symbol  $\mathcal{A}$  that belong to the unit circle are geometrically regular. No geometric regularity is required for eigenvalues in  $\mathbb{D}$ . Theorem 1 is the analogue for finite difference schemes of Theorem C.3 in [15]. The assumptions of Theorem 1 allow more general situations than the cases covered by [9]. In particular, we show that assumptions 5.2 and 5.3 in [9] are not necessary to reduce  $\mathbb{M}$  to the discrete block structure. Let us make the following:

**Remark 1.** *We recall that the geometric regularity of the eigenvalues in  $\mathbb{S}^1$  is not a consequence of the uniform power boundedness of  $\{\mathcal{A}(\kappa), \kappa \in \mathbb{S}^1\}$ . For instance the following matrix:*

$$\begin{pmatrix} 1 + \Upsilon(\kappa) & \Upsilon(\kappa) \\ 0 & 1 + \Upsilon(\kappa) \end{pmatrix}, \quad \Upsilon(\kappa) := \frac{(\kappa - \kappa^{-1})^2}{4},$$

*is holomorphic with respect to  $\kappa \in \mathbb{C} \setminus \{0\}$ , and is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ . However 1 is not a geometrically regular eigenvalue for  $\kappa = 1$ .*

The reduction of  $\mathbb{M}$  to the discrete block structure is a crucial step towards proving energy estimates as we shall see below. It is indeed easier to construct symmetrizers for each block rather than directly constructing a symmetrizer for the whole matrix  $\mathbb{M}$ .

In what follows, we are going to give sufficient conditions on the symbol  $\mathcal{A}$  and on the boundary conditions in (2) that yield strong stability. Unfortunately, our structural conditions on  $\mathcal{A}$  are more restrictive than the conditions in Theorem 1 that ensure the discrete block condition for  $\mathbb{M}$ . However we shall allow more general situations than what was considered in [9]. We shall also give some examples of new situations where our analysis applies.

Let us introduce the following terminology that is inspired from [14]:

**Definition 3** (*K*-symmetrizer). *Let assumption 1 be satisfied, and let  $\mathbb{M}$  be defined by (8). Then  $\mathbb{M}$  is said to admit a *K*-symmetrizer if for all  $\underline{z} \in \overline{\mathcal{U}}$ , there exists a decomposition:*

$$\mathbb{C}^{N(p+r)} = \mathbb{E}^s \oplus \mathbb{E}^u, \quad \dim \mathbb{E}^s = Nr, \quad \dim \mathbb{E}^u = Np,$$

*with associated projectors  $(\underline{\pi}^s, \underline{\pi}^u)$ , such that for all  $K \geq 1$ , there exists a neighborhood  $\mathcal{O}$  of  $\underline{z}$  in  $\mathbb{C}$ , there exists a  $\mathcal{C}^\infty$  function  $S$  on  $\mathcal{O}$  with values in  $\mathcal{M}_{N(p+r)}(\mathbb{C})$ , and there exists a constant  $c > 0$  such that the following properties hold for all  $z \in \mathcal{O} \cap \overline{\mathcal{U}}$ :*

- $S(z)$  is hermitian,
- $\mathbb{M}(z)^* S(z) \mathbb{M}(z) - S(z) \geq c(|z| - 1)/|z| I$ ,
- for all  $W \in \mathbb{C}^{N(p+r)}$ ,  $W^* S(z) W \geq K^2 |\underline{\pi}^u W|^2 - |\underline{\pi}^s W|^2$ .

Before going on, we make the following:

**Remark 2.** *In definition 3, the neighborhood  $\mathcal{O}$ , the mapping  $S$  and the constant  $c$  heavily depend on  $K$ . What is important is that the decomposition of  $\mathbb{C}^{N(p+r)}$  only depends on the point  $\underline{z}$  that is considered.*

*If  $\underline{z} \in \mathcal{U}$ , the first estimate in definition 3 is equivalent to proving that  $\mathbb{M}(\underline{z})^* S(\underline{z}) \mathbb{M}(\underline{z}) - S(\underline{z})$  is positive definite.*

*The last estimate in definition 3 can be deduced from the estimate:*

$$\forall W \in \mathbb{C}^{N(p+r)}, \quad W^* S(\underline{z}) W \geq \left(K^2 + \frac{1}{2}\right) |\underline{\pi}^u W|^2 - \frac{1}{2} |\underline{\pi}^s W|^2.$$

*This reduces the third point to a verification only at the point  $\underline{z}$ . We shall repeatedly use this property in our construction of *K*-symmetrizers.*

Our second main result gives sufficient conditions for strong stability of (2) and is the following:

**Theorem 2.** *Let assumption 1 be satisfied. Assume that the symbol  $\mathcal{A}(\kappa)$  defined by (4) is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ , and that  $\mathbb{M}$  defined by (8) admits a *K*-symmetrizer. For  $z \in \mathcal{U}$ , we let  $\mathbb{E}^s(z)$  denote the generalized eigenspace associated with eigenvalues of  $\mathbb{M}(z)$  in  $\mathbb{D}$ . Then  $\mathbb{E}^s(z)$  has constant dimension  $Nr$  for all  $z \in \mathcal{U}$  and  $\mathbb{E}^s$  defines a holomorphic vector bundle over  $\mathcal{U}$  that can be extended in a unique way as a continuous vector bundle over  $\overline{\mathcal{U}}$ . We let  $\mathbb{E}^s(z)$  denote this continuous extension for  $z \in \mathbb{S}^1 (= \partial\mathcal{U})$ .*

*In addition to all assumptions above, assume that for all  $z \in \overline{\mathcal{U}}$  we have  $\mathbb{E}^s(z) \cap \text{Ker } B(z) = \{0\}$ . (In what follows this condition is referred to as the uniform Kreiss-Lopatinskii condition.) Then the scheme (2) is strongly stable.*

Theorem 2 reduces the verification of the strong stability of (2) to *i*) constructing a suitable symmetrizer for  $\mathbb{M}$  in the neighborhood of any point  $\underline{z} \in \overline{\mathcal{U}}$ , and *ii*) verifying the so-called uniform Kreiss-Lopatinskii condition. This condition may be formulated as a *determinant condition* provided that we choose a basis of  $\mathbb{E}^s(z)$  and a basis of  $\text{Ker } B(z)$ . Point *i*) is usually performed by first reducing  $\mathbb{M}$  to the discrete block structure, and this is where Theorem 1 is useful. The verification of the uniform Kreiss-Lopatinskii condition may be quite involved since it requires to compute the continuous extension of  $\mathbb{E}^s$  to  $\overline{\mathcal{U}}$ . For low order schemes where  $r$  is small, the computations may be performed with no major difficulty, see e.g. [9, section 6]; however the verification becomes really complicated for high order schemes with large  $r$ . Nevertheless, one

may try a numerical verification of this condition, as indicated in [8, chapter 13]. The continuous extension of  $\mathbb{E}^s(z)$  to  $z \in \overline{\mathcal{W}}$  is not explicitly proved in [9] though it is crucially needed in the formulation of the so-called determinant condition.

Our last main result gives sufficient conditions for the existence of a  $K$ -symmetrizer. Combined with the result of Theorem 2 above, Theorem 3 below thus gives sufficient conditions for strong stability of (2).

**Theorem 3.** *Let assumption 1 be satisfied, and assume that the symbol  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ . Assume moreover that all the eigenvalues of  $\mathcal{A}(\kappa)$ ,  $\kappa \in \mathbb{S}^1$ , that belong to  $\mathbb{S}^1$  are geometrically regular and that at least one of the three following properties is satisfied by each eigenvalue  $\lambda_j(\kappa)$  in the decomposition (10):*

- i)  $\lambda_j'(\underline{\kappa}) \neq 0$ ,
- ii)  $\lambda_j(\kappa) \in \mathbb{S}^1$  for all  $\kappa \in \mathbb{S}^1 \cap \mathcal{W}$ ,
- iii)  $\operatorname{Re}(\underline{\kappa}^2 \overline{\lambda_j(\underline{\kappa})} \lambda_j''(\underline{\kappa})) > 0$ .

*Then  $\mathbb{M}$  defined by (8) admits a  $K$ -symmetrizer. In particular, if the uniform Kreiss-Lopatinskii condition is satisfied, the scheme (2) is strongly stable.*

The rest of this paper is devoted to the proofs of Theorems 1, 2 and 3. In section 6 we shall detail some examples of schemes for which our analysis applies. This section includes new examples that were not covered by the analysis of [9]. Appendices A and B are devoted to the proof of intermediate results that are used in the proofs of the main Theorems. Eventually, appendix C is devoted to an extension of Theorem 3 where we consider even more general situations. The purpose of appendix C is to convince the reader that our new construction of symmetrizers can be adapted to any situation where we make a dissipation type assumption for the eigenvalues  $\lambda_j$ .

Possible generalizations of our results are detailed in the following:

**Remark 3.** *A possible generalization of Theorem 2 is to show that the vector bundle  $\mathbb{E}^s$  can be continuously extended to  $\overline{\mathcal{W}}$  assuming only that the discrete block structure condition is satisfied by  $\mathbb{M}$ . This would allow to define the uniform Kreiss-Lopatinskii condition as in Theorem 2 for a wider class of numerical schemes. However, checking the uniform Kreiss-Lopatinskii condition is useless if one is not also able to construct symmetrizers. In our work, extending continuously the bundle  $\mathbb{E}^s$  to  $\overline{\mathcal{W}}$  appears as a consequence of the symmetrizers construction, even though it may be already hidden in the discrete block structure condition.*

*Our construction of symmetrizers is smooth with respect to the frequency  $z$ . We thus have all the ingredients for an extension of our results to variable coefficients difference operators. The only new ingredient that is needed is a suitable quantification for pseudo-difference operators, see e.g. [16, section 4].*

*Eventually, our results generalize the theory in [9] so we can extend to our more general framework some previous results that were based on the results of [9], see e.g. [5, 6, 7] for simplified stability criteria or convergence estimates. Since we have not used the specificities of the one-dimensional framework, our analysis can be a good starting point for a generalization of Michelson's results [16] in several space dimensions. This is left to a future work.*

### 3 Proof of Theorem 1

Let us recall that we assume  $q < p$  for simplicity. We first assume that the symbol  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$  and that its eigenvalues that belong to the unit circle  $\mathbb{S}^1$  are geometrically regular. We are going to show that  $\mathbb{M}$  satisfies the discrete block structure condition. Recall that  $\mathbb{M}$  is holomorphic on an open neighborhood  $\mathcal{V}$  of  $\overline{\mathcal{U}}$ , see (8). We first recall a classical Lemma:

**Lemma 1** ([9]). *Let assumption 1 be satisfied and assume that  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ . Then for all  $z \in \mathcal{V}$ , the eigenvalues of  $\mathbb{M}(z)$  are those  $\kappa \in \mathbb{C} \setminus \{0\}$  such that:*

$$\det(\mathcal{A}(\kappa) - zI) = 0.$$

*In particular for all  $z \in \mathcal{U}$ ,  $\mathbb{M}(z)$  has no eigenvalue on the unit circle  $\mathbb{S}^1$  and the number of eigenvalues in  $\mathbb{D}$  equals  $Nr$  (eigenvalues are counted with their algebraic multiplicity).*

Lemma 1 shows that the first condition in definition 2 is satisfied. Furthermore, this property immediately implies that the discrete block structure condition is satisfied in the neighborhood of any  $\underline{z} \in \mathcal{U}$ . More precisely, in a small neighborhood  $\mathcal{O}$  of  $\underline{z} \in \mathcal{U}$ , the generalized eigenspace associated with eigenvalues of  $\mathbb{M}(z)$  in  $\mathbb{D}$  and the generalized eigenspace associated with eigenvalues of  $\mathbb{M}(z)$  in  $\mathcal{U}$  both depend holomorphically on  $z \in \mathcal{O}$ . We can then reduce  $\mathbb{M}(z)$  to a block diagonal form:

$$T(z)^{-1} \mathbb{M}(z) T(z) = \text{diag}(\mathbb{M}_b(z), \mathbb{M}_\#(z)), \quad \mathbb{M}_b(z) \in \mathcal{M}_{Nr}(\mathbb{C}), \quad \mathbb{M}_\#(z) \in \mathcal{M}_{Np}(\mathbb{C}),$$

where the eigenvalues of  $\mathbb{M}_b(z)$  belong to  $\mathbb{D}$  and the eigenvalues of  $\mathbb{M}_\#(z)$  belong to  $\mathcal{U}$ . The change of basis  $T(z)$  depends holomorphically on  $z \in \mathcal{O}$ . Up to a constant change of basis, we can achieve the inequalities:

$$\mathbb{M}_b(\underline{z})^* \mathbb{M}_b(\underline{z}) \leq (1 - 2\delta)I, \quad \mathbb{M}_\#(\underline{z})^* \mathbb{M}_\#(\underline{z}) \geq (1 + 2\delta)I,$$

with  $\delta$  some positive constant. Thanks to a continuity argument, we can conclude that the discrete block structure condition is satisfied in a neighborhood of  $\underline{z}$ . The reduction only involves blocks of the first and second type.

We now turn to the case  $\underline{z} \in \mathbb{S}^1$ . If  $\mathbb{M}(\underline{z})$  has no eigenvalue in  $\mathbb{S}^1$  then we are reduced to the preceding case. We thus assume that  $\mathbb{M}(\underline{z})$  has some eigenvalues in  $\mathbb{S}^1$ . More precisely, let  $\underline{\kappa}_1, \dots, \underline{\kappa}_k$  denote the elements of  $\text{sp}(\mathbb{M}(\underline{z})) \cap \mathbb{S}^1$ . We also let  $\alpha_1, \dots, \alpha_k$  denote the algebraic multiplicity of these eigenvalues. The generalized eigenspace  $\text{Ker}(\mathbb{M}(\underline{z}) - \underline{\kappa}_j I)^{\alpha_j}$  associated with  $\underline{\kappa}_j$  is denoted  $\mathbb{K}_j$ . For  $z$  sufficiently close to  $\underline{z}$ , we also let  $\mathbb{K}_j(z)$  denote the generalized eigenspace of  $\mathbb{M}(z)$  associated with its  $\alpha_j$  eigenvalues that are close to  $\underline{\kappa}_j$ . The space  $\mathbb{K}_j(z)$  depends holomorphically on  $z$ . Then for  $z$  in a small neighborhood  $\mathcal{O}$  of  $\underline{z}$ , we can perform a block diagonalization of  $\mathbb{M}(z)$  with a holomorphic change of basis:

$$T(z)^{-1} \mathbb{M}(z) T(z) = \text{diag}(\mathbb{M}_b(z), \mathbb{M}_\#(z), \mathbb{M}_1(z), \dots, \mathbb{M}_k(z)),$$

where the eigenvalues of  $\mathbb{M}_b(z)$  belong to  $\mathbb{D}$ , the eigenvalues of  $\mathbb{M}_\#(z)$  belong to  $\mathcal{U}$ , and for all  $j = 1, \dots, k$  the  $\alpha_j$  eigenvalues of  $\mathbb{M}_j(z)$  belong to a sufficiently small neighborhood of  $\underline{\kappa}_j$ . As in the preceding case, we can easily achieve the inequalities:

$$\forall z \in \mathcal{O}, \quad \mathbb{M}_b(z)^* \mathbb{M}_b(z) \leq (1 - \delta)I, \quad \mathbb{M}_\#(z)^* \mathbb{M}_\#(z) \geq (1 + \delta)I,$$

so from now on we focus on the blocks  $\mathbb{M}_j(z)$ . For the sake of clarity, we shall only deal with the block  $\mathbb{M}_1(z)$ . This is only to avoid overloaded notations with many indices. Of course, the analysis below is valid for any of the blocks  $\mathbb{M}_j(z)$ . We are going to show that in a convenient holomorphic basis of  $\mathbb{K}_1(z)$ , the block  $\mathbb{M}_1(z)$  reduces to a block diagonal form with blocks of the third and fourth types. The proof follows the analysis of [13, 15] and splits in several steps.

• Following [13], we first study the characteristic polynomial of  $\mathbb{M}_1(z)$ . For  $z$  close to  $\underline{z}$ , the  $\alpha_1$  eigenvalues of  $\mathbb{M}_1(z)$  are close to  $\underline{\kappa}_1$ . A standard computation shows that for all  $z \in \mathcal{V}$  and all  $\kappa \in \mathbb{C} \setminus \{0\}$ , we have<sup>2</sup>:

$$\det(\mathbb{M}(z) - \kappa I) = \vartheta(\kappa, z) \det(zI - \mathcal{A}(\kappa)), \quad (11)$$

where  $\vartheta$  is holomorphic with respect to  $(\kappa, z)$  and does not vanish on  $\mathbb{C} \setminus \{0\} \times \mathcal{V}$ . We thus obtain:

$$\det(\mathbb{M}_1(z) - \kappa I) = \vartheta(\kappa, z) \det(zI - \mathcal{A}(\kappa)), \quad (12)$$

where  $\vartheta$  is holomorphic with respect to  $(\kappa, z)$  and does not vanish on a small neighborhood of  $(\underline{\kappa}_1, \underline{z})$ . The generic notation  $\vartheta$  is used for a nonvanishing holomorphic function that may vary from one line to the other. We know that  $\underline{z} \in \mathbb{S}^1$  is an eigenvalue of  $\mathcal{A}(\underline{\kappa}_1)$  so we can use the geometric regularity assumption. For  $(\kappa, z)$  in a sufficiently small neighborhood of  $(\underline{\kappa}_1, \underline{z})$ , (12) reads:

$$\det(\mathbb{M}_1(z) - \kappa I) = \vartheta(\kappa, z) \prod_{j=1}^{\underline{\alpha}} (z - \lambda_j(\kappa)), \quad (13)$$

where  $\underline{\alpha}$  is a fixed integer, and the  $\lambda_j$ 's are holomorphic functions on a neighborhood  $\mathcal{W}$  of  $\underline{\kappa}_1$  and satisfy  $\lambda_j(\underline{\kappa}_1) = \underline{z}$ . Thanks to the uniform power boundedness of the matrices  $\mathcal{A}(\kappa)$  for  $\kappa \in \mathbb{S}^1$ , we know that  $|\lambda_j(\kappa)| \leq 1$  for  $\kappa \in \mathbb{S}^1 \cap \mathcal{W}$ . Using a Taylor expansion of  $\lambda_j(\underline{\kappa}_1 e^{i\xi})$  for  $\xi \in \mathbb{R}$  close to 0, we obtain that there exists a real number  $\alpha_j$  such that:

$$\underline{\kappa}_1 \lambda_j'(\underline{\kappa}_1) = \alpha_j \underline{z}, \quad \alpha_j \in \mathbb{R}. \quad (14)$$

Thanks to (13), we can see that  $\underline{\kappa}_1$  is a root with finite multiplicity  $\nu_j$  of the holomorphic function  $\underline{z} - \lambda_j(\cdot)$ :

$$\forall \nu = 1, \dots, \nu_j - 1, \quad \lambda_j^{(\nu)}(\underline{\kappa}_1) = 0, \quad \lambda_j^{(\nu_j)}(\underline{\kappa}_1) \neq 0. \quad (15)$$

We can therefore apply the Weierstrass preparation Theorem to the holomorphic function  $z - \lambda_j(\kappa)$ : for all  $j = 1, \dots, \underline{\alpha}$ , there exists  $P_j(\kappa, z)$  that is a unitary polynomial function in  $\kappa$  with degree  $\nu_j$ , such that for  $(\kappa, z)$  close to  $(\underline{\kappa}_1, \underline{z})$ :

$$z - \lambda_j(\kappa) = \vartheta(\kappa, z) P_j(\kappa, z), \quad P_j(\kappa, \underline{z}) = (\kappa - \underline{\kappa}_1)^{\nu_j}, \quad \vartheta(\underline{\kappa}_1, \underline{z}) \neq 0. \quad (16)$$

Using (16), (13) reduces to:

$$\det(\mathbb{M}_1(z) - \kappa I) = \vartheta(\kappa, z) \prod_{j=1}^{\underline{\alpha}} P_j(\kappa, z). \quad (17)$$

For  $z$  close to  $\underline{z}$ , the polynomial  $P_j(\cdot, z)$  has  $\nu_j$  roots close to  $\underline{\kappa}_1$ . Consequently, the size of the block  $\mathbb{M}_1(z)$  equals  $\nu_1 + \dots + \nu_{\underline{\alpha}}$ . We also know that the size of this block equals  $\alpha_1$ , the algebraic multiplicity of the eigenvalue  $\underline{\kappa}_1$ . Up to reordering the terms, there exists an integer  $\underline{\beta}$  such that:

$$\nu_1 = \dots = \nu_{\underline{\beta}} = 1, \quad \nu_{\underline{\beta}+1}, \dots, \nu_{\underline{\alpha}} \geq 2.$$

---

<sup>2</sup>This relation is a little stronger than the result recalled in Lemma 1, but it can be obtained by applying standard computation rules for determinants.

For  $j = 1, \dots, \underline{\beta}$ , we know that  $\lambda'_j(\underline{\kappa}_1) \neq 0$  or equivalently  $\alpha_j \neq 0$  in (14). Therefore  $\lambda_j$  is a biholomorphic homeomorphism from a neighborhood  $\mathscr{W}$  of  $\underline{\kappa}_1$  to a neighborhood  $\mathscr{O}$  of  $\underline{z}$ . We let  $\mu_j$  denote its (holomorphic) inverse. With such notations, we obtain  $P_j(\kappa, z) = \kappa - \mu_j(z)$  for all  $j = 1, \dots, \underline{\beta}$ .

Using the relation (16), we also obtain  $\partial_z P_j(\underline{\kappa}_1, \underline{z}) \neq 0$ . Then Puiseux's expansions theory shows that for  $z$  close to  $\underline{z}$  and  $z \neq \underline{z}$ , the  $\nu_j$  roots of  $P_j(\cdot, z)$  are simple, see for instance [1].

• For each eigenvalue  $\lambda_j(\kappa)$ ,  $j = 1, \dots, \underline{\alpha}$  and  $\kappa$  close to  $\underline{\kappa}_1$ , we know that  $\mathscr{A}(\kappa)$  has a holomorphic eigenvector  $E_j(\kappa) \in \mathbb{C}^{N(s+1)}$ . Using the definition (4) of  $\mathscr{A}$ , we find that  $E_j(\kappa)$  can be written as:

$$\forall j = 1, \dots, \underline{\alpha}, \quad E_j(\kappa) = \begin{pmatrix} \lambda_j(\kappa)^s e_j(\kappa) \\ \vdots \\ \lambda_j(\kappa) e_j(\kappa) \\ e_j(\kappa) \end{pmatrix}, \quad e_j(\kappa) \in \mathbb{C}^N.$$

The vectors  $e_1(\underline{\kappa}_1), \dots, e_{\underline{\alpha}}(\underline{\kappa}_1)$  are linearly independent in  $\mathbb{C}^N$  because  $E_1(\underline{\kappa}_1), \dots, E_{\underline{\alpha}}(\underline{\kappa}_1)$  are linearly independent in  $\mathbb{C}^{N(s+1)}$ . Therefore when  $\kappa$  is close to  $\underline{\kappa}_1$ , the vectors  $e_1(\kappa), \dots, e_{\underline{\alpha}}(\kappa)$  remain linearly independent. We define the following vectors:

$$\forall j = 1, \dots, \underline{\alpha}, \quad \mathscr{E}_j(\kappa) := \begin{pmatrix} \kappa^{p+r-1} e_j(\kappa) \\ \vdots \\ \kappa e_j(\kappa) \\ e_j(\kappa) \end{pmatrix} \in \mathbb{C}^{N(p+r)}.$$

These vectors depend holomorphically on  $\kappa$ , and they are linearly independent for  $\kappa$  close to  $\underline{\kappa}_1$ . Using the relations (7) and (8), some straightforward computations show that  $\mathscr{E}_j(\kappa)$  is an eigenvector of the matrix  $\mathbb{M}(\lambda_j(\kappa))$  associated with the eigenvalue  $\kappa$ :

$$\forall j = 1, \dots, \underline{\alpha}, \quad (\mathbb{M}(\lambda_j(\kappa)) - \kappa I) \mathscr{E}_j(\kappa) = 0. \quad (18)$$

In particular, for  $j = 1, \dots, \underline{\beta}$  and for  $z$  in a neighborhood  $\mathscr{O}$  of  $\underline{z}$ , we have:

$$\forall j = 1, \dots, \underline{\beta}, \quad \forall z \in \mathscr{O}, \quad (\mathbb{M}(z) - \mu_j(z) I) \mathscr{E}_j(\mu_j(z)) = 0. \quad (19)$$

Recall that  $\mu_j$  is the holomorphic inverse of  $\lambda_j$  for  $j = 1, \dots, \underline{\beta}$ , that is when  $\lambda'_j(\underline{\kappa}_1) \neq 0$ . For all  $j = 1, \dots, \underline{\beta}$ , we have thus constructed a holomorphic eigenvalue  $\mu_j(z)$  and a holomorphic eigenvector  $\mathscr{E}_j(\mu_j(z))$  of  $\mathbb{M}(z)$ . Moreover, we have  $\mu'_j(\underline{z}) = 1/\lambda'_j(\underline{\kappa}_1)$  so we get:

$$\forall j = 1, \dots, \underline{\beta}, \quad \mu_j(\underline{z}) = \underline{\kappa}_1 \in \mathbb{S}^1, \quad \underline{z} \mu'_j(\underline{z}) \overline{\mu_j(\underline{z})} = \frac{1}{\alpha_j} \in \mathbb{R} \setminus \{0\}.$$

• We now turn to the most difficult case  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ . We start from (18), differentiate this relation  $\nu_j - 1$  times with respect to  $\kappa$ , and evaluate the result at  $\kappa = \underline{\kappa}_1$ :

$$\begin{aligned} & (\mathbb{M}(\underline{z}) - \underline{\kappa}_1 I) \mathscr{E}_j(\underline{\kappa}_1) = 0, \\ & - \mathscr{E}_j(\underline{\kappa}_1) + (\mathbb{M}(\underline{z}) - \underline{\kappa}_1 I) \mathscr{E}'_j(\underline{\kappa}_1) = 0, \\ & \quad \vdots \\ & - (\nu_j - 1) \mathscr{E}_j^{(\nu_j-2)}(\underline{\kappa}_1) + (\mathbb{M}(\underline{z}) - \underline{\kappa}_1 I) \mathscr{E}_j^{(\nu_j-1)}(\underline{\kappa}_1) = 0. \end{aligned}$$

Then for all  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ , we define the following vectors:

$$(\underline{\mathcal{E}}_{j,1}, \dots, \underline{\mathcal{E}}_{j,\nu_j}) := \left( \mathcal{E}_j(\underline{\kappa}_1), \frac{\underline{\kappa}_1}{1!} \mathcal{E}'_j(\underline{\kappa}_1), \dots, \frac{\underline{\kappa}_1^{\nu_j-1}}{(\nu_j-1)!} \mathcal{E}_j^{(\nu_j-1)}(\underline{\kappa}_1) \right), \quad (20)$$

that satisfy the relations:

$$(\mathbb{M}(z) - \underline{\kappa}_1 I) \underline{\mathcal{E}}_{j,1} = 0, \quad \forall \mu = 2, \dots, \nu_j, \quad (\mathbb{M}(z) - \underline{\kappa}_1 I) \underline{\mathcal{E}}_{j,\mu} = \underline{\kappa}_1 \underline{\mathcal{E}}_{j,\mu-1}. \quad (21)$$

Using the relations (19) and (21), we can show as in [13, 15] that the vectors:

$$\underline{\mathcal{E}}_1(\underline{\kappa}_1), \dots, \underline{\mathcal{E}}_{\underline{\beta}}(\underline{\kappa}_1), \quad \underline{\mathcal{E}}_{\underline{\beta}+1,1}, \dots, \underline{\mathcal{E}}_{\underline{\beta}+1,\nu_{\underline{\beta}+1}}, \quad \dots, \quad \underline{\mathcal{E}}_{\underline{\alpha},1}, \dots, \underline{\mathcal{E}}_{\underline{\alpha},\nu_{\underline{\alpha}}},$$

are linearly independent. Moreover, these  $\alpha_1$  vectors span the generalized eigenspace  $\mathbb{K}_1$  of  $\mathbb{M}(\underline{z})$  associated with the eigenvalue  $\underline{\kappa}_1$ . So far we have thus obtained a basis of  $\mathbb{K}_1$  in which the block  $\mathbb{M}_1(z)$  reads:

$$\mathbb{M}_1(z) = \text{diag} \left( \underline{\kappa}_1, \dots, \underline{\kappa}_1, \underline{M}_{\underline{\beta}+1}, \dots, \underline{M}_{\underline{\alpha}} \right), \quad \underline{M}_j := \underline{\kappa}_1 \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 1 \\ 0 & \dots & 0 & 1 \end{pmatrix} \in \mathcal{M}_{\nu_j}(\mathbb{C}).$$

In the final step of the analysis, we are going to extend the definition of the vectors  $\underline{\mathcal{E}}_{j,\mu}$  to a neighborhood of  $\underline{z}$ . The proof follows the arguments of [13].

• Let us recall that for all  $j = 1, \dots, \underline{\alpha}$ , the polynomial  $P_j$  is defined by (16). We can choose  $r > 0$  such that for  $z$  in a neighborhood  $\mathcal{O}$  of  $\underline{z}$ , the  $\nu_j$  roots of  $P_j(\cdot, z)$  belong to the disc of center  $\underline{\kappa}_1$  and radius  $r/2$ . Then for all  $z \in \mathcal{O}$ , for all  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$  and for all  $\mu = 1, \dots, \nu_j$ , we define a vector  $\underline{\mathcal{E}}_{j,\mu}(z)$  by the following formula:

$$\underline{\mathcal{E}}_{j,\mu}(z) := \frac{\underline{\kappa}_1^{\mu-1} (\nu_j - \mu)!}{2i\pi \nu_j!} \int_{|\kappa - \underline{\kappa}_1| = r} \frac{\partial_\kappa^\mu P_j(\kappa, z)}{P_j(\kappa, z)} \underline{\mathcal{E}}_j(\kappa) d\kappa.$$

Cauchy's formula shows that for  $z = \underline{z}$ ,  $\underline{\mathcal{E}}_{j,\mu}(\underline{z})$  coincides with the vector  $\underline{\mathcal{E}}_{j,\mu}$  defined by (20). Moreover,  $\underline{\mathcal{E}}_{j,\mu}(z)$  depends holomorphically on  $z \in \mathcal{O}$ . Consequently we can choose the neighborhood  $\mathcal{O}$  such that for all  $z \in \mathcal{O}$ , the vectors:

$$\underline{\mathcal{E}}_1(\mu_1(z)), \dots, \underline{\mathcal{E}}_{\underline{\beta}}(\mu_{\underline{\beta}}(z)), \quad \underline{\mathcal{E}}_{\underline{\beta}+1,1}(z), \dots, \underline{\mathcal{E}}_{\underline{\beta}+1,\nu_{\underline{\beta}+1}}(z), \quad \dots, \quad \underline{\mathcal{E}}_{\underline{\alpha},1}(z), \dots, \underline{\mathcal{E}}_{\underline{\alpha},\nu_{\underline{\alpha}}}(z), \quad (22)$$

are linearly independent. We are going to show that these vectors span the invariant subspace  $\mathbb{K}_1(z)$ , and that in this basis of  $\mathbb{K}_1(z)$ , the matrix  $\mathbb{M}_1(z)$  is in block diagonal form with blocks of the third and fourth type.

We follow [13]: for  $z$  close to  $\underline{z}$  and  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ , we let  $\mathbb{F}_j(z)$  denote the vector space spanned by the linearly independent vectors  $\underline{\mathcal{E}}_{j,1}(z), \dots, \underline{\mathcal{E}}_{j,\nu_j}(z)$ . For  $j = 1, \dots, \underline{\beta}$ , we let  $\mathbb{F}_j(z)$  denote the one-dimensional vector space spanned by  $\underline{\mathcal{E}}_j(\mu_j(z))$ . Then for all  $j$ , the dimension of  $\mathbb{F}_j(z)$  is  $\nu_j$ . Moreover the sum of the  $\mathbb{F}_j(z)$  is direct and has dimension  $\alpha_1$ . We already know that for  $j = 1, \dots, \underline{\beta}$ ,  $\underline{\mathcal{E}}_j(\mu_j(z))$  is an eigenvector of  $\mathbb{M}(z)$  for the eigenvalue  $\mu_j(z)$ , see (19). Consequently,  $\mathbb{F}_j(z)$  is stable by the matrix  $\mathbb{M}(z)$  and  $\mathbb{F}_j(z) \subset \mathbb{K}_1(z)$  for  $j = 1, \dots, \underline{\beta}$ . We are now going to show that the same properties hold true for  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ . For  $z = \underline{z}$ , thanks to (21), we know that  $\mathbb{F}_j(\underline{z})$  is stable by  $\mathbb{M}(\underline{z})$  and  $\mathbb{F}_j(\underline{z}) \subset \mathbb{K}_1$ . From now on we thus consider a fixed  $z \in \mathcal{O} \setminus \{\underline{z}\}$ .

For all  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ , we let  $\kappa_{j,1}, \dots, \kappa_{j,\nu_j}$  denote the  $\nu_j$  distinct roots of the polynomial  $P_j(\cdot, z)$ . These roots belong to the disc of center  $\underline{\kappa}_1$  and radius  $r/2$ . Therefore, using the residue Theorem, we obtain:

$$\mathcal{E}_{j,\mu}(z) = \sum_{m=1}^{\nu_j} \omega_{j,\mu,m} \mathcal{E}_j(\kappa_{j,m}),$$

for some suitable complex numbers  $\omega_{j,\mu,m}$ . Therefore  $\mathbb{F}_j(z)$  is contained in the vector space  $\widetilde{\mathbb{F}}_j(z)$  spanned by the vectors  $\mathcal{E}_j(\kappa_{j,1}), \dots, \mathcal{E}_j(\kappa_{j,\nu_j})$ . Because the dimension of  $\mathbb{F}_j(z)$  is  $\nu_j$ , we can conclude that the dimension of  $\widetilde{\mathbb{F}}_j(z)$  is also  $\nu_j$  and  $\mathbb{F}_j(z) = \widetilde{\mathbb{F}}_j(z)$ . Let us now show that  $\widetilde{\mathbb{F}}_j(z)$  is stable by  $\mathbb{M}(z)$ . We know that  $P_j(\kappa_{j,m}, z) = 0$  so  $z = \lambda_j(\kappa_{j,m})$ . Using (18) we see that  $\mathcal{E}_j(\kappa_{j,m})$  is an eigenvector of  $\mathbb{M}(z)$  for the eigenvalue  $\kappa_{j,m}$  that is close to  $\underline{\kappa}_1$ . Consequently the vector space  $\widetilde{\mathbb{F}}_j(z)$  is stable by  $\mathbb{M}(z)$  and  $\widetilde{\mathbb{F}}_j(z) \subset \mathbb{K}_1(z)$ . Since  $\mathbb{F}_j(z) = \widetilde{\mathbb{F}}_j(z)$ , we have proved that for all  $j = 1, \dots, \underline{\alpha}$ ,  $\mathbb{F}_j(z)$  is stable by  $\mathbb{M}(z)$  and  $\mathbb{F}_j(z) \subset \mathbb{K}_1(z)$ . Using a dimension argument, we have obtained:

$$\mathbb{K}_1(z) = \mathbb{F}_1(z) \oplus \dots \oplus \mathbb{F}_{\underline{\alpha}}(z),$$

and each  $\mathbb{F}_j(z)$  is a stable vector space for  $\mathbb{M}(z)$ . Moreover, the characteristic polynomial of the restriction of  $\mathbb{M}(z)$  to  $\mathbb{F}_j(z)$  is  $P_j(\cdot, z)$ . We have thus constructed a holomorphic basis of  $\mathbb{K}_1(z)$  in which the matrix  $\mathbb{M}_1(z)$  reads:

$$\mathbb{M}_1(z) = \text{diag} (\mu_1(z), \dots, \mu_{\underline{\beta}}(z), M_{\underline{\beta}+1}(z), \dots, M_{\underline{\alpha}}(z)).$$

We also know that the characteristic polynomial of  $M_j(z)$  is  $P_j(\cdot, z)$  for  $j = \underline{\beta} + 1, \dots, \underline{\alpha}$ , and  $M_j(z)$  is the Jordan block  $\underline{M}_j$  defined above.

• The only remaining task is to obtain the property stated in definition 2 for the lower left corner coefficient  $m_j$  of  $M'_j(z)$ . We know that  $P_j(\kappa, z)$  is the characteristic polynomial of  $M_j(z)$ . Computing the derivative of  $\det(M_j(z) - \underline{\kappa}_1 I)$  with respect to  $z$  and evaluating at  $z = \underline{z}$ , we obtain  $m_j \neq 0$  (because  $\partial_z P_j(\underline{\kappa}_1, \underline{z}) \neq 0$ ). We can then compute the first term in the Puiseux expansion of the eigenvalues of  $M_j(z)$  as in [9] (we refer the reader to [1] for a complete justification of the Puiseux expansions for the eigenvalues of  $M_j(z)$ ). Following [9, page 676], the conclusion on  $m_j$  follows from the following estimate:

**Lemma 2** ([9]). *Let  $\mathcal{A}(\kappa)$  be uniformly power bounded for  $\kappa \in \mathbb{S}^1$  and let assumption 1 be satisfied. Then there exists a constant  $C > 0$  such that for all  $z \in \mathcal{U}$  and for all  $\kappa \in \mathbb{S}^1$ , we have:*

$$\|(\mathbb{M}(z) - \kappa I)^{-1}\| \leq C \frac{|z|}{|z| - 1}.$$

We give an alternate elementary proof of Lemma 2 in appendix A. Our proof relies on very simple algebraic computations and does not use the arguments of [9].

So far we have proved that the uniform power boundedness of  $\{\mathcal{A}(\kappa), \kappa \in \mathbb{S}^1\}$  and the geometric regularity of its eigenvalues in  $\mathbb{S}^1$  imply the discrete block structure for  $\mathbb{M}$ . From now on, we wish to prove the converse and therefore assume that  $\mathbb{M}$  satisfies the discrete block structure assumption. The proof follows [15, appendix C]. First of all, relation (11) shows that for all  $\kappa \in \mathbb{S}^1$ , the eigenvalues of  $\mathcal{A}(\kappa)$  lie in  $\overline{\mathbb{D}}$ . We are first going to show that the eigenvalues of  $\mathcal{A}(\kappa)$  that belong to  $\mathbb{S}^1$  are geometrically regular. Then we shall show that  $\mathcal{A}(\kappa)$  is uniformly power bounded. We have the following:

**Lemma 3.** *Let  $\mathcal{F} := \{\kappa \in \mathbb{S}^1, \text{sp}(\mathcal{A}(\kappa)) \cap \mathbb{S}^1 \neq \emptyset\}$ . Then  $\mathcal{F}$  is a closed subset of  $\mathbb{S}^1$ .*

We omit the proof of this Lemma that easily follows from a compactness argument. Let  $\underline{\kappa} \in \mathcal{F}$ , and let  $\underline{z} \in \text{sp}(\mathcal{A}(\underline{\kappa})) \cap \mathbb{S}^1$  have algebraic multiplicity  $\underline{\alpha}$ . Using relation (11), we know that  $\underline{\kappa}$  is an eigenvalue of  $\mathbb{M}(\underline{z})$ . Because  $\mathbb{M}$  satisfies the discrete block structure condition, we know that there exists a neighborhood  $\mathcal{O}$  of  $\underline{z}$  and a holomorphic change of basis  $T(z)$  for  $z \in \mathcal{O}$  such that:

$$T(z)^{-1} \mathbb{M}(z) T(z) = \text{diag} (\mathbb{M}_1(z), \dots, \mathbb{M}_{L'}(z), \mathbb{M}_{L'+1}(z), \dots, \mathbb{M}_L(z)),$$

where for all  $\ell = 1, \dots, L'$ ,  $\underline{\kappa} \in \text{sp}(\mathbb{M}_\ell(\underline{z}))$  and for all  $\ell \geq L' + 1$ ,  $\underline{\kappa} \notin \text{sp}(\mathbb{M}_\ell(\underline{z}))$ . Since  $\underline{\kappa} \in \mathbb{S}^1$ ,  $\mathbb{M}_\ell$  is necessarily a block of the third or fourth type<sup>3</sup> for all  $\ell = 1, \dots, L'$ . Consequently the spectrum of  $\mathbb{M}_\ell(\underline{z})$  is reduced to  $\{\underline{\kappa}\}$  for  $\ell = 1, \dots, L'$ . For all  $\ell = 1, \dots, L'$  and  $z \in \mathcal{O}$ , we define:

$$P_\ell(\kappa, z) = \det(\mathbb{M}_\ell(z) - \kappa I).$$

We clearly have:

$$\det(\mathbb{M}(z) - \kappa I) = \vartheta(\kappa, z) \prod_{\ell=1}^{L'} P_\ell(\kappa, z), \quad \vartheta(\underline{\kappa}, \underline{z}) \neq 0.$$

Using the relation (11), we obtain:

$$\det(z I - \mathcal{A}(\kappa)) = \vartheta(\kappa, z) \prod_{\ell=1}^{L'} P_\ell(\kappa, z), \quad \vartheta(\underline{\kappa}, \underline{z}) \neq 0,$$

and  $\vartheta$  is holomorphic with respect to  $(\kappa, z)$  in a neighborhood of  $(\underline{\kappa}, \underline{z})$ . Using the discrete block structure condition, we also have  $\partial_z P_\ell(\underline{\kappa}, \underline{z}) \neq 0$  because  $\mathbb{M}_\ell$  is a block of the third or fourth type. Applying the Weierstrass preparation Theorem to  $P_\ell$ , there exists a holomorphic function  $\lambda_\ell$  defined on a neighborhood  $\mathcal{W}$  of  $\underline{\kappa}$  such that:

$$P_\ell(\kappa, z) = \vartheta(\kappa, z) (z - \lambda_\ell(\kappa)), \quad \lambda_\ell(\underline{\kappa}) = \underline{z}, \quad \vartheta(\underline{\kappa}, \underline{z}) \neq 0.$$

We have thus obtained the factorization:

$$\det(z I - \mathcal{A}(\kappa)) = \vartheta(\kappa, z) \prod_{\ell=1}^{L'} (z - \lambda_\ell(\kappa)), \quad \vartheta(\underline{\kappa}, \underline{z}) \neq 0.$$

In particular, this shows that  $L'$  is the algebraic multiplicity  $\underline{\alpha}$  of  $\underline{z}$  as an eigenvalue of  $\mathcal{A}(\underline{\kappa})$ .

We know that  $\mathbb{M}_\ell(\lambda_\ell(\kappa)) - \kappa I$  has a nontrivial kernel for all  $\kappa$  close to  $\underline{\kappa}$  and  $\ell = 1, \dots, L'$ . Following [15], we can show that this kernel has dimension 1 for all  $\kappa$ , and is spanned by some vector that can be chosen holomorphically with respect to  $\kappa$ . We can therefore construct some vectors  $\mathcal{E}_1(\kappa), \dots, \mathcal{E}_{L'}(\kappa)$  that depend holomorphically on  $\kappa$ , that are linearly independent for all  $\kappa \in \mathcal{W}$ , and that satisfy:

$$\forall \ell = 1, \dots, L', \quad (\mathbb{M}(\lambda_\ell(\kappa)) - \kappa I) \mathcal{E}_\ell(\kappa) = 0.$$

Using some previous computations, the existence of such vectors  $\mathcal{E}_\ell(\kappa)$  yields the existence of vectors  $E_1(\kappa), \dots, E_{L'}(\kappa) \in \mathbb{C}^{N(s+1)}$  that depend holomorphically on  $\kappa$ , and that satisfy:

$$\forall \ell = 1, \dots, L', \quad (\mathcal{A}(\kappa) - \lambda_\ell(\kappa) I) E_\ell(\kappa) = 0.$$

We have thus proved that  $\underline{z}$  is a geometrically regular eigenvalue of  $\mathcal{A}(\underline{\kappa})$ .

---

<sup>3</sup>Blocks of the first and second type have no eigenvalue in  $\mathbb{S}^1$ .

It remains to show that  $\mathcal{A}(\kappa)$  is uniformly power bounded. For all  $\underline{\kappa} \in \mathcal{F}$ , we have shown that there exists a neighborhood  $\mathcal{W}$  of  $\underline{\kappa}$  in  $\mathbb{C}$ , and there exists a holomorphic change of basis  $Q(\kappa)$  such that:

$$\forall \kappa \in \mathcal{W}, \quad Q(\kappa)^{-1} \mathcal{A}(\kappa) Q(\kappa) = \text{diag} (\lambda_1(\kappa), \dots, \lambda_L(\kappa), \mathcal{A}_b(\kappa)),$$

where  $\lambda_1(\kappa), \dots, \lambda_L(\kappa)$  are complex numbers that satisfy  $\lambda_j(\underline{\kappa}) \in \mathbb{S}^1$ , and  $\mathcal{A}_b(\kappa)$  is a block whose eigenvalues belong to  $\mathbb{D}$  for all  $\kappa \in \mathcal{W}$ . There is no restriction in assuming that  $\mathcal{W}$  is open, that  $Q(\kappa)$  and  $Q(\kappa)^{-1}$  are uniformly bounded on  $\mathcal{W}$ , and that the spectrum of  $\mathcal{A}_b(\kappa)$  is uniformly bounded away from  $\mathbb{S}^1$  for  $\kappa \in \mathcal{W}$ .

Since  $\mathcal{F}$  is compact, we can use a finite covering of  $\mathcal{F}$  by such neighborhoods  $\mathcal{W}_1, \dots, \mathcal{W}_k$ . For all  $\kappa \in \mathbb{S}^1 \cap \mathcal{W}_i$ , the eigenvalues  $\lambda_1(\kappa), \dots, \lambda_{L_i}(\kappa)$  belong to  $\mathbb{D} \cup \mathbb{S}^1$ . Moreover, there exists a constant  $\delta > 0$  such that for all  $\kappa \in \mathcal{W}_i$ , the eigenvalues of  $\mathcal{A}_b(\kappa)$  have a modulus bounded by  $1 - \delta$ . Using also a uniform bound for  $T_i(\kappa)$  and  $T_i(\kappa)^{-1}$ , we can conclude that there exists a constant  $C > 0$  such that:

$$\forall \kappa \in \mathbb{S}^1 \cap \cup_i \mathcal{W}_i, \quad \forall n \in \mathbb{N}, \quad \|\mathcal{A}(\kappa)^n\| \leq C.$$

For  $\kappa$  in the closed subset  $(\mathbb{S}^1 \setminus \cup_i \mathcal{W}_i)$  of  $\mathbb{S}^1$ , we know that the spectrum of  $\mathcal{A}(\kappa)$  lies inside  $\mathbb{D}$ . Consequently, there exists a constant  $\delta > 0$  such that for all  $\kappa \in (\mathbb{S}^1 \setminus \cup_i \mathcal{W}_i)$ , the eigenvalues of  $\mathcal{A}(\kappa)$  have a modulus bounded by  $1 - \delta$ . This shows that there exists a constant  $C > 0$  such that:

$$\forall \kappa \in \mathbb{S}^1 \setminus \cup_i \mathcal{W}_i, \quad \forall n \in \mathbb{N}, \quad \|\mathcal{A}(\kappa)^n\| \leq C.$$

The matrix  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ , and the proof of Theorem 1 is complete.

## 4 Proof of Theorem 2

Let assumption 1 be satisfied, and assume that  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ . Then Lemma 1 shows that the “stable” subspace  $\mathbb{E}^s(z)$  of  $\mathbb{M}(z)$  has constant dimension  $Nr$  for all  $z \in \mathcal{U}$ . The holomorphic dependance of  $\mathbb{M}(z)$  on  $z$  implies that  $\mathbb{E}^s(z)$  also varies holomorphically with  $z$  on  $\mathcal{U}$ , see e.g. [1].

Let  $\underline{z} \in \mathbb{S}^1$  and let us show that  $\mathbb{E}^s(z)$  has a limit as  $z \in \mathcal{U}$  tends to  $\underline{z}$ . Let  $K > 2$ , and let us consider the decomposition  $\mathbb{C}^{N(p+r)} = \underline{\mathbb{E}}^s \oplus \underline{\mathbb{E}}^u$  as well as the neighborhood  $\mathcal{O}$  and the symmetrizer  $S$  given in definition 3. We consider  $z \in \mathcal{O} \cap \mathcal{U}$  and  $W_1 \in \mathbb{E}^s(z)$ . We then define the sequence:

$$W_{j+1} = \mathbb{M}(z) W_j, \quad j \geq 1. \quad (23)$$

Because  $W_1 \in \mathbb{E}^s(z)$ , we have  $(W_j) \in \ell^2$ . Following some calculations of [9, page 681], we first take the scalar product of (23) with  $S(z) W_{j+1}$ , take the real part of the equality and sum for  $j = 1$  to some integer  $J$ :

$$\text{Re} \sum_{j=1}^J W_{j+1}^* S(z) \mathbb{M}(z) W_j - \sum_{j=2}^{J+1} W_j^* S(z) W_j = 0. \quad (24)$$

Then we take the scalar product of (23) with  $S(z) \mathbb{M}(z) W_j$ , take the real part of the equality and sum for  $j = 1$  to  $J$ :

$$\sum_{j=1}^J W_j^* \mathbb{M}(z)^* S(z) \mathbb{M}(z) W_j - \text{Re} \sum_{j=1}^J W_{j+1}^* S(z) \mathbb{M}(z) W_j = 0. \quad (25)$$

The sum of (24) and (25) yields:

$$W_1^* S(z) W_1 - W_{J+1}^* S(z) W_{J+1} + \sum_{j=1}^J \underbrace{W_j^* (\mathbb{M}(z)^* S(z) \mathbb{M}(z) - S(z)) W_j}_{\geq 0} = 0.$$

Letting  $J$  tend to infinity, we obtain  $W_1^* S(z) W_1 \leq 0$  for all  $W_1 \in \mathbb{E}^s(z)$ . Using the properties of  $S$ , we obtain:

$$\forall z \in \mathcal{O} \cap \mathcal{U}, \quad \forall W_1 \in \mathbb{E}^s(z), \quad K |\underline{\pi}^u W_1| \leq |\underline{\pi}^s W_1|.$$

The end of the analysis follows [14]. Writing  $\underline{\pi}^s W_1 = W_1 - \underline{\pi}^u W_1$ , we get:

$$\forall z \in \mathcal{O} \cap \mathcal{U}, \quad \forall W_1 \in \mathbb{E}^s(z), \quad (K-1) |\underline{\pi}^u W_1| \leq |W_1|. \quad (26)$$

The estimate (26) shows that the mapping:

$$\begin{aligned} \Phi(z) : \mathbb{E}^s(z) &\longrightarrow \underline{\mathbb{E}}^s \\ W_1 &\longmapsto \underline{\pi}^s W_1, \end{aligned}$$

is injective, and is therefore an isomorphism because the dimensions of  $\mathbb{E}^s(z)$  and  $\underline{\mathbb{E}}^s$  are equal. We can then write the inverse mapping  $\Phi(z)^{-1}$  in the following way:

$$\begin{aligned} \Phi(z)^{-1} : \underline{\mathbb{E}}^s &\longrightarrow \mathbb{E}^s(z) \\ \underline{W}_1 &\longmapsto \underline{W}_1 + \varphi(z) \underline{W}_1, \end{aligned}$$

where  $\varphi(z)$  is a linear mapping from  $\underline{\mathbb{E}}^s$  to  $\underline{\mathbb{E}}^u$ . Using (26) we have:

$$\forall z \in \mathcal{O} \cap \mathcal{U}, \quad \forall \underline{W}_1 \in \underline{\mathbb{E}}^s, \quad |\varphi(z) \underline{W}_1| \leq \frac{1}{K-2} |\underline{W}_1|. \quad (27)$$

Combining the fact that  $\Phi(z)^{-1}$  is surjective and the estimate (27) shows that the space  $\mathbb{E}^s(z)$  tends to  $\underline{\mathbb{E}}^s$  as  $z \in \mathcal{U}$  tends to  $\underline{z}$ . We have thus extended  $\mathbb{E}^s$  to  $\overline{\mathcal{U}}$ . Following again [14] and performing some similar calculations as above, we can show that this extension of  $\mathbb{E}^s$  to  $\overline{\mathcal{U}}$  defines a continuous vector bundle over  $\overline{\mathcal{U}}$ . We refer to [14] for more details.

From now on, we further assume that for all  $z \in \overline{\mathcal{U}}$  we have  $\mathbb{E}^s(z) \cap \text{Ker } B(z) = \{0\}$ , which is the uniform Kreiss-Lopatinskii condition. We are going to show that the scheme (2) is strongly stable. We first consider the case of large frequencies  $z$ :

**Lemma 4** ([9]). *There exist two constants  $R_0 \geq 2$  and  $C_0 \geq 0$  that depend only on the scheme (2) such that for all  $z$  verifying  $|z| \geq R_0$ , for all  $(F_j) \in \ell^2$  and all  $g_{-r+1}, \dots, g_0 \in \mathbb{C}^N$ , the resolvent equation (5) has a unique solution  $(w_j) \in \ell^2$  and this solution satisfies:*

$$\sum_{j \geq -r+1} |w_j|^2 \leq C_0 \left( \sum_{j \geq 1} |F_j|^2 + \sum_{j=-r+1}^0 |g_j|^2 \right).$$

*Proof.* For  $z = \infty$ , the resolvent equation (5) formally reduces to:

$$\begin{cases} w_j = F_j, & j \geq 1, \\ w_j - B_{j,-1} w_1 = g_j, & j = -r+1, \dots, 0. \end{cases} \quad (28)$$

We let  $\mathcal{R}(F, g)$  denote the sequence  $(w_j)_{j \geq -r+1}$  solution to (28). It is clear that  $\mathcal{R}$  is a continuous linear operator on the Hilbert space  $\ell^2 \times \mathbb{C}^{N^r}$  with values in  $\ell^2$ . For  $z \in \mathcal{U}$ , the resolvent equation (5) may be recast as:

$$w = \mathcal{R} \left( F + \left( \sum_{\sigma=0}^s z^{-\sigma-1} Q_{\sigma} w_j \right)_{j \geq 1}, g + \left( \sum_{\sigma=0}^s z^{-\sigma-1} B_{j,\sigma} w_1 \right)_{j=-r+1, \dots, 0} \right),$$

which is a fixed point problem. This problem may be solved, for large enough  $|z|$ , by applying the Banach fixed point Theorem, which gives a unique solution  $w \in \ell^2$ . We omit the details that are almost straightforward. The estimate of the solution  $w \in \ell^2$  in terms of  $F$  and  $g$  is also straightforward.  $\square$

It remains to solve the resolvent equation when  $|z| \in ]1, R_0]$  and to obtain the corresponding estimate (6). We are first going to prove that for  $|z| \in ]1, R_0]$ , the resolvent equation satisfies an a priori estimate. More precisely, let  $(w_j) \in \ell^2$ , and let  $F \in \ell^2$ ,  $g_{-r+1}, \dots, g_0$  be defined such that (5) holds. We rewrite (5) under the equivalent form (9), as detailed in the introduction. Then we have:

**Lemma 5.** *There exists a constant  $c_0 > 0$  and there exists a  $\mathcal{C}^\infty$  function  $S$  on the closed annulus  $\{1 \leq |\zeta| \leq R_0\}$  with values in  $\mathcal{M}_{N(p+r)}(\mathbb{C})$  such that the following properties hold for all  $z \in \{1 \leq |\zeta| \leq R_0\}$ :*

- $S(z)$  is hermitian,
- $\mathbb{M}(z)^* S(z) \mathbb{M}(z) - S(z) \geq c_0 (|z| - 1)/|z| I$ ,
- for all  $W \in \mathbb{C}^{N(p+r)}$ ,  $W^* S(z) W \geq c_0 |W|^2 - |B(z) W|^2 / c_0$ .

The proof of Lemma 5 follows from the existence of a  $K$ -symmetrizer and from the uniform Kreiss-Lopatinskii condition. We first construct the symmetrizer  $S$  in the neighborhood of any point of the annulus  $\{1 \leq |\zeta| \leq R_0\}$  by choosing  $K$  sufficiently large. We refer to [15] for a similar analysis. The construction of a global smooth symmetrizer on the annulus requires a partition of unity as in the analysis of the continuous problem, see e.g. [2, 11]. Using the symmetrizer  $S$  of Lemma 5, we can perform some similar calculations to what we have done at the beginning of this section to obtain relations (24) and (25). Here the source term  $\widetilde{F}_j$  has to be taken into account, while it did not appear in (23). We obtain:

$$W_1^* S(z) W_1 + \sum_{j=1}^{+\infty} W_j^* (\mathbb{M}(z)^* S(z) \mathbb{M}(z) - S(z)) W_j = -\text{Re} \sum_{j=1}^{+\infty} (S(z) W_{j+1} + S(z) \mathbb{M}(z) W_j)^* \widetilde{F}_j.$$

Using some uniform bounds for  $S(z)$  and  $\mathbb{M}(z)$  on the annulus as well as the properties of  $S$  given in Lemma 5, we end up with:

$$\frac{|z| - 1}{|z|} \sum_{j \geq 1} |W_j|^2 + |W_1|^2 \leq C_1 \left\{ \frac{|z|}{|z| - 1} \sum_{j \geq 1} |\widetilde{F}_j|^2 + |g|^2 \right\},$$

for some appropriate numerical constant  $C_1$ . This estimate immediately yields the a priori estimate (6) for (5) when  $|z| \in ]1, R_0]$  by using the definition of  $(W_j), (\widetilde{F}_j), g$ .

Up to now, we have only proved an a priori estimate for the resolvent equation (5) when  $|z| \in ]1, R_0]$ . It remains to show that (5) may be solved in a unique way for arbitrary source terms. This step of the proof did not appear in [9]. We make use of the following general result:

**Lemma 6.** *Let  $E$  be a Banach space, and let  $\mathcal{T}$  denote a nonempty connected set. Let  $L$  be a continuous function defined on  $\mathcal{T}$  with values in the space  $\mathcal{L}(E)$  of continuous linear maps on  $E$ . Assume moreover that the two following conditions are satisfied:*

- *there exists a constant  $C_0 > 0$  such that for all  $t \in \mathcal{T}$  and for all  $x \in E$ , we have  $|x|_E \leq C_0 |L(t)x|_E$ ,*
- *there exists some  $t_0 \in \mathcal{T}$  such that  $L(t_0)$  is an isomorphism.*

*Then  $L(t)$  is an isomorphism for all  $t \in \mathcal{T}$ .*

The proof of Lemma 6 is given in appendix B. Lemma 6 shows that the resolvent equation can be uniquely solved for all  $z \in \mathcal{U}$ . Indeed, for all  $z \in \mathcal{U}$ , we define the mapping:

$$L(z) : \ell^2 \longrightarrow \ell^2$$

$$w \longmapsto L(z)w \quad \text{with } (L(z)w)_j := \begin{cases} w_j - \sum_{\sigma=0}^s z^{-\sigma-1} Q_\sigma w_j, & j \geq 1, \\ w_j - \sum_{\sigma=-1}^s z^{-\sigma-1} B_{j,\sigma} w_1, & j = -r+1, \dots, 0. \end{cases}$$

We can easily verify that  $L$  is a continuous map from  $\mathcal{U}$  to the set  $\mathcal{L}(\ell^2)$  and for all  $|z| \geq R_0$ ,  $L(z)$  is an isomorphism thanks to Lemma 4. We can then apply Lemma 6 on every annulus  $\{1+\varepsilon \leq |z| \leq 1/\varepsilon\}$ ,  $\varepsilon > 0$  small enough, and conclude that  $L(z)$  is an isomorphism for all  $z \in \mathcal{U}$ . This shows that the resolvent equation (5) can be uniquely solved for all  $z \in \mathcal{U}$  and all source terms  $F \in \ell^2$ ,  $g_{-r+1}, \dots, g_0 \in \mathbb{C}^N$ . The corresponding estimate of the unique solution  $w \in \ell^2$  follows from the analysis above and we have therefore proved that the scheme (2) is strongly stable. The proof of Theorem 2 is complete.

## 5 Proof of Theorem 3

Using the result of Lemma 1, we know that the “stable” subspace  $\mathbb{E}^s(z)$  of  $\mathbb{M}(z)$  has constant dimension  $Nr$  for all  $z \in \mathcal{U}$  and varies holomorphically with respect to  $z \in \mathcal{U}$ . Using Theorem 1 we also know that  $\mathbb{M}$  satisfies the discrete block structure condition. We are now going to build a  $K$ -symmetrizer in the neighborhood of any point  $\underline{z} \in \mathcal{U}$ .

We first consider a point  $\underline{z} \in \mathcal{U}$ . Using Theorem 1 we can reduce the matrix  $\mathbb{M}(\underline{z})$  to a block-diagonal form<sup>4</sup>:

$$\underline{T}^{-1} \mathbb{M}(\underline{z}) \underline{T} = \text{diag} (\underline{\mathbb{M}}^s, \underline{\mathbb{M}}^u).$$

The first block  $\underline{\mathbb{M}}^s$  satisfies  $(\underline{\mathbb{M}}^s)^* \underline{\mathbb{M}}^s \leq (1-\delta)I$  and the second block  $\underline{\mathbb{M}}^u$  satisfies  $(\underline{\mathbb{M}}^u)^* \underline{\mathbb{M}}^u \geq (1+\delta)I$  for some appropriate constant  $\delta > 0$ . It is then easy to construct a  $K$ -symmetrizer, the spaces  $\underline{\mathbb{E}}^s$ ,  $\underline{\mathbb{E}}^u$  in the decomposition of  $\mathbb{C}^{N(p+r)}$  being nothing but the “stable” and “unstable” subspace of  $\mathbb{M}(\underline{z})$  associated with eigenvalues in  $\mathbb{D}$  and  $\mathcal{U}$ . We let  $\underline{\pi}^s, \underline{\pi}^u$  denote the corresponding projectors. Then there exists a constant  $c_0 > 0$  such that for all  $W \in \mathbb{C}^{N(p+r)}$ , the following estimates hold:

$$c_0 |\underline{\pi}^s W| \leq |(\underline{T}^{-1} W)_1| \leq \frac{1}{c_0} |\underline{\pi}^s W|, \quad c_0 |\underline{\pi}^u W| \leq |(\underline{T}^{-1} W)_2| \leq \frac{1}{c_0} |\underline{\pi}^u W|,$$

where we use the notation  $U = (U_1, U_2)$  with  $U_1 \in \mathbb{C}^{Nr}$ ,  $U_2 \in \mathbb{C}^{Np}$  for any vector  $U \in \mathbb{C}^{N(p+r)}$ . The symmetrizer  $S$  can be chosen independent of  $z$  as follows:

$$S := (\underline{T}^{-1})^* \text{diag} \left( -\frac{c_0^2}{2} I, \frac{K^2 + 1/2}{c_0^2} I \right) \underline{T}^{-1}.$$

---

<sup>4</sup>Recall that for  $\underline{z} \in \mathcal{U}$ , blocks of the third and fourth type do not appear in the discrete block structure.

Then  $\mathbb{M}(\underline{z})^* S \mathbb{M}(\underline{z}) - S$  is positive definite, and we have:

$$W^* S W \geq \left(K^2 + \frac{1}{2}\right) |\underline{\pi}^u W|^2 - \frac{1}{2} |\underline{\pi}^s W|^2.$$

Choosing  $S$  independent of  $z$ , and  $z$  sufficiently close to  $\underline{z}$ , we have constructed a  $K$ -symmetrizer near  $\underline{z}$ .

We turn to the case  $\underline{z} \in \mathbb{S}^1$ . Using Theorem 1, we can first reduce  $\mathbb{M}$  to a block-diagonal form with a holomorphic change of basis on a neighborhood  $\mathcal{O}$  of  $\underline{z}$ :

$$T(z)^{-1} \mathbb{M}(z) T(z) = \text{diag} \\ (\mathbb{M}^s(z), \mathbb{M}^u(z), m_1^s(z), \dots, m_I^s(z), m_1^u(z), \dots, m_J^u(z), H_1(z), \dots, H_K(z), P_1(z), \dots, P_L(z)),$$

where in the terminology of definition 2  $\mathbb{M}^s$  is a block of the first type,  $\mathbb{M}^u$  is a block of the second type, the  $m_i^s$ 's (resp.  $m_j^u$ 's) are blocks of the third type with  $\underline{z} (m_i^s)'(\underline{z}) \overline{m_i^s(\underline{z})} < 0$  (resp.  $\underline{z} (m_j^u)'(\underline{z}) \overline{m_j^u(\underline{z})} > 0$ ). Eventually the blocks  $H_k$ 's and  $P_\ell$ 's are of the fourth type, the size of each block  $P_\ell$  is 2, and we have:

$$\det(H_k(z) - \kappa I) = \vartheta(\kappa, z) (z - \Lambda_k(\kappa)), \quad \Lambda_k(\underline{\kappa}_k) = \underline{z}, \quad \Lambda_k'(\underline{\kappa}_k) = 0, \\ \det(P_\ell(z) - \kappa I) = \vartheta(\kappa, z) (z - \lambda_\ell(\kappa)), \quad \lambda_\ell(\underline{\kappa}_\ell) = \underline{z}, \quad \lambda_\ell'(\underline{\kappa}_\ell) = 0, \quad \text{Re}(\underline{\kappa}_\ell^2 \underline{z} \lambda_\ell''(\underline{\kappa}_\ell)) > 0.$$

In the relations above, the numbers  $\underline{\kappa}_1, \dots, \underline{\kappa}_K, \underline{\kappa}_1, \dots, \underline{\kappa}_L$  all belong to  $\mathbb{S}^1$ . Moreover, we have  $\Lambda_k(\kappa) \in \mathbb{S}^1$  for all  $\kappa \in \mathbb{S}^1$  close enough to  $\underline{\kappa}_k$ . The generic notation  $\vartheta$  is again used to denote a holomorphic function of its arguments that does not vanish. The blocks  $H_k$ 's will be referred to as “hyperbolic blocks” while the blocks  $P_\ell$ 's will be referred to as “parabolic blocks”. This terminology will be clarified below.

To prove the existence of a  $K$ -symmetrizer for  $\mathbb{M}$  in the neighborhood of  $\underline{z}$ , we are first going to construct a  $K$ -symmetrizer for the block-diagonal matrix  $\tilde{\mathbb{M}} := T^{-1} \mathbb{M} T$ . The decomposition of  $\mathbb{C}^{N(p+r)}$  is defined as follows. For each block  $H_k$ , we let  $\mu_k$  denote the number of eigenvalues of  $H_k(z)$  in  $\mathbb{D}$  for  $z \in \mathcal{O} \cap \mathcal{U}$ . This number is independent of  $z$  thanks to Lemma 1. We also let  $\nu_k$  (resp.  $\nu_s, \nu_u$ ) denote the size of the block  $H_k$  (resp.  $\mathbb{M}^s, \mathbb{M}^u$ ). Then we define:

$$\tilde{\mathbb{E}}^s := \mathbb{C}^{\nu_s} \oplus \{0\} \oplus_{i=1}^I \mathbb{C}^1 \oplus_{j=1}^J \{0\} \oplus_{k=1}^K \mathbb{C}^{\mu_k} \times \{0\} \oplus_{\ell=1}^L \mathbb{C}^1 \times \{0\}, \\ \tilde{\mathbb{E}}^u := \{0\} \oplus \mathbb{C}^{\nu_u} \oplus_{i=1}^I \{0\} \oplus_{j=1}^J \mathbb{C}^1 \oplus_{k=1}^K \{0\} \times \mathbb{C}^{\nu_k - \mu_k} \oplus_{\ell=1}^L \{0\} \times \mathbb{C}^1,$$

where the decomposition of  $\tilde{\mathbb{E}}^s, \tilde{\mathbb{E}}^u$  follows the block-diagonal form of  $\tilde{\mathbb{M}}(z)$ , and where the notation  $\mathbb{C}^{\mu_k} \times \{0\}$  (resp.  $\{0\} \times \mathbb{C}^{\nu_k - \mu_k}$ ) denotes the subspace of  $\mathbb{C}^{\nu_k}$  spanned by the  $\mu_k$  first (resp.  $\nu_k - \mu_k$  last) vectors of the canonical basis. Observe that each block  $P_\ell(z)$  has exactly one eigenvalue in  $\mathbb{D}$  and one eigenvalue in  $\mathcal{U}$  for  $z \in \mathcal{O} \cap \mathcal{U}$ , so the dimension of  $\tilde{\mathbb{E}}^s$  (resp.  $\tilde{\mathbb{E}}^u$ ) equals  $Nr$  (resp.  $Np$ ). We let  $\tilde{\pi}^s, \tilde{\pi}^u$  denote the projectors associated with the decomposition  $\mathbb{C}^{N(p+r)} = \tilde{\mathbb{E}}^s \oplus \tilde{\mathbb{E}}^u$ .

We now fix a constant  $K \geq 1$ . The symmetrizer  $\tilde{S}(z)$  for the matrix  $\tilde{\mathbb{M}}(z)$  is chosen in block-diagonal form:

$$\tilde{S}(z) := \text{diag} (\mathbf{S}^s, \mathbf{S}^u, r_1^s, \dots, r_I^s, r_1^u, \dots, r_J^u, R_1(z), \dots, R_K(z), S_1(z), \dots, S_L(z)),$$

and we detail now the construction of each block in the symmetrizer.

• Construction of the constant matrices  $\mathbf{S}^s$  and  $\mathbf{S}^u$ . These matrices are defined as in the case  $\underline{z} \in \mathcal{U}$  by  $\mathbf{S}^s := -I/2$  and  $\mathbf{S}^u := (K^2 + 1/2)I$ . For  $z \in \overline{\mathcal{U}}$  sufficiently close to  $\underline{z}$ , we have:

$$\mathbb{M}^s(z)^* \mathbf{S}^s \mathbb{M}^s(z) - \mathbf{S}^s \geq c \frac{|z| - 1}{|z|} I, \quad \mathbb{M}^u(z)^* \mathbf{S}^u \mathbb{M}^u(z) - \mathbf{S}^u \geq c \frac{|z| - 1}{|z|} I,$$

for some appropriate constant  $c > 0$ .

• Construction of the numbers  $r_1^s, \dots, r_I^s, r_1^u, \dots, r_J^u$ . Let us begin with the following:

**Lemma 7.** *We have  $m_1^s(z), \dots, m_I^s(z) \in \mathbb{D}$  and  $m_1^u(z), \dots, m_J^u(z) \in \mathcal{U}$  for all  $z \in \mathcal{O} \cap \mathcal{U}$ . Moreover up to shrinking the neighborhood  $\mathcal{O}$  of  $\underline{z}$ , there exists a constant  $c > 0$  such that the following inequalities hold for all  $z \in \mathcal{O} \cap \overline{\mathcal{U}}$ :*

$$\begin{aligned} \forall i = 1, \dots, I, \quad & |m_i^s(z)|^2 - 1 \leq -c \frac{|z| - 1}{|z|}, \\ \forall j = 1, \dots, J, \quad & |m_j^u(z)|^2 - 1 \geq c \frac{|z| - 1}{|z|}. \end{aligned}$$

*Proof.* There is no loss of generality in assuming that  $\mathcal{O}$  is connected. Then for  $z \in \mathcal{O} \cap \mathcal{U}$ ,  $m_i^s(z)$  and  $m_j^u(z)$  are eigenvalues of  $\mathbb{M}(z)$  so they cannot belong to  $\mathbb{S}^1$ . Performing a Taylor expansion of  $m_i^s((1 + \varepsilon)\underline{z})$  and  $m_j^u((1 + \varepsilon)\underline{z})$  for  $\varepsilon > 0$  small, we see that  $m_i^s((1 + \varepsilon)\underline{z}) \in \mathbb{D}$  and  $m_j^u((1 + \varepsilon)\underline{z}) \in \mathcal{U}$  for  $\varepsilon > 0$  small enough. Since  $\mathcal{O} \cap \mathcal{U}$  is connected, we have  $m_i^s(z) \in \mathbb{D}$  and  $m_j^u(z) \in \mathcal{U}$  for all  $z \in \mathcal{O} \cap \mathcal{U}$ .

For simplicity, let us now deal with  $m_1^s$ . For  $\tau$  in a small neighborhood of 0, we define:

$$h(\tau) := \ln \frac{m_1^s(\underline{z} e^\tau)}{m_1^s(\underline{z})},$$

where  $\ln$  denotes the standard logarithm defined on  $\mathbb{C} \setminus \mathbb{R}^-$ . We have  $h'(0) = \underline{z} (m_1^s)'(\underline{z}) \overline{m_1^s(\underline{z})} < 0$ , and we also know that  $h(\tau)$  has negative real part when  $\tau$  has positive real part. In particular,  $h(\tau)$  has nonpositive real part when  $\tau$  is purely imaginary. Then a direct Taylor expansion yields the estimate<sup>5</sup>:

$$\operatorname{Re} h(\tau) \leq \frac{h'(0)}{4} \operatorname{Re} \tau,$$

for  $\operatorname{Re} \tau \geq 0$  and  $\tau$  close to 0. The estimate for  $|m_1^s(z)|^2$  easily follows. The case of the  $m_j^u$ 's is similar.  $\square$

For all  $i = 1, \dots, I$  we define  $r_i^s := -1/2$  and for all  $j = 1, \dots, J$  we define  $r_j^u := K^2 + 1/2$ . Using Lemma 7, we have:

$$r_i^s (|m_i^s(z)|^2 - 1) \geq c \frac{|z| - 1}{|z|}, \quad r_j^u (|m_j^u(z)|^2 - 1) \geq c \frac{|z| - 1}{|z|},$$

for some appropriate constant  $c > 0$  and for all  $z \in \mathcal{O} \cap \overline{\mathcal{U}}$ .

• Construction of the symmetrizers  $S_1(z), \dots, S_L(z)$ . This is the main difficulty in the proof of Theorem 3 where new arguments are needed. For simplicity, we are going to construct the symmetrizer  $S_1(z)$  associated with the block  $P_1(z)$ . Recall that we have:

$$\det(P_1(z) - \kappa I) = \vartheta(\kappa, z) (z - \lambda_1(\kappa)), \quad \lambda_1(\kappa_1) = \underline{z}, \quad \lambda_1'(\kappa_1) = 0, \quad \operatorname{Re}(\kappa_1^2 \underline{z} \lambda_1''(\kappa_1)) > 0.$$

<sup>5</sup>Here we use the crucial fact that  $\operatorname{Re} h(iy) \leq 0$  for all real  $y$  close to 0. The only inequality  $h'(0) < 0$  is not sufficient to yield the estimate. This part of the analysis was not so clear in [9, page 678].

According to Theorem 1, we even know that the lower left coefficient  $\omega_1$  of  $P_1'(z)$  satisfies  $\omega_1 \neq 0$  and  $\operatorname{Re}(\overline{\kappa_1} \omega_1 \underline{z}) \geq 0$ . Indeed these two conditions can be seen to be equivalent to the property stated in definition 2 for a  $2 \times 2$  block. We are first going to prove that the real part of  $\overline{\kappa_1} \omega_1 \underline{z}$  is positive. To prove this property, let us write:

$$P_1(z) = \kappa_1 \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} p_1(z) & p_3(z) \\ p_2(z) & p_4(z) \end{pmatrix}, \quad p_2'(z) = \omega_1.$$

Using the fact that  $\kappa$  is an eigenvalue of  $P_1(\lambda_1(\kappa))$  for all  $\kappa$  close to  $\kappa_1$ , we obtain:

$$(\kappa - \kappa_1)^2 = (\kappa - \kappa_1) (p_1(z) + p_4(z)) - p_1(z) p_4(z) + p_2(z) (\kappa_1 + p_3(z))|_{z=\lambda_1(\kappa)}.$$

Differentiating twice and evaluating at  $\kappa = \kappa_1$ , we obtain  $\omega_1 = 2/(\kappa_1 \lambda_1''(\kappa_1))$ . The inequality  $\operatorname{Re}(\overline{\kappa_1} \omega_1 \underline{z}) > 0$  immediately follows from the assumption on  $\lambda_1$ .

To construct a symmetrizer for  $P_1$ , it is easier to work in “flat” coordinates. In the original coordinates,  $z$  belongs to the exterior of a disc so the curvature of the disc makes the calculations heavier. We shall reduce below to coordinates in a half-space. Let us denote  $\xi_1$  the argument of  $\kappa_1$ , that is  $\kappa_1 = \exp(i \xi_1)$ . Then we can define a matrix that depends holomorphically on  $z$  in a neighborhood of  $\underline{z}$  by the following formula:

$$\mathbf{P}_1(z) := i \xi_1 I + \sum_{n=1}^{+\infty} \frac{(-1)^{n-1}}{n} (\overline{\kappa_1} P_1(z) - I)^n.$$

This matrix satisfies  $P_1(z) = \exp \mathbf{P}_1(z)$  for all  $z$  close enough to  $\underline{z}$ . We compute:

$$\mathbf{P}_1(\underline{z}) = \begin{pmatrix} i \xi_1 & 1 \\ 0 & i \xi_1 \end{pmatrix} = i \xi_1 I + N. \quad (29)$$

The first derivative  $\mathbf{P}_1'(\underline{z})$  is related to  $P_1'(\underline{z})$  through the differential of the exponential function at  $\mathbf{P}_1(\underline{z})$ . More precisely, we recall the following formula that is fully justified in [17, page 78]:

$$d \exp|_A B := \frac{d}{dz} \exp(A + z B)|_{z=0} = \exp(A) \sum_{p=0}^{+\infty} \frac{(-1)^p}{(p+1)!} (\operatorname{ad} A)^p B, \quad (\operatorname{ad} A) B := A B - B A. \quad (30)$$

We differentiate the relation  $P_1(z) = \exp \mathbf{P}_1(z)$ , evaluate at  $z = \underline{z}$  and use (29), (30) to obtain:

$$\overline{\kappa_1} P_1'(\underline{z}) = \mathbf{P}_1'(\underline{z}) + \frac{1}{2} (N \mathbf{P}_1'(\underline{z}) + \mathbf{P}_1'(\underline{z}) N) + \frac{1}{6} N \mathbf{P}_1'(\underline{z}) N. \quad (31)$$

The nilpotent matrix  $N$  is defined in (29). The relation (31) shows that the lower left element of  $\mathbf{P}_1'(\underline{z})$  equals  $\overline{\kappa_1} \omega_1$ . Eventually, we define the matrix:

$$\mathbb{P}_1(\tau) := Q_0^{-1} \mathbf{P}_1(\underline{z} e^\tau) Q_0, \quad Q_0 := \operatorname{diag}(-i, 1). \quad (32)$$

It depends holomorphically on  $\tau$  in a neighborhood of 0 and satisfies  $\mathbb{P}_1(0) = i(\xi_1 I + N)$ . Moreover, the lower left coefficient of  $\mathbb{P}_1'(0)$ , that is from now on denoted  $\alpha_1$ , has negative imaginary part.

If we want to see the analogy and the differences with the analysis of the continuous problem, for which we refer to [11, 2], we need to introduce a final change of basis that is due to Ralston (see [19] for the relevance of this change of basis):

$$Q(\tau) := (-i(\mathbb{P}_1(\tau) - i \xi_1 I) e_2 \quad e_2), \quad e_2 := \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The matrix  $Q(\tau)$  depends holomorphically on  $\tau$ , it attains the value  $I$  for  $\tau = 0$  and is therefore invertible for  $\tau$  close to 0. Moreover, the matrix  $Q^{-1} \mathbb{P}_1 Q$  reads:

$$\check{\mathbb{P}}_1(\tau) := Q(\tau)^{-1} \mathbb{P}_1(\tau) Q(\tau) = i(\xi_1 I + N) + \begin{pmatrix} b_1(\tau) & 0 \\ b_2(\tau) & 0 \end{pmatrix}, \quad (33)$$

where the functions  $b_1, b_2$  are holomorphic and vanish for  $\tau = 0$ . Moreover, we compute  $b'_2(0) = \alpha_1$ . Let us recall that  $\alpha_1$  denotes the lower left coefficient of  $\mathbb{P}'_1(0)$  and has negative imaginary part.

After all these preliminary transformations, the construction of the symmetrizer  $S_1$  relies on the following:

**Lemma 8.** *There exist a neighborhood of 0, a  $\mathcal{C}^\infty$  mapping  $\check{S}$  defined on this neighborhood with values in  $\mathcal{M}_2(\mathbb{C})$ , and there exists a constant  $c > 0$  such that for all  $\tau$  close to 0 the following properties hold:*

- $\check{S}(\tau)$  is hermitian,
- $\operatorname{Re}(\check{S}(\tau) \check{\mathbb{P}}_1(\tau)) \geq c(\operatorname{Re} \tau + (\operatorname{Im} \tau)^2) I$  if  $\operatorname{Re} \tau \geq 0$ ,
- for all  $W \in \mathbb{C}^2$ ,  $W^* \check{S}(0) W \geq (K^2 + 1/2) |W_2|^2 - |W_1|^2/2$ .

*Proof.* The proof follows the ideas in [11] but we can not adopt the same construction here. Some new ingredients are needed<sup>6</sup>. The additional term  $(\operatorname{Im} \tau)^2$  in the estimate explains the terminology “parabolic block” introduced above for  $P_1$ . This new term appears because of the “dissipation” assumption made on  $\lambda_1$ .

In all the proof of Lemma 8, we use the notation  $\tau = \gamma + i\delta$ . The symmetrizer  $\check{S}$  is sought, as in [11], under the form:

$$\check{S}(\tau) = \check{S}_0(\delta) + \gamma \check{S}_1,$$

where  $\check{S}_0$  is a  $\mathcal{C}^\infty$  function of the real variable  $\delta$ , and  $\check{S}_1$  is a constant hermitian matrix<sup>7</sup>. The matrix  $\check{S}_0(\delta)$  is chosen under the form:

$$\check{S}_0(\delta) := \begin{pmatrix} 0 & \overline{\alpha_1} + c_0 \delta \\ \alpha_1 + c_0 \delta & a_0 \end{pmatrix},$$

where  $a_0, c_0$  are real constants. Decomposing  $b_2(i\delta) = i\alpha_1\delta + \delta^2 b_3(\delta)$  for some analytic function  $b_3$ , (33) and our choice of  $\check{S}_0$  yield:

$$\begin{aligned} \operatorname{Re}(\check{S}_0(\delta) \check{\mathbb{P}}_1(i\delta)) &= \begin{pmatrix} c_0 \delta^2 (-\operatorname{Im} \alpha_1 + \delta b_3(\delta)) + \delta^2 \operatorname{Re}(\overline{\alpha_1} b_3(\delta)) & \star \\ ((\alpha_1 + c_0 \delta) b_1(i\delta) + a_0 b_2(i\delta))/2 & -\operatorname{Im} \alpha_1 \end{pmatrix} \\ &= \begin{pmatrix} \delta^2 (-c_0 \operatorname{Im} \alpha_1 + \operatorname{Re}(\overline{\alpha_1} b_3(0))) & \star \\ i\alpha_1 \delta (a_0 + b'_1(0))/2 & -\operatorname{Im} \alpha_1 \end{pmatrix} + \begin{pmatrix} O(\delta^3) & \star \\ O(\delta^2) & 0 \end{pmatrix}, \end{aligned}$$

where the  $\star$  coefficients are such that the matrices above are hermitian. We first fix the constant  $a_0$  large enough such that the following estimate holds:

$$\forall W \in \mathbb{C}^2, \quad W^* \check{S}_0(0) W \geq (K^2 + 1/2) |W_2|^2 - |W_1|^2/2.$$

<sup>6</sup>The problem treated by Kreiss [11] in the continuous case corresponds to  $\alpha_1 \in \mathbb{R} \setminus \{0\}$  while here, the “dissipation” assumption on  $\lambda_1$  yields  $\operatorname{Im} \alpha_1 < 0$ .

<sup>7</sup>In [11],  $\check{S}_0(\delta)$  can be chosen with real coefficients and such that the real part of  $\check{S}_0(\delta) \check{\mathbb{P}}_1(i\delta)$  is identically zero. In our case, it is not possible to choose a matrix  $\check{S}_0(\delta)$  with real coefficients so that the real part of  $\check{S}_0(\delta) \check{\mathbb{P}}_1(i\delta)$  is nonnegative.

Once  $a_0$  is fixed, we can choose  $c_0$  large enough such that for all  $\delta$  sufficiently small, we have:

$$\operatorname{Re} (\check{S}_0(\delta) \check{P}_1(i\delta)) \geq \delta^2 I.$$

Defining the matrix  $\check{S}_1$  as in [11] by:

$$\check{S}_1 := \begin{pmatrix} 0 & ig \\ -ig & 0 \end{pmatrix},$$

we compute:

$$\begin{aligned} \operatorname{Re} (\check{S}(\tau) \check{P}_1(\tau)) &= \operatorname{Re} (\check{S}_0(\delta) \check{P}_1(i\delta)) + \gamma \operatorname{Re} (\check{S}_0(0) \check{P}'_1(0) + \check{S}_1 \check{P}_1(0)) + \gamma o(1), \\ \operatorname{Re} (\check{S}_0(0) \check{P}'_1(0) + \check{S}_1 \check{P}_1(0)) &= \begin{pmatrix} |\alpha_1|^2 & \star \\ \alpha_1 (a_0 + b'_1(0))/2 & g \end{pmatrix}. \end{aligned}$$

Choosing  $g$  large enough, we obtain all the properties stated in Lemma 8 for the symmetrizer  $\check{S}(\tau)$ .  $\square$

Using the symmetrizer  $\check{S}$  of Lemma 8, we define  $S_1(z) := (Q(\tau)^{-1}Q_0^{-1})^* \check{S}(\tau) Q(\tau)^{-1}Q_0^{-1}$  where  $\tau = \ln(z/\underline{z})$ . The matrix  $S_1(z)$  is hermitian and  $S_1$  is a  $\mathcal{C}^\infty$  function of  $z$ . Using  $Q(0) = I$  and the explicit expression of  $Q_0$ , see (32), we also obtain:

$$\forall W \in \mathbb{C}^2, \quad W^* S_1(\underline{z}) W \geq (K^2 + 1/2) |W_2|^2 - |W_1|^2/2.$$

It remains to check that  $S_1(z)$  symmetrizes  $P_1(z)$ . This is done by following the calculations of [9, page 685] so we omit the details. With some appropriate constant  $c > 0$ , we obtain:

$$P_1(z)^* S_1(z) P_1(z) - S_1(z) \geq c \frac{|z| - 1}{|z|} I,$$

for all  $z \in \mathcal{U}$  close enough to  $\underline{z}$ .

• Construction of  $R_1(z), \dots, R_K(z)$ . Following the analysis of the preceding case, we can first write each hyperbolic block  $H_k(z)$  under the form  $H_k(z) = \exp \mathbf{H}_k(z)$ . Then up to a holomorphic change of basis  $Q$ , we can reduce  $\mathbf{H}_k$  to the following form (see [19]):

$$Q(\tau)^{-1} \mathbf{H}_k(\underline{z} e^\tau) Q(\tau) = \begin{pmatrix} i\xi_{\underline{z}_k} & i & 0 & 0 \\ 0 & \ddots & \ddots & 0 \\ \vdots & & \ddots & i \\ 0 & \dots & 0 & i\xi_{\underline{z}_k} \end{pmatrix} + \begin{pmatrix} b_1(\tau) & 0 & \dots & 0 \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ b_{\nu_k}(\tau) & 0 & \dots & 0 \end{pmatrix}.$$

This relation holds for all  $\tau$  in a sufficiently small neighborhood of 0. Moreover, following [13], we can show that  $b'_{\nu_k}(0)$  is a nonzero real number and that the  $b_j$ 's are purely imaginary valued when  $\tau$  is purely imaginary. The change of basis  $Q$  can be chosen such that  $Q(0)$  is upper triangular. Then the analysis of [11], see also [2], shows that there exists a  $K$ -symmetrizer  $R_k(z)$  for  $\mathbf{H}_k(z)$ . In particular,  $R_k$  satisfies:

$$W^* R_k(\underline{z}) W \geq (K^2 + 1/2) |W_2|^2 - 1/2 |W_1|^2,$$

where  $W = (W_1, W_2)$ ,  $W_1 \in \mathbb{C}^{\mu_k}$ ,  $W_2 \in \mathbb{C}^{\nu_k - \mu_k}$ . The calculations of [9, page 685] show that  $R_k$  is also a  $K$ -symmetrizer for the hyperbolic block  $H_k = \exp \mathbf{H}_k$ .

• End of the analysis. The definition of our symmetrizer  $\tilde{S}(z)$  shows that  $\tilde{S}$  is a  $\mathcal{C}^\infty$  function of  $z$  and it symmetrizes  $\tilde{\mathbb{M}} = T^{-1} M T$  in the following sense:

$$\tilde{\mathbb{M}}(z)^* \tilde{S}(z) \tilde{\mathbb{M}}(z) - \tilde{S}(z) \geq c \frac{|z| - 1}{|z|} I,$$

for  $z \in \overline{\mathcal{W}}$  sufficiently close to  $\underline{z}$ . Moreover, the matrix  $\tilde{S}(\underline{z})$  satisfies:

$$W^* \tilde{S}(\underline{z}) W \geq (K^2 + 1/2) |\tilde{\pi}^u W|^2 - 1/2 |\tilde{\pi}^s W|^2.$$

We now obtain the existence of a  $K$ -symmetrizer for  $\mathbb{M}$  by setting  $\underline{\mathbb{E}}^{s,u} := T(\underline{z}) \tilde{\underline{\mathbb{E}}}^{s,u}$ ,  $S(z) := (T(z)^{-1})^* \tilde{S}(z) T(z)^{-1}$  and so on. The proof of Theorem 3 is complete.

In appendix C we extend our analysis of parabolic blocks to the case of an eigenvalue  $\lambda_j$  that satisfies  $\lambda_j''(\underline{\kappa}) \neq 0$ ,  $\operatorname{Re}(\underline{\kappa}^2 \overline{\lambda_j(\underline{\kappa})} \lambda_j''(\underline{\kappa})) = 0$  but that satisfies a dissipation estimate of the form:

$$|\lambda_j(\underline{\kappa} e^{i\xi})| \leq 1 - c \xi^4,$$

for  $\xi \in \mathbb{R}$  close to 0. We show how to modify the symmetrizer construction above to take into account this weaker assumption. This extension shows that our construction is flexible enough in order to be adapted to any dissipation type assumption for the eigenvalue  $\lambda_j$ . The only case that we leave open here is when  $\lambda_j'(\underline{\kappa}) = \lambda_j''(\underline{\kappa}) = 0$  and when condition *ii*) in Theorem 2 is not satisfied (this situation leads to a block of size 3 or more). However we have no example of such a situation and we also strongly believe that the symmetrizer construction can be performed in this case under some additional dissipation assumption on  $\lambda_j$ , up to some more or less involved calculations.

## 6 Some old and new examples

In this section, we give some examples of numerical schemes for which our analysis applies. We do not focus on the numerical treatment of the boundary conditions but rather on the possible discretizations of the hyperbolic operator. For all the schemes below, the matrices  $A_{l,\sigma}$  in (3) are polynomials of the matrix  $\lambda A$ . All these matrices are therefore diagonalizable in a fixed basis where  $A$  is diagonal. Without loss of generality, we thus restrict in this section to the case of a scalar equation:

$$\partial_t u + a \partial_x u = f.$$

For simplicity, we assume  $a > 0$  but the case  $a < 0$  produces similar results. We recall that  $\mathcal{A}(\kappa)$  denotes the symbol defined by (4). For scalar equations and one-step schemes ( $s = 0$ ), this symbol is a complex number so the uniform power-boundedness and geometric regularity of eigenvalues reduce to the inequality  $|\mathcal{A}(\kappa)| \leq 1$  for all  $\kappa \in \mathbb{S}^1$ .

Let us begin with some classical first and second order schemes:

**The upwind scheme** The scheme reads:

$$u_j^{n+1} = \lambda a u_{j-1}^n + (1 - \lambda a) u_j^n,$$

and we compute:

$$\mathcal{A}(\kappa) = \lambda a \kappa^{-1} + (1 - \lambda a).$$

The scheme is  $\ell^2$ -stable (and geometrically regular) if and only if  $\lambda a \leq 1$ . Assumption 1 is also satisfied if  $\lambda a \leq 1$ . If  $\lambda a = 1$  we have  $|\mathcal{A}(\kappa)| = 1$  for all  $\kappa \in \mathbb{S}^1$  and  $\mathcal{A}'(\kappa) = -\kappa^{-2} \neq 0$ . If  $\lambda a < 1$  we have  $|\mathcal{A}(\kappa)| = 1$  if and only if  $\kappa = 1$ , and  $\mathcal{A}'(1) = -\lambda a \neq 0$ . The upwind scheme enters the framework of Theorem 3 if  $\lambda a \leq 1$ .

**The Lax-Friedrichs scheme** The scheme reads:

$$u_j^{n+1} = \frac{u_{j-1}^n + u_{j+1}^n}{2} - \frac{\lambda a}{2} (u_{j+1}^n - u_{j-1}^n),$$

and we compute:

$$\mathcal{A}(\kappa) = \frac{\kappa^{-1} + \kappa}{2} - \frac{\lambda a}{2} (\kappa - \kappa^{-1}).$$

The scheme is  $\ell^2$ -stable (and geometrically regular) if and only if  $\lambda a \leq 1$ . When  $\lambda a = 1$  the scheme reduces to the upwind scheme analyzed above so we further assume  $\lambda a < 1$ . In that case, assumption 1 is satisfied and we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if  $\kappa = \pm 1$ . Moreover  $\mathcal{A}'(\pm 1) = -\lambda a \neq 0$ . If  $\lambda a \leq 1$ , the Lax-Friedrichs scheme enters the framework of Theorem 3.

**The Lax-Wendroff scheme** The scheme reads:

$$u_j^{n+1} = u_j^n - \frac{\lambda a}{2} (u_{j+1}^n - u_{j-1}^n) + \frac{\lambda^2 a^2}{2} (u_{j+1}^n + u_{j-1}^n - 2u_j^n),$$

and we compute:

$$\mathcal{A}(\kappa) = 1 - \frac{\lambda a}{2} (\kappa - \kappa^{-1}) + \frac{\lambda^2 a^2}{2} (\kappa + \kappa^{-1} - 2).$$

The scheme is  $\ell^2$ -stable (and geometrically regular) if and only if  $\lambda a \leq 1$ . When  $\lambda a = 1$  the scheme reduces to the upwind scheme so we further assume  $\lambda a < 1$ . Assumption 1 is satisfied if  $\lambda a < 1$ . In that case, we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if  $\kappa = 1$ , and  $\mathcal{A}'(1) = -\lambda a \neq 0$ . If  $\lambda a \leq 1$ , the Lax-Wendroff scheme enters the framework of Theorem 3.

**The leap-frog scheme** The scheme reads:

$$u_j^{n+1} = u_j^{n-1} - \lambda a (u_{j+1}^n - u_{j-1}^n),$$

and we compute:

$$\mathcal{A}(\kappa) = \begin{pmatrix} -\lambda a (\kappa - \kappa^{-1}) & 1 \\ 1 & 0 \end{pmatrix}.$$

The scheme is  $\ell^2$ -stable and the eigenvalues of  $\mathcal{A}(\kappa)$  are geometrically regular if and only if  $\lambda a < 1$ . In that case, assumption 1 is satisfied. The eigenvalues of  $\mathcal{A}(e^{i\xi})$  are:

$$z_1(\xi) = -i \lambda a \sin \xi + \sqrt{1 - \lambda^2 a^2 \sin^2 \xi}, \quad z_2(\xi) = -i \lambda a \sin \xi - \sqrt{1 - \lambda^2 a^2 \sin^2 \xi}.$$

We have  $z_1(\xi), z_2(\xi) \in \mathbb{S}^1$  for all  $\xi \in \mathbb{R}$ . Since  $\lambda a < 1$ , we can also construct eigenvectors  $E_1(\xi)$  and  $E_2(\xi)$  associated with the eigenvalues  $z_1(\xi), z_2(\xi)$ . These eigenvalues and eigenvectors extend to a complex neighborhood of any point  $e^{i\xi}$  of  $\mathbb{S}^1$  so the eigenvalues of  $\mathcal{A}(\kappa)$  are geometrically regular. If  $\lambda a < 1$ , the leap-frog scheme enters the framework of Theorem 3.

We now turn to a more involved class of schemes:

**The Runge-Kutta schemes** We follow the description of Runge-Kutta schemes in [8, chapter 6]. Introducing the notation:

$$QU_j := \frac{2}{3} (U_{j+1} - U_{j-1}) - \frac{1}{12} (U_{j+2} - U_{j-2}),$$

which is a fourth-order approximation of the space derivative  $\partial_x U$ , the Runge-Kutta scheme of order 3 reads:

$$u_j^{n+1} = \sum_{\ell=0}^3 \frac{(-\lambda a Q)^\ell}{\ell!} u_j^n. \quad (34)$$

We compute:

$$\mathcal{A}(\kappa) = \sum_{\ell=0}^3 \frac{(-\lambda a \widehat{Q}(\kappa))^\ell}{\ell!}, \quad \widehat{Q}(\kappa) = \frac{2}{3}(\kappa - \kappa^{-1}) - \frac{1}{12}(\kappa^2 - \kappa^{-2}).$$

Assumption 1 is satisfied as long as  $a \neq 0$ . We thus check the  $\ell^2$ -stability of the scheme and compute:

$$|\mathcal{A}(e^{i\xi})|^2 = 1 - \frac{\lambda^4 a^4}{972} h(\xi)^4 \left(1 - \frac{\lambda^2 a^2}{27} h(\xi)^2\right), \quad h(\xi) := (4 - \cos \xi) \sin \xi.$$

The maximum of  $|h|$  on  $\mathbb{R}$  can be explicitly computed and equals  $|h(\xi_0)|$  where  $\xi_0$  satisfies  $\cos \xi_0 = 1 - \sqrt{6}/2$ . For later use, we let  $\beta$  denote the maximum<sup>8</sup> of  $|h|$  on  $\mathbb{R}$ . Then the scheme (34) is  $\ell^2$ -stable (and geometrically regular) if and only if  $\lambda a \leq 3\sqrt{3}/\beta$ . We now analyze the behavior of  $\mathcal{A}(\kappa)$  when it touches the unit circle  $\mathbb{S}^1$ .

If  $\lambda a < 3\sqrt{3}/\beta$ , we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if  $\kappa = \pm 1$ . In that case, we have  $\mathcal{A}'(1) = -\lambda a \neq 0$  and  $\mathcal{A}'(-1) = -(5/3)\lambda a \neq 0$ . If  $\lambda a = 3\sqrt{3}/\beta$ , we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if  $\kappa = \pm 1$  or  $\kappa = e^{\pm i\xi_0}$  with  $\xi_0$  defined above. We still have  $\mathcal{A}'(1) = -\lambda a \neq 0$  and  $\mathcal{A}'(-1) = -(5/3)\lambda a \neq 0$  but now we also have  $\mathcal{A}'(e^{\pm i\xi_0}) = 0$ . However, we can also compute:

$$\operatorname{Re} \left( e^{\pm 2i\xi_0} \overline{\mathcal{A}(e^{\pm i\xi_0})} \mathcal{A}''(e^{\pm i\xi_0}) \right) = \frac{27}{4\beta^2} \left( 3 - \frac{\sqrt{6}}{3} \right) > 0.$$

If  $\lambda a \leq 3\sqrt{3}/\beta$ , the Runge-Kutta scheme (34) enters the framework of Theorem 3.

The Runge-Kutta scheme of order 4 reads:

$$u_j^{n+1} = \sum_{\ell=0}^4 \frac{(-\lambda a Q)^\ell}{\ell!} u_j^n, \quad (35)$$

and we compute:

$$\mathcal{A}(\kappa) = \sum_{\ell=0}^4 \frac{(-\lambda a \widehat{Q}(\kappa))^\ell}{\ell!}.$$

Assumption 1 is again satisfied as long as  $a \neq 0$ . We thus check the  $\ell^2$ -stability of the scheme and compute:

$$|\mathcal{A}(e^{i\xi})|^2 = 1 - \frac{\lambda^6 a^6}{5832} h(\xi)^6 \left(1 - \frac{\lambda^2 a^2}{72} h(\xi)^2\right),$$

where the function  $h$  is defined as above. Then the scheme (35) is  $\ell^2$ -stable (and geometrically regular) if and only if  $\lambda a \leq 6\sqrt{2}/\beta$ . We now analyze the behavior of  $\mathcal{A}(\kappa)$  when it touches the unit circle.

If  $\lambda a < 6\sqrt{2}/\beta$ , we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if  $\kappa = \pm 1$ . In that case, we have  $\mathcal{A}'(1) = -\lambda a \neq 0$  and  $\mathcal{A}'(-1) = -(5/3)\lambda a \neq 0$ . If  $\lambda a = 6\sqrt{2}/\beta$ , we have  $\mathcal{A}(\kappa) \in \mathbb{S}^1$  if and only if

---

<sup>8</sup>The exact value of  $\beta$  is  $(3 + \sqrt{6}/2)\sqrt{\sqrt{6} - 3/2}$ .

$\kappa = \pm 1$  or  $\kappa = e^{\pm i\xi_0}$  with  $\xi_0$  defined above. We still have  $\mathcal{A}'(1) = -\lambda a \neq 0$  and  $\mathcal{A}'(-1) = -(5/3)\lambda a \neq 0$  but now we also have  $\mathcal{A}'(e^{\pm i\xi_0}) = 0$ . However, we can also compute:

$$\operatorname{Re} \left( e^{\pm 2i\xi_0} \overline{\mathcal{A}(e^{\pm i\xi_0})} \mathcal{A}''(e^{\pm i\xi_0}) \right) = \frac{576}{9\beta^2} \left( 3 - \frac{\sqrt{6}}{3} \right) > 0.$$

If  $\lambda a \leq 6\sqrt{2}/\beta$ , the Runge-Kutta scheme (35) enters the framework of Theorem 3. We have thus obtained two new situations where our analysis applies and that could not be analyzed with the theory in [9]. To illustrate the computations above, we show in figure 1 the curve  $\{\mathcal{A}(\kappa), \kappa \in \mathbb{S}^1\}$ . It touches the unit circle at a regular point and at two cusps that correspond to  $\kappa = e^{\pm 2i\xi_0}$ . For  $\xi$  close to  $\xi_0$ , we have an estimate of the form:

$$|\mathcal{A}(e^{i\xi})| \leq 1 - c(\xi - \xi_0)^2.$$

Figure 1: The curve  $\{\mathcal{A}(\kappa), \kappa \in \mathbb{S}^1\}$  (black dots), and the unit circle (red).

## A An elementary proof of Lemma 2

We assume that the matrix  $\mathcal{A}(\kappa)$  defined by (4) is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ , and that assumption 1 is satisfied. Applying the Kreiss matrix Theorem<sup>9</sup>, there exists a constant

<sup>9</sup>Here we only use the easy part of the Kreiss matrix Theorem so our proof is really elementary !

$C > 0$  such that:

$$\forall \kappa \in \mathbb{S}^1, \quad \forall z \in \mathcal{U}, \quad \|(\mathcal{A}(\kappa) - zI)^{-1}\| \leq \frac{C}{|z| - 1}.$$

Using the expression (4) of  $\mathcal{A}(\kappa)$ , we can compute the vector  $(\mathcal{A}(\kappa) - zI)^{-1}Y$ , with  $Y = (y, 0, \dots, 0) \in \mathbb{C}^{N(s+1)}$  and  $y \in \mathbb{C}^N$ . Indeed, let  $X = (x_0, \dots, x_s) \in \mathbb{C}^{N(s+1)}$  be the unique solution to  $(\mathcal{A}(\kappa) - zI)X = Y$ . We have:

$$\begin{aligned} \forall \sigma = 0, \dots, s, \quad x_\sigma &= z^{s-\sigma} x_s, \\ \left( I - \sum_{\sigma=0}^s z^{-\sigma-1} \widehat{Q}_\sigma(\kappa) \right) x_s &= -z^{-s-1} y. \end{aligned}$$

We have the estimate  $(|z| - 1)|X| \leq C|y|$  so in particular, we have  $(|z| - 1)|x_0| \leq C|y|$ . Using the relation  $x_0 = z^s x_s$ , we get an estimate:

$$|x_s| \leq \frac{C|z|^{-s}}{|z| - 1} |y|, \quad \text{where } x_s = -z^{-s-1} \left( I - \sum_{\sigma=0}^s z^{-\sigma-1} \widehat{Q}_\sigma(\kappa) \right)^{-1} y.$$

Taking the supremum over  $y \in \mathbb{C}^N$ , we obtain that there exists a constant  $C > 0$  such that:

$$\forall \kappa \in \mathbb{S}^1, \quad \forall z \in \mathcal{U}, \quad \left\| \left( I - \sum_{\sigma=0}^s z^{-\sigma-1} \widehat{Q}_\sigma(\kappa) \right)^{-1} \right\| \leq C \frac{|z|}{|z| - 1}. \quad (36)$$

We also easily compute the relation:

$$I - \sum_{\sigma=0}^s z^{-\sigma-1} \widehat{Q}_\sigma(\kappa) = \sum_{\ell=-r}^p \kappa^\ell \mathbb{A}_\ell(z), \quad (37)$$

where the matrices  $\mathbb{A}_\ell(z)$  are defined by (7).

Let  $\kappa \in \mathbb{S}^1$  and let  $z \in \mathcal{U}$ . We consider a vector  $b = (b_p, \dots, b_{-r+1}) \in \mathbb{C}^{N(p+r)}$  and we let  $x = (x_{p-1}, \dots, x_{-r})$  be the unique solution to  $(\mathbb{M}(z) - \kappa I)x = b$ . From the definition (8), we obtain the relations:

$$\begin{aligned} \forall \ell = -r + 1, \dots, p - 1, \quad x_\ell &= \kappa^{r+\ell} x_{-r} + \sum_{j=0}^{\ell+r-1} \kappa^j b_{\ell-j}, \\ \kappa^r \left( \sum_{\ell=-r}^p \kappa^\ell \mathbb{A}_\ell(z) \right) x_{-r} &= -\tilde{b}(\kappa, z), \end{aligned}$$

with a vector  $\tilde{b}(\kappa, z)$  defined by:

$$\tilde{b}(\kappa, z) := \mathbb{A}_p(z) b_p + \sum_{\ell=-r+1}^{p-1} \mathbb{A}_\ell(z) \sum_{j=0}^{\ell+r-1} \kappa^j b_{\ell-j} + \kappa \mathbb{A}_p(z) \sum_{j=0}^{p+r-2} \kappa^j b_{p-1-j}.$$

For  $z \in \mathcal{U}$  and  $\kappa \in \mathbb{S}^1$ , we have a uniform bound:

$$|\tilde{b}(\kappa, z)| \leq C|b|,$$

because the matrices  $\mathbb{A}_\ell(z)$  are uniformly bounded for  $z \in \mathcal{U}$ , see (7). We then use the relation (37) and the estimate (36) to obtain an upper bound for  $|x_{-r}|$ :

$$|x_{-r}| \leq C \frac{|z|}{|z| - 1} |b|,$$

with a constant  $C$  that is uniform with respect to  $\kappa \in \mathbb{S}^1$  and  $z \in \mathcal{U}$ . The other components  $x_{-r+1}, \dots, x_{p-1}$  of  $x$  are easily estimated in terms of  $x_{-r}$  and  $b$ . We have thus proved that there exists a constant  $C > 0$  such that for all  $z \in \mathcal{U}$  and for all  $\kappa \in \mathbb{S}^1$ , we have:

$$|(\mathbb{M}(z) - \kappa I)^{-1} b| \leq C \frac{|z|}{|z| - 1} |b|.$$

The proof of Lemma 2 is complete.

## B Proof of Lemma 6

We already know that  $\mathcal{L}(E)$  is a Banach space and that the set of isomorphisms  $Gl(E)$  is an open subset of  $\mathcal{L}(E)$ . This first property shows that the set  $\{t \in \mathcal{T} / L(t) \in Gl(E)\}$  is open because  $L$  is continuous. It only remains to show that this set is closed and the claim will follow (this set is nonempty thanks to the assumption of Lemma 6). We thus consider a sequence  $(t_n)$  in  $\mathcal{T}$  that converges to some  $\underline{t} \in \mathcal{T}$  and such that for all  $n$ ,  $L(t_n)$  belongs to  $Gl(E)$ . We are going to show that  $L(\underline{t})$  also belongs to  $Gl(E)$ . Using the Banach isomorphism Theorem, it is enough to prove that  $L(\underline{t})$  is a bijection.

Due to the uniform bound  $|x|_E \leq C_0 |L(t) x|_E$ , it is clear that  $L(t)$  is injective and that for all  $n$  we have  $\|L(t_n)^{-1}\|_{\mathcal{L}(E)} \leq C_0$ . It remains to show that  $L(\underline{t})$  is surjective. Let  $y \in E$ . For all integers  $n$  and  $p$ , we have:

$$\begin{aligned} |L(t_{n+p})^{-1} y - L(t_n)^{-1} y|_E &\leq \|L(t_{n+p})^{-1} - L(t_n)^{-1}\|_{\mathcal{L}(E)} |y|_E \\ &\leq \|L(t_{n+p})^{-1} (L(t_n) - L(t_{n+p})) L(t_n)^{-1}\|_{\mathcal{L}(E)} |y|_E \leq C_0^2 \|L(t_{n+p}) - L(t_n)\|_{\mathcal{L}(E)} |y|_E. \end{aligned}$$

These inequalities show that  $(L(t_n)^{-1} y)$  is a Cauchy sequence in  $E$  and therefore converges to some  $x \in E$ . Moreover we have  $L(t_n) L(t_n)^{-1} y = y$  for all  $n$  and passing to the limit we get  $L(\underline{t}) x = y$ . Here we use again the continuity of  $L$ . This shows that  $L(\underline{t})$  is surjective, which completes the proof.

## C An extension of Theorem 3

The aim of this appendix is to prove this extended version of Theorem 3:

**Theorem 4.** *Let assumption 1 be satisfied, and assume that the symbol  $\mathcal{A}(\kappa)$  is uniformly power bounded for  $\kappa \in \mathbb{S}^1$ . Assume moreover that all the eigenvalues of  $\mathcal{A}(\kappa)$ ,  $\kappa \in \mathbb{S}^1$ , that belong to  $\mathbb{S}^1$  are geometrically regular and that at least one of the four following properties is satisfied by each eigenvalue  $\lambda_j(\kappa)$  in the decomposition (10):*

- i)  $\lambda_j'(\underline{\kappa}) \neq 0$ ,
- ii)  $\lambda_j(\kappa) \in \mathbb{S}^1$  for all  $\kappa \in \mathbb{S}^1 \cap \mathcal{W}$ ,
- iii)  $\operatorname{Re}(\underline{\kappa}^2 \overline{\lambda_j(\underline{\kappa})} \lambda_j''(\underline{\kappa})) > 0$ .

*iv)*  $\underline{\kappa}^2 \overline{\lambda_j(\underline{\kappa})} \lambda_j''(\underline{\kappa}) \in i\mathbb{R} \setminus \{0\}$  and  $\operatorname{Re} \left[ \overline{\lambda_j(\underline{\kappa})} (\underline{\kappa}^4 \lambda_j^{(4)}(\underline{\kappa}) + 6 \underline{\kappa}^3 \lambda_j'''(\underline{\kappa})) \right] + 3 |\lambda_j''(\underline{\kappa})|^2 < 0$ .

Then  $\mathbb{M}$  defined by (8) admits a  $K$ -symmetrizer. In particular, if the uniform Kreiss-Lopatinskiĭ condition is satisfied, the scheme (2) is strongly stable.

*Proof.* We follow the proof of Theorem 3. In the block decomposition of  $\mathbb{M}(z)$ , we can have some new  $2 \times 2$  blocks that are associated with an eigenvalue  $\lambda_j$  of  $\mathcal{A}$  satisfying condition *iv)* in Theorem 4. We thus only need to show that we can construct a  $K$ -symmetrizer for a  $2 \times 2$  matrix  $P(z)$  that satisfies:

$$\det(P(z) - \kappa I) = \vartheta(\kappa, z) (z - \lambda(\kappa)), \quad P(\underline{z}) = \underline{\kappa} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$

where  $\lambda$  is holomorphic in a neighborhood of  $\underline{\kappa}$  and satisfies condition *iv)* in Theorem 4. Let us begin with the following:

**Lemma 9.** *Let  $\underline{\kappa} = e^{i\underline{\xi}}$  and let us define the holomorphic function  $\ell(\zeta) := \ln[\lambda(e^\zeta)/\underline{z}]$  for  $\zeta$  close to  $i\underline{\xi}$ . Then we have:*

$$\ell'(i\underline{\xi}) = 0, \quad \ell''(i\underline{\xi}) \in i\mathbb{R} \setminus \{0\}, \quad \ell'''(i\underline{\xi}) \in \mathbb{R}, \quad \operatorname{Re} \ell^{(4)}(i\underline{\xi}) < 0.$$

The proof of Lemma 9 follows from the assumptions on  $\lambda$  and from straightforward computations so we omit it. As in the proof of Theorem 3, we can define a matrix  $\mathbb{P}(\tau)$  that depends holomorphically on  $\tau$  in a neighborhood of 0 and such that  $P(z) = \exp \mathbb{P}(\ln(z/\underline{z}))$ . The lower left coefficient of  $\mathbb{P}'(0)$  is nonzero thanks to (30) so we have:

$$\det(\mathbb{P}(\tau) - \zeta I) = \vartheta(\zeta, \tau) (\tau - \ell(\zeta)),$$

where  $\ell$  is defined in Lemma 9. Moreover, there exists a holomorphic change of basis  $Q(\tau)$  such that:

$$\check{\mathbb{P}}(\tau) := Q(\tau)^{-1} \mathbb{P}(\tau) Q(\tau) = \begin{pmatrix} i\underline{\xi} & i \\ 0 & i\underline{\xi} \end{pmatrix} + \begin{pmatrix} b_1(\tau) & 0 \\ b_2(\tau) & 0 \end{pmatrix}, \quad (38)$$

where both functions  $b_1, b_2$  vanish for  $\tau = 0$ . Using Lemma 9 and differentiating four times the relation:

$$(\zeta - i\underline{\xi})^2 = (\zeta - i\underline{\xi}) b_1(\ell(\zeta)) + i b_2(\ell(\zeta)),$$

we obtain the following result:

$$b_2'(0) \in \mathbb{R} \setminus \{0\}, \quad b_1'(0) \in \mathbb{R}, \quad b_2''(0) \operatorname{Re} b_2''(0) < 0. \quad (39)$$

Then the proof of Theorem 4 follows from:

**Lemma 10.** *Let  $\check{\mathbb{P}}$  denote the matrix in (38) and let the functions  $b_1, b_2$  satisfy (39). Let  $K \geq 1$ . Then there exist a neighborhood of 0, a  $\mathcal{C}^\infty$  mapping  $\check{S}$  defined on this neighborhood with values in  $\mathcal{M}_2(\mathbb{C})$ , and there exists a constant  $c > 0$  such that for all  $\tau$  close to 0 the following properties hold:*

- $\check{S}(\tau)$  is hermitian,
- $\operatorname{Re} (\check{S}(\tau) \check{\mathbb{P}}(\tau)) \geq c (\operatorname{Re} \tau + (\operatorname{Im} \tau)^2) I$  if  $\operatorname{Re} \tau \geq 0$ ,
- for all  $W \in \mathbb{C}^2$ ,  $W^* \check{S}(0) W \geq (K^2 + 1/2) |W_2|^2 - |W_1|^2/2$ .

Using Lemma 10, the proof of Theorem 4 follows with the same arguments as used in the proof of Theorem 3. We thus focus on the proof of Lemma 10. For future use, we introduce the notations:

$$\alpha_1 := b_1'(0), \quad \alpha_2 := b_2'(0), \quad \beta := -\frac{b_2''(0)}{\alpha_2}.$$

From (39) the number  $\beta$  has positive real part. As in the proof of Lemma 8, we use the notation  $\tau = \gamma + i\delta$ . We can write:

$$b_1(i\delta) = i\alpha_1\delta + \delta^2 g_1(\delta), \quad b_2(i\delta) = i\alpha_2\delta + \alpha_2\beta\delta^2 + \delta^3 g_2(\delta),$$

for some appropriate analytic functions  $g_1, g_2$ . The symmetrizer  $\check{S}$  is chosen under the form:

$$\check{S}(\tau) = \check{S}_0(\delta) + \gamma \check{S}_1,$$

where  $\check{S}_0$  is a  $\mathcal{C}^\infty$  function of the real variable  $\delta$ , and  $\check{S}_1$  is a constant hermitian matrix. The matrix  $\check{S}_0(\delta)$  is chosen under the form:

$$\check{S}_0(\delta) := \begin{pmatrix} \alpha_2(\alpha_1 + b)\delta & \alpha_2 + ie\delta^2 \\ \alpha_2 - ie\delta^2 & b \end{pmatrix},$$

where  $b, e$  are real constants. We first fix  $b > 0$  sufficiently large so that the following estimate holds:

$$W^* \check{S}_0(0) W \geq (K^2 + \frac{1}{2}) |W_2|^2 - \frac{1}{2} |W_1|^2.$$

With our choice for  $\check{S}_0$ , we compute:

$$\operatorname{Re} (\check{S}_0(\delta) \check{P}(i\delta)) = \delta^2 \begin{pmatrix} \alpha_2^2 \operatorname{Re} \beta & \star \\ \frac{\alpha_2}{2} (b\beta + g_1(0)) & e \end{pmatrix} + O(\delta^3),$$

where the  $\star$  coefficient is such that the matrix above is hermitian. We can then choose  $e$  large enough such that for all  $\delta$  sufficiently small, we have:

$$\operatorname{Re} (\check{S}_0(\delta) \check{P}(i\delta)) \geq c\delta^2 I,$$

for some appropriate constant  $c > 0$ . The construction of  $\check{S}$  is then achieved, as in Lemma 8, by taking:

$$\check{S}_1 := \begin{pmatrix} 0 & ig \\ -ig & 0 \end{pmatrix},$$

with  $g > 0$  sufficiently large. The proofs of Lemma 10 and consequently of Theorem 4 are complete.  $\square$
