HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Carnets de Géologie (2009: Special Publication 1)

Dasycladales are unicellular green algae in existence since the Paleozoic era. Dasycladales discovered in the Cenozoic strata of the French sedimentary basins (Fig. 1) are noteworthy for the exceptional quality of their preservation. Although most fossil Dasycladales are known only in thin sections, the coatings of the Dasycladales in these basins, particularly of those in Lutetian beds, are easy to extract from sandy sediments and then are examined under the electron microscope. This method of investigation facilitates greatly the identification of the external and internal features of each species.

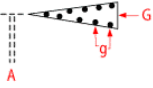

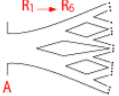

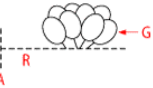

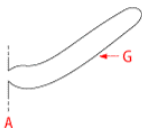

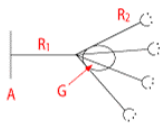

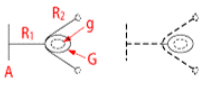

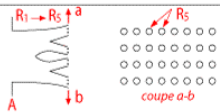

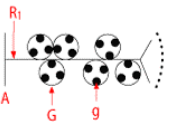

Figure 1: Paleogeographical map of France during Lutetian and main sites of discoveries (red circles).

GENERA	MAIN MORPHOLOGICAL FEATURES OBSERVED ON FOSSILS	SHAPE OF THE THALLUS	SCHEMATIC ASPECT OF THE ORGANS
Acicularia	Isolated or associated elongated gametophores (spicules) arranged radially. Numerous gametangia (cysts) embedded into a lime matrix filling the gametophores.		
Belzungia	Up to six orders of slender lateral segments. Last orders irregularly arranged inside the wall. Reproductive organs unknown.		
Carpenterella	Gametophores clustered in tufts (probably located along the sides of the laterals).		
Clypeina	Superposed crowns of tubes interpreted as gametophores arranged radially..		
Cymopolia	Segmented thallus. Two orders of lateral segments in fertile whorls. The top of each primary lateral segment bears numerous secondary laterals surrounding a gametophore. No cyst.		
Dameryella	Unilocular calcareous corpuscles considered as isolated gametophores.	unknown	
Frederica	Isolated corpuscles considered as gametophores containing numerous gametangia (cysts) joined side by side at the inner periphery.	unknown	
Neomeris	Two orders of lateral segments. The top of each primary lateral segment bears two secondary lateral segments surrounding a gametophore. Uncalcified cyst in each gametophore in living Neomeris, never observed on fossils.		
Thyrsoporella	Up to five orders of thick lateral segments, regularly arranged inside the wall. Reproductive organs unknown.		
Zittelina	Rounded or irregular gametophores arranged along the sides of the lateral segments. Calcification surrounds several gametangia (cysts) inside each gametophore.		

Dasycladales flourished during the Lutetian because conditions for their development were optimal during this epoch: hot climate and shallow marine water environments. The richest communities are composed of 13 to 18 species discovered in the Middle Lutetian sediments of the Paris Basin, in the Yvelines department (La Ferme de l'Orme, Grignon, Septeuil, Villiers-Saint-Frédéric) and in the Upper Lutetian sediments of Campbon and Saffré Basins, in the south of Brittany, Loire-Atlantique department (Fig. 1).

The preservation of the Dasycladales as fossils depends on the degree to which the original calcification covered living parts of the alga.

The extent of the calcification may vary greatly from one species to another of the same genus, sometimes even between individuals of a species. Of the Lutetian species illustrated in this photo-atlas, some have a calcification that envelops almost all the vegetative and reproductive organs (*Neomeris larvarioides*, *Cymopolia armorica*, *Cy. elongata*, *Cy. turgescens*, *Zittelina rotunda*), while in others calcification is restricted to a group of reproductive organs (cluster of gametophores in *Carpenterella jonesi*, whorl of tubular gametophores in *Clypeina marginiporella*, *Cl. stelliformis*) or to laterals (*Belzungia terquemi*, *Thyrsoporella cancellata*). In *Neomeris*, the calcification is particularly variable from one species to another: the two orders of laterals and the gametophores are strongly calcified in *Neomeris larvarioides*; the

◀ **Figure 2:** Main morphological features of the genera of which species are present in the Lutetian sediments of the French sedimentary basins.

gametophores are completely calcified but the laterals only partially in *N. filiformis*, *N. fragilis*, *N. pustulosa*, *N. radiata* and *N. reticulata*; the laterals are uncalcified but the gametophores are strongly calcified in *N. bipartita* and *N. limbata*. To conclude, some species are known only as elongated isolated spicules (pluricyclic gametophores of *Acicularia acuminata*, *A. cornigera*, *A. pavantina*), elongated associated spicules (pluricyclic gametophores of *Acicularia costulata*, *A. heberti*, *A. munieri*) or sphaerical to ovoid isolated corpuscles (pluricyclic gametophores in *Frederica villiersi*, gametophores without cysts in *Dameryella tuberosa*).

Systematic classification:

Section: Chlorophyta

Class: Ulvophyceae (Dasycladophyceae)

Order: Dasycladales PASCHER, 1931

Illustrated species:

Acicularia acuminata GENOT, 1989

Acicularia cornigera L. & J. MORELLET, 1922

Acicularia costulata GENOT, 1987

Acicularia heberti L. & J. MORELLET, 1922

Acicularia munieri L. & J. MORELLET, 1913

Acicularia pavantina d'ARCHIAC, 1843

Belzungia terquemi L. & J. MORELLET, 1917

Carpenterella jonesi L. & J. MORELLET, 1922

Clypeina marginiporella MICHELIN, 1845

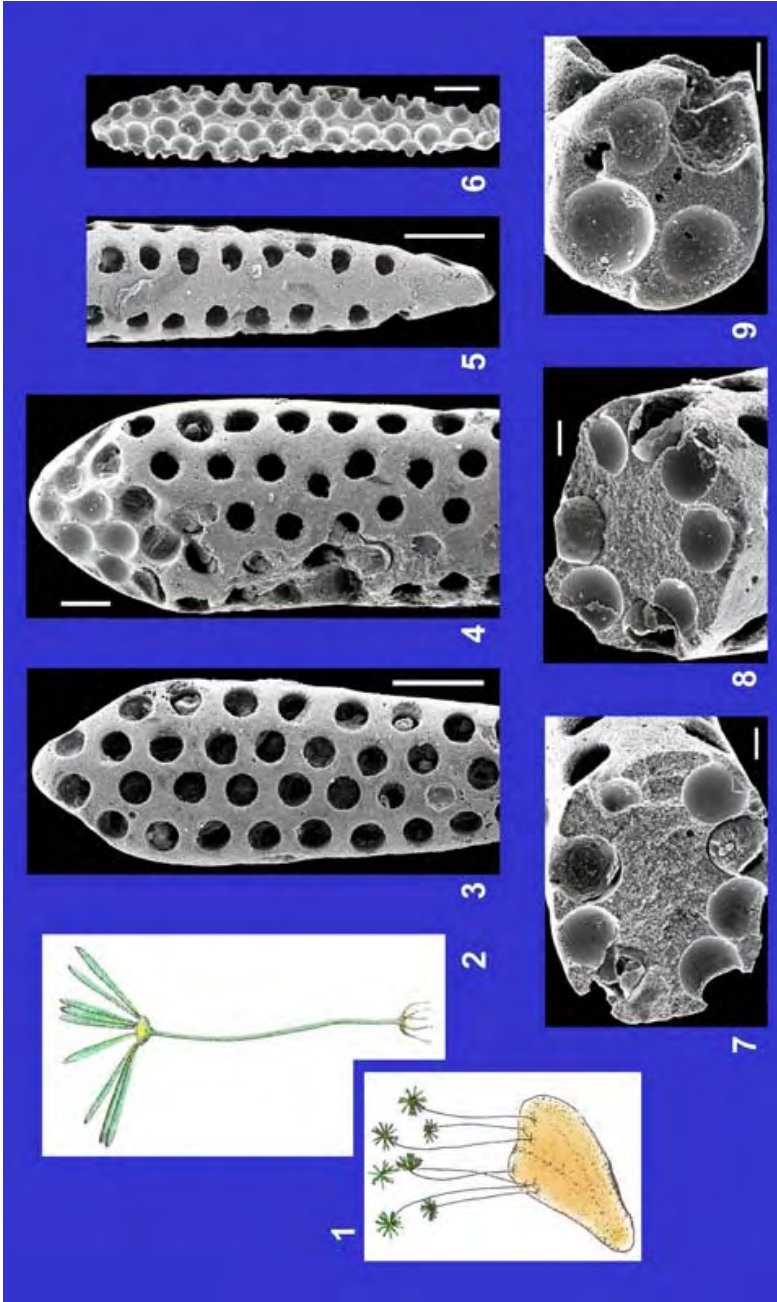

Clypeina stelliformis L. & J. MORELLET, 1939

Cymopolia armorica GENOT, 1987

Cymopolia elongata (DEFRANCE, 1825) MUNIER-CHALMAS, 1877

Cymopolia turgescens GENOT, 1987
Dameryella tuberosa BIGNOT & GENOT, 1998
Frederica villiersi BARTA-CALMUS, 1966
Neomeris bipartita GENOT, 1987
Neomeris fercourtensis GENOT, 1980
Neomeris filiformis (L. & J. MORELLET, 1913) PIA, 1927
Neomeris fragilis (DEFRANCE, 1825) L. & J. MORELLET, 1913
Neomeris larvarioides (L. & J. MORELLET, 1913) GENOT, 1980
Neomeris limbata (DEFRANCE, 1822) PIA, 1927
Neomeris pustulosa L. & J. MORELLET, 1917
Neomeris radiata L. & J. MORELLET, 1922
Neomeris reticulata (DEFRANCE, 1822) PIA, 1927
Thyrsoporella cancellata GÜMBEL, 1872
Zittelina dumasi (L. & J. MORELLET, 1917) PIA, 1927
Zittelina elegans L. & J. MORELLET, 1913
Zittelina parisiensis (L. & J. MORELLET, 1922) PIA, 1927
Zittelina rotunda (GENOT, 1980) GENOT, 1987

More informations and detailed descriptions concerning Lutetian Dasycladales of the French sedimentary basins are in the papers of L. & J. MORELLET (1913, 1917, 1922) and GÉNOT (1978, 1980, 1987). Features of some Cenozoic species belonging to the genera *Cymopolia*, *Neomeris* and *Acicularia* are close to those of Recent species: the publications of VALET (1968, 1969), BERGER (2006), BERGER and KAEVER (1992) are useful for the interpretation of fossil specimens and for making comparative studies.

Acicularia acuminata GÉNOT, 1989

Description and more illustrations in: GÉNOT, 1987, p. 160, Pl. 10, fig. 14, Pl. 20, figs. 1-13; 1989, Pl. 1, figs. 7-11.

***Neomeris fercourtensis* GÉNOT, 1980**

Middle Lutetian, Fercourt (Oise), Paris Basin.

Description and other illustrations: GÉNOT, 1980, Pl. 7, figs. 7-12, Pl. 10, figs. 9-10, Pl. 11, figs. 7-8, Pl. 12, fig. 6.

Plate 17

1. Schematic reconstruction of the general shape of the thallus.
2. External view with the typical alveolated aspect of the surface. Scale: 100 μm .
- 3-4. Internal surfaces and longitudinal sections of the wall across some gametophores and secondary lateral segments. Primary lateral segments are not calcified. Scales: 100 μm .

4

Neomeris filiformis
(L. & J. MORELLET, 1913) PIA, 1927

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 17, Pl. 1, figs. 52-53; GÉNOT, 1980, Pl. 16, figs. 1-9, Pl. 18, figs. 5-6, Pl. 19, figs. 8-9, Pl. 20, fig. 5.

Plate 18

1. Schematic reconstruction of the general shape of the thallus.
2. External view with the typical alveolated aspect of the surface. Middle Lutetian, Chaussy (Oise), Paris Basin. Scale: 200 μm .
3. Transverse section with the location of the secondary lateral segments (primary segments are not calcified). Middle Lutetian, Damery (Marne), Paris Basin. Scale: 100 μm .
4. Transverse section with the location of the gametophores. The central cavity is narrow. Middle Lutetian, Chaussy (Oise), Paris Basin. Scale: 50 μm .
5. Longitudinal section with sections of the gametophores and external view of the basal end of the sheath. Middle Lutetian, Chaussy (Oise), Paris Basin. Scale: 100 μm .
6. Longitudinal section and internal surface presenting alternate swellings (envelopes of gametophores) and circular furrows (location of secondary lateral segments: rounded pores). Middle Lutetian, Chaussy (Oise), Paris Basin. Scale: 100 μm .
7. Tangential section with alternation of rows of large rounded cavities (gametophores) and rows of small pores (secondary segments partially calcified). Middle Lutetian, Damery (Marne), Paris Basin. Scale: 100 μm .

Neomeris fragilis
(DEFRANCE, 1825) L. & J. MORELLET, 1913

Middle Lutetian, Grignon (Yvelines), Paris Basin.

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 20, Pl. 2, figs. 15-19; GÉNOT, 1980, Pl. 6, figs. 1-9, Pl. 10, figs. 7-8, Pl. 11, fig. 9, Pl. 12, figs. 4-5; 1987, Pl. 1, figs. 1-2.

Plate 19

1. Schematic reconstruction of the general shape of the thallus.
2. External view with the alveolated surface (calcification of distal ends of the secondary lateral segments) and transverse section showing the calcification of the stem. Scale: 500 μm .
3. Detail of the external surface. Scale: 100 μm .
4. Internal surface with the calcification of the gametophores (small circular pores represent the location of the peduncles). Very irregular pores correspond to the location of the secondary lateral segments, very partially and irregularly calcified. Scale: 100 μm .
5. Detail of a transverse section with 2 gametophores. Scale: 100 μm .
6. A gametophore with its short peduncle. Scale: 50 μm .
7. Reconstruction of a gametophore and hypothetical reconstruction of the lateral segments (lateral segments are almost not calcified in this species). Drawing: Robert DUFOUR.

6

Neomeris larvarioides
(L. & J. MORELLET, 1913) GÉNOT, 1980

Upper Lutetian, Le Bois-Gouët (Loire-Atlantique), Brittany.

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 13, Pl. 1, figs. 41-42; GÉNOT, 1980, Pl. 8, figs. 1-10; 1987, Pl. 10, figs. 1-3, Pl. 33, figs. 1-13.

Plate 20

1. Schematic reconstruction of the general shape of the thallus.
- 2-3. Different aspects of the sheath. Pores are the location of the secondary lateral segments. Scales: 500 μm (fig. 2) and 200 μm (fig. 3).
4. Internal aspect and longitudinal section of the wall with the 2 orders of laterals and the gametophores. Scale: 200 μm .
5. Longitudinal section. Calcification surrounds the laterals and the gametophores. Scale: 100 μm .
6. Reconstruction of a gametophore surrounded by the 2 orders of laterals. Drawing: Robert DUFOUR.

3

Neomeris limbata
(DEFRANCE, 1822) PIA, 1927

EOCENE	PRIABONIAN
	BARTONIAN
	LUTETIAN
	YPRESIAN
PALEOCENE	THANETIAN

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 14, Pl. 1, figs. 25-35; GÉNOT, 1980, Pl. 14, figs. 1-12, Pl. 18, figs. 9-11, Pl. 19, figs. 4-5, 10.

Plate 21

1. Schematic reconstruction of the general shape of the thallus.
2. Superposed rings corresponding to the calcification of 3 circular rows of gametophores. Pores between rings are the location of the secondary lateral segments, almost not preserved. Middle Lutetian, Saint-Lubin-de-la-Haye (Eure), Paris Basin. Scale: 100 µm.
- 3-5. Different aspects of the ornamentation on the lower side of rings. Each unit corresponds to the calcification of a gametophore. Pores of the inner periphery are the location of peduncles. 3: Middle Lutetian, La Ferme de l'Orme (Yvelines), Paris Basin. 4: Upper Lutetian, Le Bois-Gouët (Loire-Atlantique), Brittany. 5: Middle Lutetian, Saint-Lubin-de-la-Haye (Eure), Paris Basin. Scales: 100 µm.
6. Upper side of a ring. Middle Lutetian, Saint-Lubin-de-la-Haye (Eure), Paris Basin. Scale: 100 µm.
7. Longitudinal section of a ring crossing 2 gametophores. Middle Lutetian, Saint-Lubin-de-la-Haye (Eure), Paris Basin. Scale: 100 µm.
8. Circular row of gametophores inside a ring. Middle Lutetian, La Ferme de l'Orme (Yvelines), Paris Basin. Scale: 100 µm.

***Neomeris pustulosa* L. & J. MORELLET, 1917**

Upper Lutetian, Le Bois-Gouët (Loire-Atlantique), Brittany.

Description and other illustrations: L. & J. MORELLET, 1917, p. 366, Pl. 14, figs. 4-6; GÉNOT, 1987, Pl. 10, figs. 4-5; Pl. 34, figs. 1-12.

Plate 22

1-2. External aspects of articles. Scales: 500 μm (fig. 1) and 200 μm (fig. 2).

3-4. Longitudinal sections of articles crossing gametophores and rare secondary lateral segments. Scales: 100 μm .

1

2

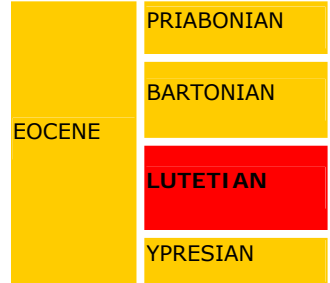

4

***Neomeris radiata* L. & J. MORELLET, 1922**

Middle Lutetian, Liancourt-Saint-Pierre (Oise), Paris Basin (except fig. 2: Fercourt (Oise)).

Main references with description and illustrations: L. & J. MORELLET, 1922, p. 14, Pl. 1, figs. 33-37; GÉNOT, 1980, Pl. 7, figs. 1-6, Pl. 10, figs. 5-6, Pl. 11, figs. 5-6, Pl. 12, fig. 3.

Plate 23

1. Schematic reconstruction of the general shape of the thallus.
2. External aspect of the sheath. Pores are the location of the secondary lateral segments. Scale: 200 μm .
3. Detail of the external surface. Each unit is the calcification of a gametophore. The wall surface is perforated by numerous small pores of irregular shape. Large pores correspond to the location of secondary lateral segments, partially calcified. Scale: 100 μm .
4. Internal surface with superposed rings, each corresponding to the calcification of a circular row of gametophores. Secondary laterals are located between these rings. Scale: 100 μm .
5. Two superposed rings. Rows of small rounded pores, located at the inner periphery of the rings, are the proximal ends of the peduncles of gametophores. Scale: 100 μm .
6. Longitudinal section crossing gametophores and some secondary lateral segments. Scale: 100 μm .

2

3

5

6

Neomeris reticulata
(DEFRANCE, 1822) PIA, 1927

Middle Lutetian, Grignon (figs. 3-4, 6) and La Ferme de l'Orme (figs. 2, 5, 7), Yvelines, Paris Basin.

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 14, Pl. 1, figs. 36-40; GÉNOT, 1980, Pl. 15, figs. 1-9, Pl. 18, figs. 3-4, Pl. 19, figs. 6-7, Pl. 20, figs. 3-4.

Plate 24

1. Schematic reconstruction of the general shape of the thallus.
2. External aspect of the sheath. The calcified envelopes of the gametophores look like associated rounded corpuscles. Scale: 200 μm .
3. External aspect of a strongly calcified specimen. Pores are the location of the secondary lateral segments, partially calcified. Scale: 100 μm .
4. Internal surface of the sheath. Each ring corresponds to the calcification of a circular row of gametophores. Rows of gametophores are irregularly calcified. Secondary laterals are located between the rings. Scale: 100 μm .
5. Longitudinal section and internal surface of a weakly calcified specimen. Scale: 100 μm .
6. Longitudinal section, crossing gametophores and secondary laterals, and internal surface of a strongly calcified specimen. Scale: 100 μm .
7. Detail of the longitudinal section crossing a gametophore. Scale: 50 μm .

Thyrsoporella cancellata GÜMBEL, 1872

Main references with description and illustrations: L. & J. MORELLET, 1913, p. 37, Pl. 3, figs. 32-34; MASSIEUX, 1966, p. 136, Pl. 1, figs. 1-6; GÉNOT, 1980, Pl. 25, figs. 4-7.

Plate 25

1. Schematic reconstruction of the general shape of the thallus.
2. External aspect of the sheath. Each plate has 32 pores which correspond to the last order laterals, with 4 horizontal and 8 vertical rows of pores. Middle Lutetian, Châteaurouge (Oise), Paris Basin. Scale: 100 μm .
3. Detail of the external surface with the rows of the last order laterals. Middle Lutetian, Fercourt (Oise), Paris Basin. Scale: 50 μm .
4. Transverse section showing the large main axis and the division of the laterals inside the wall. Middle Lutetian, Fercourt (Oise), Paris Basin. Scale: 100 μm .
5. Longitudinal section. Middle Lutetian, Fercourt (Oise), Paris Basin. Scale: 100 μm .
6. Detail of the internal surface. One primary lateral segment (large oval pore) branches into 2 secondary laterals separated by a vertical septum. Middle Lutetian, Châteaurouge (Oise), Paris Basin. Scale: 20 μm .
7. Oblique section crossing several orders of laterals inside the wall. Middle Lutetian, Châteaurouge (Oise), Paris Basin. Scale: 20 μm .

Acknowledgments

The microphotographs were taken at the University of Nantes, with the practical help of Alain BARREAU. I am indebted to Alain COSSARD for the realization of the slides and to Robert DUFOUR and Philippe CORBARD for the drawings. All my particular thanks to Bruno GRANIER who made this publication possible and to Ioan I. BUCUR and Filippo BARATTOLO for their help in improving the manuscript.
