HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract: This paper addresses the problem of forbidden states for safe Petri net modeling discrete event systems. We present an efficient method to construct a controller. A set of linear constraints allow forbidding the reachability of specific states. The number of these so-called forbidden states and consequently the number of constraints are large and lead to a large number of control places. A systematic method for constructing very simplified controller is offered. By using a method based on Petri nets partial invariants, maximal permissive controllers are determined.

Keywords: Discrete Event Systems (DES), Petri Nets, Supervisory control, Controller synthesis, Forbidden states

1. INTRODUCTION

A unifying framework for the control of discrete event systems is provided by Ramadge and Wonham (1987, 1989), and so far their supervisory control theory is the most general and comprehensive theory presented for logical DES. In Ramadge & Wonham (1987, 1989), it is shown that we can model the systems by using of formal languages and finite automata. Methods exist for designing controllers based on automata system models, however these methods often involve exhaustive searches or simulations of the system behaviour, making them impractical for systems with large numbers of states and transitions causing event (Moody, Antsaklis 2000). For solving these problems, we can model systems with Petri nets (PNs).

Petri nets are a very appropriate and useful tool for the study of discrete event systems because of their modelling power and their mathematical properties. In the last decade, the research in the field of controller synthesis of discrete event systems has become one of the most active domains (Achour et al. 2004; Giua A & Xie X., 2005).

In Giua et al., (1992) it is shown that it is possible to represent the forbidden states with linear constraints. With the idea presented by Yamalidou et al. (1996) we can design a controller by adding a control place to the PN mode. Each control place corresponds to a constraint. However, when the number of forbidden states is large, then the number of constraints has the same size. In Giua (1992b) it is shown that we can simplify some constraints. But there is no systematic method for simplifying these constraints in general case. This simplification is done by using the PNs structural properties. In Dideban and Alla (2005) a systematic method for reducing the size and the number of constraints was introduced. It was applicable for safe and conservative PNs.

In Dideban and Alla (2008), an efficient method for constructing a controller based on safe PN is presented. A set of linear constraints allow forbidding the reachability of specific states. The number of these so-called forbidden states, and consequently the number of constraints are large and lead to a large number of control places. A systematic method for reducing the size and the number of constraints for safe PN was introduced there. With applying the idea in Dideban & Alla (2008), it is possible that sometimes the final number of constraints may remain large. In this paper our objective is to develop the idea in Dideban & Alla (2008) and to present a systematic method for safe PN which allows to do more simplification than in the previous approaches.

In this paper, we introduce the concept of Partial Place invariant and then, we present the simplification method. We apply this method to a concrete example to highlights its advantages. We use constraints which are equivalent to forbidden states. These constraints can be calculated in two different ways. They can be given directly as specifications or they can be deduced thanks to the Kumar approach (Kumar & Holloway, 1996).

By applying the idea in Dideban & Alla (2008) and the new approach, it is possible to make a powerful simplification. The advantage of the new idea is to reduce more the number of forbidden states.

This paper is organized as follows: in section 2, some important definitions are introduced. In section 3, the idea of passage from forbidden states to linear constraints will be introduced. The idea in Dideban & Alla (2008) and a practical example are presented in section 4. The basic original idea of simplification and the calculation of control places are presented in section 5. Finally, the conclusion is given in the last section.

2. PRELIMINARY PRESENTATION

In this paper, it is supposed that the reader is familiar with the PNs basis (David & Alla, 2005) and the theory of supervisory control (Ramadge & Wonham, 1987, 1989). We briefly introduce the idea that was presented in (Dideban & Alla, 2008). For more detail, the reader can refer to this reference.
A PN is represented by a quadruplet \( R = \{ P, T, W, M_0 \} \), where \( P \) is the set of places, \( T \) is the set of transitions, \( W \) the incidence matrix and \( M_0 \) is the initial marking. Here we show the number of tokens in a place \( P_i \) with \( m_i \). The PN is assumed to be safe; then the marking of each place is Boolean.

\( M_B \) denotes the set of PN reachable markings. In \( M_B \), two subsets can be distinguished; the set of authorized states \( M_A \) and the set of forbidden states \( M_F \). The set of forbidden states correspond to two groups:

1. The set of reachable states \( M_B \) which either don’t respect the specifications or are deadlock states.
2. The set of states for which the occurrence of uncontrollable events leads to states in \( M_F \).

The set of authorized states are the reachable states without the set of forbidden states:

\[ M_A = M_B \setminus M_F \]

Among the forbidden states, an important subset is constituted by the border forbidden states denoted as \( M_B \) (Kumar & Holloway, 1996).

**Definition 1.** Let \( M_B \) be the set of border forbidden states:

\[ M_B = \{ M_j \in M_B \mid \exists \sigma \in \Sigma, \text{ and } \exists M_j \in M_B, M_j \xrightarrow{\sigma} M_i \} \]

Where \( \Sigma \) is the set of controllable transitions.

In this paper, we use the concept of support instead of marking as presented in definition 2.

**Definition 2.** The function \( \text{Support}(X) \) of a vector \( X \in \{0,1\}^n \) is the set of marked places in \( X \).

**Definition 3.** Let \( R \) be a PN, \( P \) the set of places, \( M_0 \) the set of reachable markings from \( M_0 \) and \( k \) a constant. A place invariant is obtained if there is a sub-set of places \( P_0 = \{ P_1, P_2, \ldots, P_r \} \) included in \( P \) and a weighing vector \( \{ q_1, q_2, \ldots, q_r \} \) for which all the weights \( q \) are positive integers such that:

\[ q_1 m_1 + q_2 m_2 + \ldots + q_r m_r = k \]

Then we say \( P_0 \) is a place invariant (David & Alla, 2005).

But if we remove some places from the set \( P_0 \), what happens? It follows the definition of partial invariant:

**Definition 4.** Let \( P = \{ P_1, P_2, \ldots, P_r \} \) be a place invariant in PN model \( R \), \( P_0 = \{ P_1, P_2, \ldots, P_k \} \) for which \( \{1,2,\ldots,L\} = \{1,2,\ldots,r\} \), is a partial place invariant and it satisfies the following equation:

\[ q_1 m_1 + q_2 m_2 + \ldots + q_k m_k \leq k, \forall m \in M_0 \]

### 3. Forbidden States to Linear Constraints

Let \( M_r(M_0, \Sigma) = \{ m_1, m_2, \ldots, m_n \} \) be a forbidden state in set \( M_0 \) and \( \text{Support}(M_0) = \{ P_1, P_2, \ldots, P_{r_m} \} \) the set of marked places of \( M_0 \). From a forbidden state, a linear constraint can be constructed (Giua et al., 1992).

The linear constraint deduced from the forbidden state \( M_0 \) is given below. The state \( M_0 \) does not verify this relation. Therefore, by applying this relation, \( M_0 \) will be forbidden.

\[ \sum_{i=1}^{n} m_i \leq n - 1 \]

Where \( n = \text{Card} [\text{Support}(M_0)] \), is the number of marked places of \( M_0 \), and \( m_i \) is the marking of place \( P_i \) of state \( M_0 \).

Let \( M(M_0, M_r) = \{ m_1, m_2, \ldots, m_n \} \) be a general marking and \( M_r \) be a forbidden state. The constraint (forbidden state) \( M_r \) is denoted by \( c_r \) and can be rewritten as follows:

\[ M_r = [M_r, \leq \text{Card} [\text{Support}(M_i)] - 1] \]

For example if:

\[ M_r = [0, 1, 0, 0, 0, 1] \Rightarrow \text{Card} [\text{Support}(M_i)] = 3 \]

\[ \Rightarrow m_1 + m_2 + m_3 \leq 2 \]

Verifying the relation in above is equivalent to forbidding state \( M_r \) when the PN model is conservative. However, in a safe PN not necessarily conservative, this equivalence is not always true.

In follow we recall the concept of over-state that was introduced in Dideban & Alla (2008).

**Definition 5.** Let \( M_0 = P_1 P_2 \ldots P_{2n} \) be an accessible state, \( M_1 = P_1 P_2 \ldots P_{2n} \) will be an over-state of \( M_0 \) if:

\[ M_1 \leq M_0 \]

That means all of the places in \( M_1 \) are in \( M_0 \). For example \( M_1 = P_2 P_3 \) is an over-state of \( M_0 = P_1 P_2 P_3 \).

The name over-state is used because the constraint corresponding to an over-state holds constraint. For example, the constraint \( m_1 + m_2 \leq 1 \) that is correspond to the over-state \( M_0 = P_1 P_2 P_3 \) holds both following constraints:

\[ m_1 + m_2 + m_3 + m_4 \leq 3 \]

These two constraints forbid states \( M_0 = P_1 P_2 P_3 \) and \( M_0 = P_2 P_3 P_1 \) which could be verified by \( M_1 \leq M_0 \) and \( M_2 \leq M_0 \). Thus by using only the constraint \( m_1 + m_2 \leq 1 \), both states \( M_2 \) and \( M_0 \) will be forbidden.

**Remark 1.** With each over-state \( b_n \), we associate a constraint \( c_n : b_n = (P_1 P_2 P_3 \ldots P_{2n}) \Rightarrow c_n = (P_1 P_2 P_3 \ldots P_{2n} - 1) \).

That means:

\[ m_1 + m_2 + \ldots + m_2n - 1 \]

The concept of over-state could be used for the reduction the number of constraints deducted from states or over-states (Dideban & Alla, 2008). In the next section we introduce these ideas and the problem to solve.

### 4. Recuption the Number of Constraints

Now we explain the idea in Dideban & Alla (2008). Suppose that in a system we have the set of authorized states \( M_A \) and the set of border forbidden states \( M_B \). In the first step of reduction, we must construct the sets \( B_0 \) (All the over-states of border forbidden states) and \( A_1 \), (All the over-states of authorized states). Then we remove from \( B_0 \), the states or over-states that exist in \( A_1 \) and call this set \( B_1 \). In the next step we remove the states which their over-states are in \( B_1 \), and we call it \( B_2 \).

Sometimes it is possible, to simplify the reduced set \( B_0 \), by application of the idea that is presented in Dideban (2007). But sometimes it is not the simplest set. The rules to choose the final over-states are similar to the rules of the Quine-McCluskey method to simplify the logical expressions (Morris Mano, 2001).

### 4.1. Introduction of a practical example
Consider a system with three machines and two robots. The closed loop PN model of this system is presented in fig. 1. The start command of each machine is accomplished by controllable transitions $c_1$, $c_2$, $c_3$ and the stop command is accomplished by uncontrollable transitions $f_1$, $f_2$, $f_3$. Two Robots are used to free three machines. All of machines can be turned on or off independently. The end of process for each machine when at least one of the robots are not free, is forbidden. From constructing the reachability graph, we can calculate the set of border forbidden states.

Fig. 1. closed loop PN model

Fig. 2. A part of reachability graph of the PN model presented in fig. 1. The construction of the reachability graph is stopped when a forbidden state is reached. The state after these forbidden states is presented by $\otimes$ .

As it is obvious in fig. 2, the existence of uncontrollable events leads to the forbidden states. For example when the system is in state $(P_1P_2P_3P_9P_{10})$, it is possible to fire the uncontrollable event $f_1$, while it is not authorized by the specifications. This state is called as a forbidden state. And the set of border forbidden states can be determined from these forbidden states. In this example the set of border forbidden states is:

$$\mathcal{M}_b = \{P_1P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}, P_1P_2P_3P_9P_{10}\}$$

Now, the sets of over-states of $\mathcal{M}_4$ and $\mathcal{M}_6$ are constructed. The set of over-states of $\mathcal{M}_6$ is shown with $\mathcal{B}_1$ and $\mathcal{M}_4$ with $\mathcal{A}_1$.

Hence the set of over-states of $\mathcal{M}_6$ is:

$$\mathcal{B}_1 = \{P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}, P_2P_3P_9P_{10}\}$$

Fig. 2. A part of reachability graph of the PN model

By the method presented in Dideban & Alla (2008), the controller can be synthesized by final selection of simplified over-states.

4.2. Controller synthesis

Final selection is similar to the McCluskey method for simplifying logical terms. In this method we construct a table (table 1) where the first row represents the set of border forbidden states $\mathcal{M}_b$, and the first column is the set of simplified over-states $\mathcal{B}_2$. The relation between border forbidden states and the simplified over-states can be expressed by the following definition:

**Definition 6.** Let $\mathcal{B}_2 = \{b_1, b_2, ..., b_n\}$ be the set of simplified over-states and $\mathcal{M}_b = \{M_1, M_2, ..., M_m\}$ be the set of border forbidden states. The relation $R : \mathcal{M}_b \times \mathcal{B}_2 \to \{0, 1\}$ is as:

$$R(M_i, b_j) = \begin{cases} 1 & b_j \leq M_i (b_j \text{ is over-state of } M_i) \\ 0 & \text{if not.} \end{cases}$$

The covering of a marking is an integer number:

$$Cv(M_i) = \sum R(M_i, b_j)$$

$Cv(M_i) \geq 1$ means that forbidden state $M_i$ is covered by at least one over-state.

**Table 1: Relation between over-states and border forbidden states**
The final constraints must cover all the forbidden states. This means that with applying the constraints equivalent to the final sets, all the border forbidden states are forbidden. These constraints are as follow:

\[ \mathcal{B}_i = \{ P_1 P_2 P_3, P_2 P_3 P_4, P_6 P_8 P_9, P_2 P_4 P_5 P_7 P_8, P_2 P_4 P_5 P_7 P_9, P_2 P_4 P_5 P_7 P_10, P_2 P_4 P_5 P_7 P_10, P_2 P_4 P_5 P_7 P_10, P_2 P_4 P_5 P_7 P_10, P_2 P_4 P_5 P_7 P_10, P_2 P_4 P_5 P_7 P_10, \}

Before using the method in Dideban & Alla (2008), the number of constraints and equivalently the number of forbidden states for our example was 13, but with using this method, the number of constraints is 9. It is clear that the number of simplified constraints is large, and for designing a controller by the method presented by Yamalidou et al. (1996), the number of control places is also large. However, is it possible to simplify these constraints more? The answer to this question is given by a method based on the concept of partial place invariant that was defined in section 2.

5. INTRODUCTION OF THE NEW IDEA FOR SIMPLIFICATION

We consider the partial invariant for safe and conservative PN. From the invariant relations we can construct partial invariants. For example:

\[ m_1 + m_2 + ... + m_{si} = k \quad \Rightarrow \quad m_1 + m_2 + ... + m_{si} \leq k \]

In safe PN in general case, it is not possible to construct this equation directly. In the following, we present some properties based on partial invariants that in many cases allow us to simplify the set of constraints representing the forbidden states.

Property 1: suppose that \( m_{ia}, m_{ia} \) are the number of tokens in the places \( P_i, P_j \) respectively. If \( P_i P_j \) is not in the set of over-states of authorized states we have:

\[ m_{i1} + m_{i2} \leq 1 \]

Proof: Suppose that the constraint is not true. Then we have:

\[ m_{i1} + m_{i2} > 1 \]

So, for safe PN we have:

\[ m_{i1} + m_{i2} = 2 \rightarrow m_{i3} = m_{i2} = 1 \]

This means \( P_i P_j \) is in the set of over-states of authorized states that is not true. Then: \( m_{i1} + m_{i2} \leq 1 \)

Property 2 (Extension of Property 1), suppose that the constraint \( m_{i1} + ... + m_{i6} \leq 1 \) is true. If all of the over- states \( \{P_i P_j P_{a(1)} \}, ... , \{P_i P_j P_{a(r)} \} \) are not in the set of over-states of authorized states, we have: \( m_{i1} + ... + m_{ia} + m_{i(a+1)} \leq 1 \)

Proof: The proof of this property is similar to the proof of property 1. Suppose that this relation is not true, so we can write:

\[ m_{i1} + ... + m_{ia} + m_{i(a+1)} > 1 \]

hence we have:

\[ m_{i1} + ... + m_{ia} + m_{i(a+1)} = 2 \]

\[ m_{i1} + ... + m_{ia} \leq 1 \] (for safe PN) \[ m_{i1} + ... + m_{ia} \leq 1 \]

Then \( P_i P_j P_{a(1)} \) is an over-state of authorized states that is not true, then:

\[ m_{i1} + ... + m_{ia} + m_{i(a+1)} \leq 1 \]

Remark 3. A constraint \( m_1 + m_2 + ... + m_k \leq k \) can be presented by \( (P_1 P_2 ... P_k) \).

Property 3. Let \( M = \{ (P_1 P_2 ... P_k) , ... , (P_1 P_2 ... P_k) \} \) be the subset of constraints verified the authorized states. If the authorized states verify the partial invariant \( m_1 + m_2 + ... + m_r \leq 1 \) the r constraints are equivalent to one constraint as bellow:

\[ (m_1 + m_2 + ... + m_r) + m_1 + ... + m_r \leq k \]

Proof: Necessary condition:

\[ \forall q \in \{1, ..., r \} \quad m_q + m_1 + ... + m_r \leq k \Rightarrow m_1 + ... + m_r \leq k \]

And also from the constraint, we have:

\[ m_1 + m_2 + ... + m_r \leq 1 \]

By adding two constraints, we have:

\[ (m_1 + m_2 + ... + m_r) + m_1 + ... + m_r \leq k + 1 \]

We show that the value \( k+1 \) is not any time accessible. Suppose that \( k+1 \) is accessible. We have:

\[ m_1 + m_2 + ... + m_r \leq k \]

From the r constraints and equation \( m_1 + ... + m_r = k \), we have:

\[ m_1 = m_2 = ... = m_r = 0 \]

Then:

\[ (m_1 + m_2 + ... + m_r) = 0 \]

That is not true.

Sufficient condition:

\[ (m_1 + ... + m_k) + m_1 + ... + m_r \leq k \]

\[ \forall q \in \{1, ..., r \} \quad m_q \geq 0 \Rightarrow m_1 + m_2 + ... + m_r \leq k \]
Generally, by application of these properties, it is possible to simplify the constraints. However, for our example, it is not possible to do more simplification using these properties. Suppose that the sets \( A_1 \) and \( B_1 \) be the sets of authorized and forbidden states, respectively:

\[
A'_1 = \{P_1P_3P_5P_7, P_1P_3P_5P_7, P_1P_4P_5P_8, P_2P_3P_6P_8\}
\]

\[
B'_1 = \{P_1P_4P_5, P_2P_4P_5, P_2P_5P_7, P_4P_5\}
\]

By application of property 1 and 3 for states \( \{P_1P_3P_5P_7, P_1P_3P_5P_7, P_1P_4P_5P_8, P_2P_3P_6P_8\} \), we have: \( m_1 + m_2 + m_4 + m_5 \leq 2 \). For states \( \{P_1P_3P_5P_7, P_1P_4P_5P_8, P_2P_3P_6P_8\} \), the constraint \( m_2 + m_4 \leq 1 \) is not verified, but is it necessary? We show that it is not necessary. When the borne of constraints is more than 1, for having \( m_2 + m_4 + m_5 \leq 2 \), it is not necessary \( m_2 + m_4 \leq 1 \) but also it is necessary that \( m_2 + m_4 + m_5 \leq 2 \) and \( m_2 + m_4 + m_7 \leq 2 \) be true.

The following properties generalizes this idea.

**Property 4** suppose that we have the set of constraints:

\( C = \{(P_1P_3P_5P_7, P_2P_3P_5P_7, \ldots P_n)\} \). Consider \( n \) over-states as follow:

\[
P_1P_3P_5P_7, P_1P_3P_5P_7, P_1P_4P_5P_8, P_2P_3P_6P_8
\]

If none of these states are in the set of over-states of authorized states, then we can reduce these constraints to one constraint as follow:

\[
P_1P_3P_5P_7P_2P_3P_6P_8\text{ that means:}
\]

\[
m_1 + m_2 + m_3 + m_4 + \cdots + m_n \leq n
\]

**Proof:** the proof of this property is clear. Suppose that the inequality \( m_1 + m_2 + m_3 + m_4 + \cdots + m_n \leq n \) is not true then \( m_1 + m_2 + m_3 + \cdots + m_n = n+1 \), that means \((n+1)\) places is marked in the set of \( \mathcal{P} = (P_1, P_2, P_3, \ldots P_n) \) then at least one of the condition in the property is violated. So our supposition is not true.

**Property 5.** Suppose that we have the constraints \( C_1 = (P_1P_3P_5P_7, P_2P_3P_5P_7, \ldots P_n) \) and \( C_2 = (P_{m+1}, P_2P_3P_5P_7, \ldots P_n) \), that verify the authorized states. If all of the over-states content \( n+1 \) places from the sets \( \mathcal{P} = (P_{n+1}, P_2P_3P_5P_7, \ldots P_n) \) are not exist in the sets of over-states of authorized states, the two constraints \( C_1 \) and \( C_2 \) can be replaced by one constraint as follow:

\[
P_1P_3P_5P_7P_2P_3P_6P_8\text{ and }P_{m+1}P_2P_3P_6P_8
\]

**Proof:** the proof of this property is similar to the proof of property 4. Suppose that the inequality \( m_1 + m_2 + m_3 + m_4 + \cdots + m_n = n \) is not true then \( m_1 + m_2 + m_3 + \cdots + m_n = n+1 \), that means \((n+1)\) places is marked in the set of \( \mathcal{P} = (P_1, P_2, P_3, \ldots P_n) \) at least one of the condition in the property is violated. So our supposition is not true.

### 5.1. More simplification in our example by new idea

From section 4.1 we have:

\[
B_3 = \{P_2P_4P_6P_8, P_2P_4P_8, P_2P_4P_{10}, P_2P_6P_8, P_2P_6P_{10}, P_2P_8P_{12}, P_2P_8P_{14}, P_2P_8P_{10}, P_2P_8P_{12}, P_2P_8P_{14}\}
\]

We can select the subset \( C_1 \) that contains two common places and one different place. \( C_1 = (P_2P_4P_6, P_2P_4P_8) \).

The over-state \( P_6P_8 \) is in the set of over-states of authorized states. So it is impossible to use the property 2, but the states \( P_6P_8, P_6P_8 \), are not in the set of over-states of authorized states, then it is possible to use the property 4.

\[
\begin{align*}
C_1 & = \{(P_2P_4P_6, P_2P_4P_8) \} \\
\text{For applying the property 5 on the sets of } C_1 \text{ and } C_2 & \Rightarrow \text{ it is clear that the over-states } P_6P_8, P_6P_8 \text{, are not in the set of over-states of authorized states, then, we arrive to the simplified constraint:} \\
C_2 & = (P_2P_4P_6) \\
\end{align*}
\]

By the same way for the sets \( C_3 \) and \( C_4 \) we can arrive to the simplified constraints as bellow:

\[
\begin{align*}
C_3 & = (P_2P_4P_6, P_2P_4P_8, P_2P_4P_{10}) \Rightarrow \text{ C3 } \in \{(P_2P_4P_6, P_2P_4P_8, P_2P_4P_{10}) \} \\
C_4 & = (P_2P_4P_6, P_2P_4P_8, P_2P_4P_{10}) \Rightarrow \text{ C4 } \in \{(P_2P_4P_6, P_2P_4P_8, P_2P_4P_{10}) \} \\
\end{align*}
\]

So it is obvious that with using these properties the 9 constraints have reduced to one constraint that is good reason for utilization of these properties.

In this example, there is not the final selection, but generally by the method as the same was presented in last section, we can select the final result.

### 5.2. Calculation of control places

To calculate the control places corresponding for each linear constraint, we will use the method developed in Yamalidou et al. (2006). Now we briefly present this method that is based on concept of P-invariant. Suppose that we have the set of constraints as \( L, m_p \leq b \) that \( m_p \) is the marking vector of system, \( L \) is a \( n \times n \) matrix, \( b \) is a \( n \times 1 \) vector, \( n \) is the number of constraints and \( n \) is the number of places. In this method for each constraint, we add a place to the PN model of the system. In Yamalidou et al. (2006), it is proved that this places guarantees that these constraints are respected. Suppose \( W_p \) be the incidence matrix of the system. For each constraint we add a row to \( W_p \) and we show this row as \( W_c \), corresponds to the incidence matrix of the controller. And \( W_c \) is calculated as follows:

\[
W_c = L \times W_p
\]

\( W_c \) is added to \( W_p \) as follow:

\[
W = \begin{bmatrix}
W_p \\
W_c
\end{bmatrix}
\]

If the initial marking of system is \( m_{0in} \), the initial marking for the added places is calculated as follow:
Now we calculate the control places for our example. The simplified constraint was $(P_2 P_4 P_6 P_{10}, 2)$. Then we have:

$L = [0 1 0 1 0 1 0 1 0 1] \Rightarrow W_c = [-1 0 0 -1 0 0 -1 0 0 1 1]$, 

$M_{s0} = 2$

The PN model of the final controller after adding the control place is indicated in fig 3. The control place and corresponding arcs are shown with gray color.

Fig. 3. Controlled PN model

As it is obvious from fig. 3, with adding $P_{c1}$, forbidden states can not be reached.

6. CONCLUSION

In this paper, we have presented a systematic method to reduce the number of linear constraints corresponding to the forbidden states for a safe PN. This is realized by using non-reachable states and by building the constraints using a systematic method. The important concept of over-state has been used; it corresponds to a set of markings which keep the same property (forbidden or authorized). From the forbidden states, the set of over-states is calculated. The utilization of non-reachable markings allows great simplification of the constraints.

In this paper, we have extended the idea presented in Dideban & Alla (2008). We have used the partial invariant for more simplifications. Finally, we have shown that sometimes it is possible to simplify without invariant or partial invariant. By this method we can arrive to very simplified constraints deduced from the forbidden states.
