*Received 3 April 2000*

Since Mellès has shown that  $\lambda\sigma$  (a calculus of explicit substitutions) does not preserve the strong normalization of the  $\beta$ -reduction, it became a challenge to find a calculus satisfying the following properties: step by step simulation of the  $\beta$ -reduction, confluence on terms with metavariables, strong normalization of the calculus of substitutions and preservation of the strong normalization of the  $\lambda$ -calculus. We present here such a calculus. The main novelty of the calculus (given with de Bruijn indices) is the use of *labels* that represent updating functions and correspond to explicit weakening. A typed version is also presented.

## 1. Introduction

Calculi of explicit substitutions are useful tools that fill the gap between the meta operation of substitution appearing in the  $\beta$ -reduction of the  $\lambda$ -calculus and its concrete implementation.

The most natural property such calculi have to satisfy is the simulation of the  $\beta$ -reduction (SIM): every  $\beta$ -reduction can be done in the new calculus and conversely this calculus does not introduce other reductions.

To have a good implementation of the  $\lambda$ -calculus, it is also natural to ask that no infinite reductions are created by the use of explicit substitutions. This is called the preservation of strong normalization (PSN). Melliès gave in (Melliès, 1995) a simply typed term with an infinite reduction in  $\lambda\sigma$ . This counter-example shows that  $\lambda\sigma$  has not PSN.

Another important property is to have the confluence on terms with metavariables (MC): in proof assistants or theorem provers one has to consider proof trees with some unknown subtrees. To represent these proof trees,  $\lambda$ -terms with metavariables (corresponding to unknown parts of the tree) are necessary. The confluence on usual (closed) terms is easy to obtain but MC is much more difficult.

Since Melliès gave his counter-example, many calculi have been proposed but none of them satisfies simultaneously SIM, PSN and MC. Figure 1 gives some of them and their properties.

In order to satisfy both SIM and MC, rules for the interaction between substitutions are necessary. These rules are responsible for the lack of PSN in  $\lambda\sigma$  and  $\lambda s_e$ . In  $\lambda d$  and  $\lambda\sigma_n$ , a weaker notion of composition is used and thus PSN is satisfied, but these rules are not strong enough to get MC.

The  $\lambda s$ -calculus is the most natural calculus of explicit substitutions: it is the  $\lambda$ -calculus (with de Bruijn indices) where the substitution ( $\sigma^i$ ) and the updating ( $\phi_j^k$ ) have been

		SIM	PSN	MC
without interaction	$\lambda\nu$ (Benaissa et al., 1996)	Yes	Yes	No
	$\lambda s$ (Kamareddine and Ríos, 1995b)	Yes	Yes	No
	$\lambda\zeta$ (Muñoz, 1996; Muñoz, 1997)	Big step	Yes	Yes
with interaction	$\lambda\sigma$ (Abadi et al., 1991)	Yes	No	Yes
	$\lambda s_e$ (Kamareddine and Ríos, 1997)	Yes	No	Yes
	$\lambda d$ (Ferreira et al., 1996)	Yes	Yes	No
	$SKInT$ (Goguen and Goubault-Larrecq, 1999)	Yes	Yes	Yes

Fig. 1. Calculi of explicit substitutions and their properties

internalized. The  $\lambda s_e$ -calculus is obtained by adding new rules for the interaction of substitutions. This set of rules is the minimal one to get MC but unfortunately,  $\lambda s_e$  does not satisfy PSN (Guillaume, 1999a).

In the following example, the  $\beta$ -reduction is done in two steps: first, the reduction of the  $\beta$ -redex and the propagation of the substitution and then, the propagation of the updating function. The  $\langle 1 \rangle$  in the middle term means that the free indices in the term below must be increased by 1. This corresponds to the function  $\phi_0^1$  in  $\lambda s_e$ .

**Example 1.1.**

The rules for the propagation of the updating functions are responsible for the lack of PSN in  $\lambda s_e$  (Guillaume, 1999a). The key idea of our calculus is to keep the information about updating in terms rather than to move it down. In others words, we decide that (in the example above) the “right” reduct of the term is the second rather than the third one.

Recently, another solution which relies on a translation of  $\lambda$ -terms into sequent combinators has been proposed (Goguen and Goubault-Larrecq, 1999). Goguen and Goubault introduce a first order calculus (named  $SKIn$ ) on the set of terms defined by:

$$t ::= x \mid I_m \mid K_m(t) \mid S_m(t, t)$$

where  $I_m$ ,  $k_m$  and  $S_m$  are generalizations of the usual combinators  $I$ ,  $K$  and  $S$ . The translation of the  $\lambda$ -term  $t$  in  $SKIn$  is written  $t^*$  and the reverse one  $\llbracket u \rrbracket$  for any  $SKIn$ -term  $u$ . They show that  $t \rightarrow_{\beta} u$  implies  $t^* \rightarrow_{SKIn}^+ u^*$  but conversely, they only have that  $t \rightarrow_{SKIn} u$  implies  $\llbracket t \rrbracket \rightarrow_{\beta_{\eta}}^* \llbracket u \rrbracket$ . Unfortunately, with an example à la Mellies,

they show that *SKIn* is not strongly normalizing in the typed case and thus that it does not have PSN.

To recover the PSN, they define the *SKInT*-calculus on the same syntax but with less permissive rules. This second calculus has the expected properties (including PSN) but the relation with the  $\lambda$ -calculus is more complicated than for *SKIn*. The logic behind *SKInT* is a fragment of the modal logic S4 called *near-intuitionistic logic*. The corresponding notion of “ $\lambda$ -calculus” is a closure calculus (named  $\lambda_{clos}$ ) which is an extension of call-by-value (CBV)  $\lambda$ -calculus. The  $\lambda$ -calculus is translated in *SKInT* in the following way: first, encode the  $\lambda$ -calculus in the CBV  $\lambda$ -calculus (using for example a continuation passing style (CPS) transformation), then use a translation from  $\lambda_{clos}$  to *SKInT*. Denoting by  $L^*(t)$  the translation of the  $\lambda$ -term  $t$  in *SKInT*, they prove:

- if  $t \rightarrow_{\beta} u$  then  $L^*(t) \rightarrow_{SKInT}^* L^*(u)$ ;
- $t$  and  $u$  are convertible if and only if  $L^*(t)$  and  $L^*(u)$  are convertible in *SKInT*.

The paper is organized as follow: we first introduce the  $\lambda_w$ -calculus (section 3) which is the usual  $\lambda$ -calculus (with de Bruijn indices) where terms may contain labels  $\langle k \rangle$ , then we give the  $\lambda_{ws}$ -calculus (section 4) which is obtained from the  $\lambda_w$ -calculus by making the substitutions explicit and by adding rules for interaction between substitutions.

The sections from 5 to 8 are devoted to the proofs of the main properties of the  $\lambda_{ws}$ -calculus. The most innovative section is the last one where the PSN is proved.

*Warning:* This paper is the complete version of the extended abstract presented in WESTAPP’99 (David and Guillaume, 1999). There, the  $\lambda_{ws}$ -calculus was called  $\lambda_l$  ( $l$  for label).

## 2. Preliminaries

We give here some definitions and useful lemmas about rewriting systems. We also recall the rules for the usual  $\beta$ -reduction on  $\lambda$ -terms with de Bruijn indices and the explicit substitution calculus  $\lambda_{se}$ .

### 2.1. Rewriting

**Definition 2.1 (Abstract rewriting systems).** Let  $E$  be a set of terms and  $R$  be a set of rewriting rules. We denote by  $\rightarrow_R$  the binary relation on  $E$  defined by the contextual closure of the set of rules.

We also write  $\rightarrow_R^*$  (resp.  $\rightarrow_R^{\dagger}$ ) for the transitive and reflexive closure, (resp. transitive closure) of  $\rightarrow_R$ .

**Definition 2.2 (Normal form).** We say that  $t \in E$  is an  $R$ -normal form if there are no terms  $u$  such that  $t \rightarrow_R u$ . The set of  $R$ -normal forms is denoted by  $NF(R)$ .

**Definition 2.3 (Normalization).**

- A term  $t \in E$  is strongly normalizable if there is no infinite  $R$ -reduction of  $t$ , i.e. if every sequence  $t \rightarrow_R t_1 \rightarrow_R t_2 \dots$  is finite. The set of  $R$ -strongly normalizable terms is denoted by  $SN(R)$ . If  $SN(R) = E$ , we say that the reduction  $R$  is strongly normalizing.

- A term  $t$  is weakly normalizable if there is a finite reduction  $t \rightarrow_R^* u$  where  $u$  is an  $R$ -normal form. The set of  $R$ -weakly normalizable terms is denoted by  $WN(R)$ . If  $WN(R) = E$ , we say that the reduction  $R$  is weakly normalizing.

**Definition 2.4 (Confluence).**

- A reduction  $\rightarrow_R$  is confluent if, for  $t, u, v \in E$  such that  $t \rightarrow_R^* u$  and  $t \rightarrow_R^* v$  there is  $w$  such that  $u \rightarrow_R^* w$  and  $v \rightarrow_R^* w$ .
- A reduction  $\rightarrow_R$  is locally confluent if, for  $t, u, v \in E$  such that  $t \rightarrow_R u$  and  $t \rightarrow_R v$  there is  $w$  such that  $u \rightarrow_R^* w$  and  $v \rightarrow_R^* w$ .
- A reduction  $\rightarrow_R$  is strongly confluent if, for  $t, u, v \in E$  such that  $t \rightarrow_R u$  and  $t \rightarrow_R v$  there is  $w$  such that  $u \rightarrow_R w$  and  $v \rightarrow_R w$ .

**Remark 2.5.** The reduction  $\rightarrow_R$  is confluent if and only if the reduction  $\rightarrow_R^*$  is strongly confluent.

**Lemma 2.6 (Newman's lemma).** If the reduction  $\rightarrow_R$  is strongly normalizable and locally confluent, then it is confluent.

The following lemmas will be used in section 8. The second one is a particular case of the first one.

**Lemma 2.7 (Projection lemma).** Let  $R, S$  be reductions on  $E$  and  $F$  respectively and  $\succsim$  be a binary relation on  $E \times F$ . Assume that:

- $R = R_1 \cup R_2$ .
- $R_1$  is strongly normalizing.
- If  $t \rightarrow_{R_1} t'$  and  $t \succsim u$  then there is  $u'$  such that  $u \rightarrow_S^* u'$  and  $t' \succsim u'$ .
- If  $t \rightarrow_{R_2} t'$  and  $t \succsim u$  then there is  $u'$  such that  $u \rightarrow_S^+ u'$  and  $t' \succsim u'$ .

Let  $t \in E, u \in F$  with  $t \succsim u$ . If  $u \in SN(S)$  then  $t \in SN(R)$ .

*Proof.* From an infinite  $R$ -reduction of  $t$ , we can construct an infinite  $S$ -reduction of  $u$ :

$$\begin{array}{ccccccc}
 t = t_0 & \xrightarrow{R_1^*} & t'_0 & \xrightarrow{R_2} & t_1 & \xrightarrow{R_1^*} & t'_1 & \longrightarrow & \dots \\
 \Downarrow & & \Downarrow & & \Downarrow & & \Downarrow & & \\
 u = u_0 & \dots\dots\dots & \xrightarrow{S^*} & u'_0 & \dots\dots\dots & \xrightarrow{S^+} & u_1 & \dots\dots\dots & \xrightarrow{S^*} & u'_1 & \dots\dots\dots & \longrightarrow & \dots
 \end{array}$$

□

The next lemma corresponds to the particular case where  $R$  contains the equality (i.e. for all  $t$ , we have  $t \succsim t$ ) and  $S = R_2$ .

**Lemma 2.8 (Simulation lemma).** Let  $R = R_1 \cup R_2$  be a reduction on the set  $E$  and  $\succsim$  be a binary relation on  $E \times E$ . Assume that:

- For all  $t \in E$ , we have  $t \succsim t$ .
- $R_1$  is strongly normalizable.
- If  $t \rightarrow_{R_1} t'$  and  $t \succsim u$  then there is  $u'$  such that  $u \rightarrow_{R_2}^* u'$  and  $t' \succsim u'$ .
- If  $t \rightarrow_{R_2} t'$  and  $t \succsim u$  then there is  $u'$  such that  $u \rightarrow_{R_2}^+ u'$  and  $t' \succsim u'$ .

Then  $SN(R) = SN(R_2)$ .

The lemma 2.10 is an adaptation of a result given in (Klop, 1992). The original result is that a rewriting system which is locally confluent, weakly normalizing and increasing (there is a measure which is strictly increased by reduction) is also strongly normalizing. In lemma 2.10, the measure is only increasing (not strictly) but we have the additional hypothesis that reductions which leave the measure unchanged are strongly normalizing.

**Lemma 2.9.** Let  $R$  be a locally confluent reduction,  $t$  be a normalizable term and  $v$  be a normal form of  $t$ . Assume  $t \notin SN(R)$ . Then, there is a term  $u \notin SN(R)$  such that  $t \xrightarrow{+}_R u$  and  $v$  is a normal form of  $u$ .

*Proof.* Let  $t = t_0 \rightarrow t_1 \rightarrow \dots \rightarrow t_n = v$  a derivation from  $t$  to  $v$ . Let  $i$  be such that  $t_i \notin SN(R)$  and  $t_{i+1} \in SN(R)$  and  $u$  be a term such that  $t_i \rightarrow u$  and  $u \notin SN(R)$ .

Since  $R$  is locally confluent there is a term  $w$  such that  $u \xrightarrow{*} w$  and  $t_{i+1} \xrightarrow{*} w$ . Since  $t_{i+1} \in SN(R)$  and  $R$  is locally confluent,  $t_{i+1}$  has a unique  $R$ -normal form  $v$  and thus  $v$  also is a normal form of  $w$ . Finally, we have  $t \xrightarrow{+} u$  and  $v$  is an  $R$ -normal form of  $u$ .

□

**Lemma 2.10 (Increasing reductions).** Let  $R = R_1 \cup R_2$  and  $|\cdot|$  be a measure such that:

- $R_1$  is strongly normalizing.
- If  $t \xrightarrow{R_1} t'$  then  $|t| = |t'|$ .
- If  $t \xrightarrow{R_2} t'$  then  $|t| < |t'|$ .
- $R$  is weakly normalizing.
- $R$  is locally confluent.

Then  $R$  is strongly normalizing.

*Proof.* Assume there is a term  $t$  which is not  $R$ -strongly normalizable. The weak normalization of the  $R$ -reduction ensures that  $t$  has an  $R$ -normal form  $v$ . By lemma 2.9 we can construct an infinite derivation:  $t = t_0 \xrightarrow{+} t_1 \xrightarrow{+} \dots \xrightarrow{+} t_i \xrightarrow{+} \dots$  such that  $v$  is an  $R$ -normal form of each  $t_i$ . Since  $R_1$  is strongly normalizing, there are infinitely many  $R_2$ -reductions in this derivation. Thus,  $|t_j| > |v|$  for some  $j$ . This gives a contradiction since  $t_j \xrightarrow{*}_R v$  and thus  $|t_j| \leq |v|$ . □

## 2.2. The $\lambda$ -calculus with de Bruijn indices: the $\lambda_{db}$ -calculus

We will use de Bruijn representation of  $\lambda$ -terms where the first index is  $\underline{0}$  and not  $\underline{1}$ . This will simplify notations in the next sections and, this is more natural with respect to the typed calculus. For instance, the  $\lambda$ -term  $\lambda x \lambda y (x y)$  is written  $\lambda \lambda (\underline{1} \underline{0})$ .

Substitutions will be written on the left of the terms (for example  $\{x := u\}t$  means  $t$  where  $x$  is substituted by  $u$ ): this corresponds to the tree representation of terms and we believe this is easier to read.

Terms of the  $\lambda_{db}$ -calculus are defined by:

$$t ::= \underline{n} \mid \lambda t \mid (t t) \quad \text{with } n \in \mathbb{N}$$

The  $\beta$ -reduction is given by the next definition.  $\{i := u\}$  (the substitution) and  $\phi$  (the updating function) are meta functions, i.e. are not in the syntax of the calculus.

**Definition 2.11.** The  $\lambda_{db}$ -calculus is defined by the rule:

$$(\lambda t u) \longrightarrow_{\lambda_{db}} \{0 := u\}t$$

with:

$$\begin{aligned} \{i := u\}\lambda t &= \lambda\{i + 1 := u\}t & \phi_i^j(\lambda t) &= \lambda\phi_{i+1}^j(t) \\ \{i := u\}(t v) &= (\{i := u\}t \{i := u\}v) & \phi_i^j(t u) &= (\phi_i^j(t) \phi_i^j(u)) \\ \{i := u\}\underline{n} &= \begin{cases} \underline{n} & \text{if } n < i \\ \phi_0^i(u) & \text{if } n = i \\ \underline{n-1} & \text{if } n > i \end{cases} & \phi_i^j(\underline{n}) &= \begin{cases} \underline{n} & \text{if } n < i \\ \underline{n+j} & \text{if } n \geq i \end{cases} \end{aligned}$$

It is well known that this reduction is isomorphic to the usual  $\beta$ -reduction on  $\lambda$ -terms modulo  $\alpha$ -equivalence (Kamareddine and Ríos, 1998).

### 2.3. The $\lambda_s$ -calculus and the $\lambda_{s_e}$ -calculus

The  $\lambda_s$ -calculus and the  $\lambda_{s_e}$ -calculus were introduced and studied by Kamareddine and Ros (Kamareddine and Ríos, 1995a; Kamareddine and Ríos, 1997). They both use the same syntax. The  $\lambda_s$ -calculus is obtained naturally from the  $\lambda_{db}$ -calculus by writing explicitly the substitutions and the updating functions.

$$t ::= \underline{n} \mid \lambda t \mid (t t) \mid [i := t]t \mid \langle i, j \rangle t \quad \text{with } n, i, j \in \mathbb{N}$$

**Remark 2.12.** In the papers by Kamareddine and Ros, the first De Bruijn index is  $\underline{1}$  whereas we use  $\underline{0}$ . The term  $[i := u]t$  correspond to the term  $t\sigma^{i+1}u$  in the original syntax and  $\langle i, j \rangle t$  correspond to  $\varphi_{i+1}^j(t)$ .

Rules are translation of the definition 2.11:

$$\begin{array}{llll}
(\beta) & (\lambda t u) & \longrightarrow & [0 := u]t \\
(\sigma\lambda) & [i := u]\lambda t & \longrightarrow & \lambda[i + 1 := u]t \\
(\sigma a) & [i := u](t v) & \longrightarrow & ([i := u]t [i := u]v) \\
(\sigma n_1) & [i := u]\underline{n} & \longrightarrow & \underline{n} & \text{if } n < i \\
(\sigma n_2) & [i := u]\underline{n} & \longrightarrow & \langle 0, i \rangle u & \text{if } n = i \\
(\sigma n_3) & [i := u]\underline{n} & \longrightarrow & \underline{n - 1} & \text{if } n > i \\
(\varphi\lambda) & \langle i, j \rangle \lambda t & \longrightarrow & \lambda \langle i + 1, j \rangle t \\
(\varphi a) & \langle i, j \rangle (t u) & \longrightarrow & (\langle i, j \rangle t \langle i, j \rangle u) \\
(\varphi n_1) & \langle i, j \rangle \underline{n} & \longrightarrow & \underline{n} & \text{if } n < i \\
(\varphi n_2) & \langle i, j \rangle \underline{n} & \longrightarrow & \underline{n + j} & \text{if } n \geq i
\end{array}$$

This calculus lacks only the metaconfluence property. In order to recover this property, the reduction relation is extended to give the  $\lambda s_e$ -calculus. The extra rules are:

$$\begin{array}{llll}
(\sigma\sigma) & [i := u][j := v]t & \longrightarrow & [j := [i - j := u]v][i + 1 := u]t & \text{if } j \leq i \\
(\sigma\varphi_1) & [i := u]\langle j, k \rangle t & \longrightarrow & \langle j, k - 1 \rangle t & \text{if } j \leq i < j + k \\
(\sigma\varphi_2) & [i := u]\langle j, k \rangle t & \longrightarrow & \langle j, k \rangle [i - k := u]t & \text{if } j + k \leq i \\
(\varphi\sigma) & \langle j, k \rangle [i := u]t & \longrightarrow & [i := \langle j - i, k \rangle u]\langle j + 1, k \rangle t & \text{if } i \leq j \\
(\varphi\varphi_1) & \langle i, j \rangle \langle k, l \rangle t & \longrightarrow & \langle k, j + l \rangle t & \text{if } k \leq i \leq k + l \\
(\varphi\varphi_2) & \langle i, j \rangle \langle k, l \rangle t & \longrightarrow & \langle k, l \rangle \langle i - l, j \rangle t & \text{if } k + l < i
\end{array}$$

These extra rules are exactly the ones needed to get MC. The strong normalization of the substitution calculus ( $\lambda s_e$  without the rule  $\beta$ ) is an open question.

The PSN was conjectured but its failure has been shown in (Guillaume, 1999a). At first sight, the  $\sigma\sigma$ -rule seems to be the right rule to have PSN: everything is right with respect to the Melliès counter-example. The problem comes from the rules for the interaction between substitutions and updatings. The following example shows where the problem arises.

**Example 2.13.**

$$[4 := u][7 := v]\langle 3, 4 \rangle t \longrightarrow_{\varphi\sigma_2, \sigma\varphi} [4 := u][3 := \langle 0, 4 \rangle v]\langle 4, 4 \rangle t$$

In the left-hand side, the substitution  $[4 := u]$  should not interact with the substitution  $[7 := v]$  (because  $4 < 7$ , the  $\sigma\sigma$ -rule does not apply). In the right-hand side, after two reduction steps, the two substitutions can now interact and produce a self-embedded term as in the Melliès counter-example. This phenomenon can be used to construct an infinite reduction of a simply typed  $\lambda$ -term. See (Guillaume, 1999a) for details.

### 3. The calculus with explicit weakening: $\lambda_w$

#### 3.1. Terms with labels

We avoid the counter-example to the PSN property of the  $\lambda_{s_e}$ -calculus by adding to the usual syntax a new constructor that we call a *label* and which represents an updating information. The term  $t$  with label  $k$  (denoted by  $\langle k \rangle t$ ) corresponds to the term  $t$  where all free indices have been increased by  $k$  (i.e.  $\phi_0^k(t)$  in  $\lambda_{s_e}$ ).

In the terms we are finally interested in, two successive labels are not allowed. We first define preterms without this restriction.

**Definition 3.1.** We define the set of  $\lambda_w$ -preterms by the following grammar:

$$t ::= \underline{n} \mid \lambda t \mid (t t) \mid \langle k \rangle t \quad \text{with } n, k \in \mathbb{N}$$

The function  $E$  defined below gives the  $\lambda_{db}$ -representation of a  $\lambda$ -term represented by a preterm.

**Definition 3.2.** The function  $E$  is defined from the set of preterms to  $\Lambda_{db}$  by:

- $E(\underline{n}) = \underline{n}$
- $E(\lambda t) = \lambda E(t)$
- $E(t u) = (E(t) E(u))$
- $E(\langle k \rangle t) = \phi_0^k(E(t))$

where  $\phi$  is the function from  $\Lambda_{db}$  to  $\Lambda_{db}$  defined by:

- $\phi_i^j(\lambda t) = \lambda \phi_{i+1}^j(t)$
- $\phi_i^j(t u) = (\phi_i^j(t) \phi_i^j(u))$
- $\phi_i^j(\underline{n}) = \begin{cases} \underline{n} & \text{if } n < i \\ \underline{n+j} & \text{if } n \geq i \end{cases}$

**Definition 3.3.**  $\Lambda_w$  is the set of terms given by the following grammar:

$$\begin{aligned} t &::= u \mid \langle k \rangle u \quad \text{with } k \in \mathbb{N} \\ u &::= \underline{n} \mid \lambda t \mid (t t) \quad \text{with } n \in \mathbb{N} \end{aligned}$$

It is easy to define a reduction to recover a  $\lambda_w$ -term from any  $\lambda_w$ -preterm. Let  $m$  be the reduction rule (called mixing):

$$\langle i \rangle \langle j \rangle t \longrightarrow \langle i+j \rangle t$$

This reduction is clearly confluent and strongly normalizable on the set of preterms. We denote by  $m(t)$  the  $\lambda_w$ -term which is the  $m$ -normal form of the preterm  $t$ .

The following lemma ensures that the  $m$ -reduction does not change the meaning of terms.

**Lemma 3.4.** Let  $t, u$  be  $\lambda_w$ -preterms such that  $t \longrightarrow_m u$ , then  $E(t) = E(u)$ . In particular, for each preterm  $t$ , we have  $E(t) = E(m(t))$ .

*Proof.* By an easy induction on the construction of  $t$ . Use the fact that for any  $\lambda_{db}$ -term  $v$ , we have  $\phi_0^k(\phi_0^l(v)) = \phi_0^{k+l}(v)$ .  $\square$

### 3.2. The $\lambda_w$ -calculus

Let  $t = (\langle k \rangle \lambda u v)$ . Since  $E(t)$  is a redex,  $t$  must also be a redex. We thus need a rule to reduce a redex which contains a label and the substitution must record this label. The substitution  $\{i/u, j\}$  means that the indices  $i$  must be replaced by  $\langle i \rangle u$  and that there was a label  $\langle j \rangle$  in the redex.

Note that, even if  $t$  and  $u$  are terms,  $\{i/u, j\}t$  only is a preterm. This is why, in the next definition, the  $m$ -normal form has to be taken in the  $\beta$ -rules. In the final calculus, the  $m$ -rule will also be an explicit rule.

**Definition 3.5.** The  $\lambda_w$ -calculus is defined on the set  $\Lambda_w$  by the two rules:

$$\begin{aligned} (\beta_1) \quad (\lambda t u) &\longrightarrow m(\{0/u, 0\}t) \\ (\beta_2) \quad (\langle k \rangle \lambda t u) &\longrightarrow m(\{0/u, k\}t) \end{aligned}$$

with:

$$\begin{aligned} - \{i/u, j\} \underline{n} &= \begin{cases} \underline{n} & \text{if } n < i \\ \langle i \rangle u & \text{if } n = i \\ \underline{n + j - 1} & \text{if } n > i \end{cases} \\ - \{i/u, j\} \lambda t &= \lambda(\{i + 1/u, j\}t) \\ - \{i/u, j\}(t v) &= ((\{i/u, j\}t) (\{i/u, j\}v)) \\ - \{i/u, j\}\langle k \rangle t &= \begin{cases} \langle k + j - 1 \rangle t & \text{if } i < k \\ \langle k \rangle (\{i - k/u, j\}t) & \text{if } i \geq k \end{cases} \end{aligned}$$

### 3.3. Simply typed $\lambda_w$ -calculus

As usual, types (denoted by  $A, B, \dots$ ) are constructed with basic types and  $\rightarrow$ . Contexts (denoted by  $\Gamma, \Delta, \dots$ ) are lists of types.  $|\Gamma|$  denotes the length of  $\Gamma$ . The typing rules are given below (where  $|\Gamma| = i$ ).

$$\begin{array}{c} \frac{}{\Gamma, A, \Delta \vdash \underline{i} : A} (ax) \qquad \frac{A, \Gamma \vdash t : B}{\Gamma \vdash \lambda t : A \rightarrow B} (\rightarrow_i) \\ \\ \frac{\Gamma \vdash t : A \rightarrow B \quad \Gamma \vdash u : A}{\Gamma \vdash (t u) : B} (\rightarrow_e) \qquad \frac{\Delta \vdash t : A}{\Gamma, \Delta \vdash \langle i \rangle t : A} (weak) \end{array}$$

The first three rules are the usual ones of the  $\lambda_{db}$ -calculus. The last rule introduces labels. A label corresponds to a weakening in the proof tree associated with the term. This is the motivation of the subscript “ $w$ ” in the name of the calculus.

The proof of subject reduction is straightforward.

**Theorem 3.6 (Subject reduction).** Let  $t, u \in \Lambda_w$ . Assume  $t \longrightarrow_{\lambda_w}^* u$  and  $\Gamma \vdash t : A$ . Then  $\Gamma \vdash u : A$ .

It is easy to check that if  $\Gamma \vdash t : A$ , then  $\Gamma \vdash E(t) : A$ . The following result follows then immediately from theorem 3.15 below.

**Theorem 3.7 (Strong normalization).** Every typed  $\lambda_w$ -terms is strongly normalizable.

### 3.4. $\lambda_w$ versus $\lambda_{db}$

In this subsection we show that the  $\lambda_w$ -calculus corresponds to the usual notion of  $\beta$ -reduction. We need some easy lemmas. Their detailed proof can be found in (Guillaume, 1999b).

**Remark 3.8.** Let  $t \in \Lambda_{db}$  and  $i \in \mathbb{N}$ . Then  $\phi_i^0(t) = t$ .

**Lemma 3.9.** Let  $t \in \Lambda_{db}$ . Then

- 1 If  $k \leq i \leq k + l$  then  $\phi_i^j(\phi_k^l(t)) = \phi_k^{j+l}(t)$ .
- 2 If  $i > k + l$  then  $\phi_i^j(\phi_k^l(t)) = \phi_k^l(\phi_{i-l}^j(t))$ .

**Lemma 3.10.** Let  $t, u \in \Lambda_{db}$  and  $i \leq k < i + j$ . Then  $\{k := u\}\phi_i^j(t) = \phi_i^{j-1}(t)$ .

**Lemma 3.11.** Let  $t, u \in \Lambda_{db}$ .

- 1 If  $i \geq k$  then  $\phi_i^j(\{k := u\}t) = \{k := \phi_{i-k}^j(u)\}\phi_{i+1}^j(t)$ .
- 2 If  $i \leq k$  then  $\phi_i^j(\{k := u\}t) = \{k + j := u\}\phi_i^j(t)$ .

**Lemma 3.12.** Let  $t, u \in \Lambda_{db}$  be such that  $t \rightarrow_{\lambda_{db}} u$ . Then  $\phi_i^j(t) \rightarrow_{\lambda_{db}} \phi_i^j(u)$ .

**Lemma 3.13.** Let  $t, u' \in \Lambda_{db}$  be such that  $\phi_i^j(t) \rightarrow_{\lambda_{db}} u'$ . Then there is a term  $u \in \Lambda_{db}$  such that  $t \rightarrow_{\lambda_{db}} u$  and  $\phi_i^j(u) = u'$ .

#### 3.4.1. The $\lambda_{db}$ -calculus simulates the $\lambda_w$ -calculus

The following lemma translates a  $\lambda_w$ -term with substitution into a  $\lambda_{db}$ -term with substitution.

**Lemma 3.14.** Let  $t, u$  be  $\lambda_w$ -preterms. Then  $E(\{i/u, j\}t) = \{i := E(u)\}\phi_{i+1}^j(E(t))$ .

*Proof.* By induction on  $t$ . If  $t = \lambda v$  or  $t = (v w)$ , the result is trivial.

— If  $t = \underline{n}$  and  $n < i$  then  $E(\{i/u, j\}\underline{n}) = \underline{n} = \{i := E(u)\}\phi_{i+1}^j(E(\underline{n}))$ .

— If  $t = \underline{i}$  then  $E(\{i/u, j\}\underline{i}) = E(\langle i \rangle u) = \phi_0^i(E(u))$ . We have also  $\phi_{i+1}^j(E(\underline{i})) = \underline{i}$  and so  $\{i := E(u)\}\phi_{i+1}^j(E(\underline{i})) = \phi_0^i(E(u))$ .

— If  $t = \underline{n}$  and  $n > i$  then  $E(\{i/u, j\}\underline{n}) = \underline{n + j - 1} = \{i := E(u)\}\phi_{i+1}^j(E(\underline{n}))$ .

— If  $t = \langle k \rangle v$  and  $i \geq k$ , then

$$\begin{aligned} E(\{i/u, j\}\langle k \rangle v) &= E(\langle k \rangle \{i - k/u, j\}v) \\ &= \phi_0^k(E(\{i - k/u, j\}v)) \\ &= \phi_0^k(\{i - k := E(u)\}\phi_{i-k+1}^j(E(v))) \quad \text{induction hypothesis} \\ &= \{i := E(u)\}\phi_0^k(\phi_{i-k+1}^j(E(v))) \quad \text{lemma 3.11(2)} \end{aligned}$$

$$\begin{aligned} \{i := E(u)\}\phi_{i+1}^j(E(\langle k \rangle t)) &= \{i := E(u)\}\phi_{i+1}^j(\phi_0^k(E(v))) \\ &= \{i := E(u)\}\phi_0^k(\phi_{i-k+1}^j(E(v))) \quad \text{lemma 3.9(2)} \end{aligned}$$

— If  $t = \langle k \rangle v$  and  $i < k$ , then

$$\begin{aligned}
\{i := E(u)\} \phi_{i+1}^j(E(\langle k \rangle v)) &= \{i := E(u)\} \phi_{i+1}^j(\phi_0^k(E(v))) \\
&= \{i := E(u)\} \phi_0^{j+k}(E(v)) && \text{lemma 3.9(1)} \\
&= \phi_0^{j+k-1}(E(v)) && \text{lemma 3.10} \\
E(\{i/u, j\} \langle k \rangle v) &= E(\langle j+k-1 \rangle v) \\
&= \phi_0^{j+k-1}(E(v))
\end{aligned}$$

□

The following result shows that the  $\lambda_w$ -reduction corresponds to the usual  $\lambda_{db}$ -reduction.

**Theorem 3.15.** Let  $t, u \in \Lambda_w$ . If  $t \rightarrow_{\lambda_w} u$ , then  $E(t) \rightarrow_{\lambda_{db}} E(u)$ .

*Proof.* By induction on  $t$ .

- If  $t = \lambda v$  and  $u = \lambda v'$ , or  $t = (v w)$  and  $u = (v' w)$ , or  $t = (w v)$  and  $u = (w v')$  with  $v \rightarrow_{\lambda_w} v'$ , we use the induction hypothesis.
- If  $t = \langle k \rangle v$  and  $u = \langle k \rangle v'$  with  $v \rightarrow_{\lambda_w} v'$ , then by induction hypothesis  $E(v) \rightarrow_{\lambda_{db}} E(v')$  and, using lemma 3.12,  $E(t) = \phi_0^k(E(v)) \rightarrow_{\lambda_{db}} \phi_0^k(E(v')) = E(u)$ .
- If  $t = (\lambda v w)$  and  $u = m(\{0/w, 0\}v)$  then  $E(t) = (\lambda E(v)E(w))$  and  $E(t) \rightarrow_{\lambda_{db}} \{0 := E(w)\}E(v)$ .

$$\begin{aligned}
E(u) &= E(m(\{0/w, 0\}v)) \\
&= E(\{0/w, 0\}v) && \text{lemma 3.4} \\
&= \{0 := E(w)\} \phi_1^0(E(v)) && \text{lemma 3.14} \\
&= \{0 := E(w)\}E(v) && \text{remark 3.8}
\end{aligned}$$

Finally,  $E(t) \rightarrow_{\lambda_{db}} E(u)$ .

- If  $t = (\langle k \rangle \lambda v w)$  and  $u = m(\{0/w, k\}v)$  then  $E(t) = (\lambda \phi_1^k(E(v))E(w)) \rightarrow_{\lambda_{db}} \{0 := E(w)\} \phi_1^k(E(v))$ .

$$\begin{aligned}
E(u) &= E(m(\{0/w, k\}v)) \\
&= E(\{0/w, k\}v) && \text{lemma 3.4} \\
&= \{0 := E(w)\} \phi_1^k(E(v)) && \text{lemma 3.14}
\end{aligned}$$

Finally,  $E(t) \rightarrow_{\lambda_{db}} E(u)$ .

□

### 3.4.2. The $\lambda_w$ -calculus simulates the $\lambda_{db}$ -calculus

Conversely, we show that, if  $t$  is a  $\lambda_w$ -term such that  $E(t)$  has a  $\beta$ -redex, then the reduction of this redex can always be simulated in  $\lambda_w$ .

**Theorem 3.16.** Let  $t \in \Lambda_w$  and  $u' \in \Lambda_{db}$  be such that  $E(t) \rightarrow_{\lambda_{db}} u'$ . Then, there is a term  $u \in \Lambda_w$  such that  $t \rightarrow_{\lambda_w} u$  and  $E(u) = u'$ .

*Proof.* By induction on  $t$ . The non trivial cases are the following:

- If  $t = \langle k \rangle v$  then  $E(t) = \phi_0^k(E(v))$ . Since  $E(t) \rightarrow_{\lambda_{db}} u'$ , lemma 3.13 gives a term  $w'$  such that  $E(v) \rightarrow_{\lambda_{db}} w'$  and  $\phi_0^k(w') = u'$ . By the induction hypothesis on  $v$ , we get a term  $w$  such that  $v \rightarrow_{\lambda_w} w$  and  $E(w) = w'$ . Let  $u = \langle k \rangle w$ , then  $t \rightarrow_{\lambda_w} u$  and  $E(u) = \phi_0^k(E(w)) = \phi_0^k(w') = u'$ .
- If  $t = (\lambda v w)$  and  $u' = \{0 := E(w)\}E(v)$  then let  $u = \{0/w, 0\}v$ , we get  $t \rightarrow_{\lambda_w} u$  and  $E(u) = \{0 := E(w)\} \phi_1^0(E(v))$  (lemma 3.14), and finally  $E(u) = u'$  (lemma 3.9(1)).

term	$\lambda_{db}$ -calculus	$\lambda_w$ -calculus
$(inf\ 16\ 20)$	1.441.824 steps 10.5 seconds	101.761 steps 0.9 seconds
$((30\ pred)\ 30)$	607.840 steps 5.6 seconds	38.420 steps 1.4 seconds
$(mult\ 100\ 200)$	142.026 steps 1.7 seconds	80.718 steps 1.6 seconds

Fig. 2. Comparison between the  $\lambda_{db}$ -calculus and the  $\lambda_w$ -calculus

— If  $t = (\langle k \rangle \lambda v w)$  and  $u' = \{0 := E(w)\}\phi_1^k(E(v))$  then let  $u = \{0/w, k\}v$ , we get  $t \rightarrow_{\lambda_w} u$  and  $E(u) = \{0 := E(w)\}\phi_1^k(E(v))$  (lemma 3.14), and so  $E(u) = u'$ .

□

### 3.5. Conclusion: $\lambda_w$ versus $\lambda_{db}$

In our final calculus (the  $\lambda_{ws}$ -calculus defined below), the normal forms of the calculus of substitution are terms of  $\Lambda_w$  and not the usual terms of  $\lambda_{db}$ . We actually think that this gives a better representation of  $\lambda$ -terms.

- The fact that, with labels, a  $\lambda$ -term is not uniquely represented is not a drawback since labels are intrinsic: a term can be put in any context (whatever its labeling is). Therefore in an implementation, the function  $E$  (cf. definition 3.2) would be useless. Moreover, if necessary, the algorithm to check whether two terms represent the same  $\lambda$ -term is clearly linear in the size of the terms. Also note that it does not cost more work to translate a labeled term into a term with variables than to translate a usual de Bruijn term.
- A label in a typed term corresponds to a weakening in the associated proof. In the normalization of a proof, it is natural to move cuts up to the axioms i.e. to propagate substitutions in terms but there is no reason to move weakenings up to the axioms i.e. to propagate labels in terms.
- We hope that labels will give more efficient implementations. Compared with implementations in the representation of de Bruijn, there are no steps of propagation of lifts and many steps of propagation of substitutions are avoided since substitutions are erased earlier when they are useless. A very small implementation of the de Bruijn calculus and the labeled calculus gives an idea of the difference between these two presentations.

Figure 2 gives the number of elementary reduction steps and the time of the reduction to normal form in both systems. These tests were made on a PC-133Mhz with Objective Caml. The integers are the Church numerals. The *inf* function of the first example is an efficient one given in (David, 1994).

Fig. 3. Rules of the  $\lambda_{ws}$ -calculus

#### 4. The $\lambda_{ws}$ -calculus

##### 4.1. Syntax and reduction rules for the $\lambda_{ws}$ -calculus

In this section, we give our new calculus. The syntax is obtained from the syntax of the  $\lambda_w$ -calculus (definition 3.5) by adding a constructor for substitutions. This definition is similar to the definition of the  $\lambda_{se}$ -calculus from the  $\lambda_{db}$ -calculus.

The set  $\Lambda_{ws}$  of terms of the  $\lambda_{ws}$ -calculus is defined by:

$$t ::= \underline{n} \mid \lambda t \mid (t t) \mid \langle k \rangle t \mid [i/t, j]t \quad \text{with } n, i, j, k \in \mathbb{N}$$

Note that, as for the  $\lambda_w$ -calculus, two natural numbers are needed in each substitution: the second one keeps track of labels from redexes of the form  $(\langle k \rangle \lambda t u)$ . Also note that there is no restriction on nested labels:  $\langle k \rangle \langle l \rangle t$  is a valid term of the  $\lambda_{ws}$ -calculus.

The set of rules is given in figure 3. The first two rules deal with  $\beta$ -redexes (with or without labels). The seven next rules come from the definition of the “implicit” substitution (definition 3.5). The composition rules  $c_1$  and  $c_2$  are needed for the confluence: they appear naturally to close the critical pairs  $a/b_1$  and  $a/b_2$  on the terms  $[i/v, j](\lambda t u)$  and  $[i/v, j](\langle k \rangle \lambda t u)$ . Finally, the mixing rule  $m$  deals with nested labels. It has to be made explicit for the simulation of the  $\beta$ -reduction.

**Example 4.1.** The following example shows the use of the rule  $e_1$ . It erases a substitution when a label ensures that this substitution is useless in the term below.

In the last step, the substitution  $[0/v', 0]$  is erased in one step, independently of the complexity of  $u$ .

**Example 4.2.** The rule  $c_2$  looks like the  $\sigma\sigma$ -rule of the  $\lambda_{s_e}$ -calculus. The rule  $c_1$  is less common. This rule can be understood as the simultaneous use of  $c_2$  and  $e_1$ :

In the last but one term, the substitution  $[0/v', 0]$  could be propagated in  $w'$  and  $u$ , but the index 1 in the second substitution ensures that  $[0/v', 0]$  is useless in  $u$ .

**Notation 4.3.** In the following,  $b$  will denote the reduction  $b_1 \cup b_2$ . In the same way, we define  $e = e_1 \cup e_2$ ,  $n = n_1 \cup n_2 \cup n_3$  and  $c = c_1 \cup c_2$ .

**Definition 4.4.** We define two sub-calculus on the set  $\Lambda_{ws}$  of terms:

- The  $ws$ -calculus is the  $\lambda_{ws}$ -calculus without the rules  $b_1$  and  $b_2$ , i.e. the rules  $l$ ,  $a$ ,  $e$ ,  $n$ ,  $c$  and  $m$ .
- The  $p$ -calculus is the calculus of propagation of the substitutions i.e. the  $ws$ -calculus without the rule  $m$ , i.e. the rules  $l$ ,  $a$ ,  $e$ ,  $n$  and  $c$ .

The  $ws$ -calculus allows the propagation of the substitutions and the contraction of successive labels. The  $p$ -calculus allows only the propagation of substitutions. The  $p$ -calculus is introduced for technical reasons: in the proof of PSN, working on  $p$ -normal forms rather than on  $ws$ -normal forms gives a shorter proof. The  $p$ -calculus is also used in the proof of the strong normalization of the  $ws$ -calculus.

**Remark 4.5.** For any  $t \in \Lambda_{ws}$ , we have  $ws(t) = m(p(t))$ , i.e. we can always postpone the mixing rule.

The complexity of a term is defined as usual as the number of constructors of the term:

**Definition 4.6.** The *complexity* of  $t \in \Lambda_{ws}$  (denoted by  $\text{cxt}_y(t)$ ) is defined by:

- $\text{cxt}_y(\underline{n}) = 1$
- $\text{cxt}_y(\lambda u) = 1 + \text{cxt}_y(u)$
- $\text{cxt}_y((u v)) = 1 + \text{cxt}_y(u) + \text{cxt}_y(v)$
- $\text{cxt}_y(\langle k \rangle u) = 1 + \text{cxt}_y(u)$

$$\text{— cxt}_y([i/u, j]v) = 1 + \text{cxt}_y(u) + \text{cxt}_y(v)$$

#### 4.2. Typing rules for the $\lambda_{ws}$ -calculus

As usual, types (denoted by  $A, B, \dots$ ) are constructed with basic types and  $\rightarrow$ . Contexts (denoted by  $\Gamma, \Delta, \dots$ ) are lists of types.  $|\Gamma|$  denotes the length of  $\Gamma$ .

The typing rules are the following (where  $|\Gamma| = i$  and  $|\Delta| = j$ ):

$$\begin{array}{c} \frac{}{\Gamma, A, \Delta \vdash \underline{i} : A} \text{ (ax)} \qquad \frac{A, \Gamma \vdash t : B}{\Gamma \vdash \lambda t : A \rightarrow B} \text{ (}\rightarrow_i\text{)} \\ \\ \frac{\Gamma \vdash t : A \rightarrow B \quad \Gamma \vdash u : A}{\Gamma \vdash (t u) : B} \text{ (}\rightarrow_\epsilon\text{)} \qquad \frac{\Delta \vdash t : A}{\Gamma, \Delta \vdash \langle i \rangle t : A} \text{ (weak)} \\ \\ \frac{\Delta, \Pi \vdash u : A \quad \Gamma, A, \Pi \vdash t : B}{\Gamma, \Delta, \Pi \vdash [i/u, j]t : B} \text{ (cut)} \end{array}$$

We add the *cut* rule to the typing system of subsection 3.3. This rule is twofold : a (usual) cut and a weakening ( $\Delta$  is added to the hypotheses for  $t$ ). Intuitively, the context used to type  $[i/u, j]t$  can be divided into three parts: the first one ( $\Gamma$ , of length  $i$ ) is specific to  $t$ , the next one ( $\Delta$ , of length  $j$ ) is specific to  $u$  and the remaining one ( $\Pi$ ) is common to  $t$  and  $u$ .

It is easy to check that the reduction rules of the  $\lambda_{ws}$ -calculus correspond naturally to the cut elimination process of the proof tree.

**Theorem 4.7 (Subject reduction).** Let  $t, u \in \Lambda_{ws}$ . If  $t \rightarrow_{\lambda_{ws}} u$  and  $\Gamma \vdash t : A$ , then  $\Gamma \vdash u : A$ .

*Proof.* By induction on  $t$ . We may assume that the reduction is at the root. Just check, for each rule, that the reduct can be typed, with the same type and the same hypothesis, as the redex.  $\square$

The rest of the paper is devoted to the untyped  $\lambda_{s_e}$ -calculus. We give here the normalization property of the typed calculus.

**Theorem 4.8.** Every typed  $\lambda_{ws}$ -term is weakly normalizable.

*Proof.* Let  $t \in \Lambda_{ws}$  be typable. Theorem 4.7 ensures that  $ws(t)$  (which exists by sections 5 and 6) is typable. The strong normalization of the typed  $\lambda$ -calculus and the preservation of the strong normalization of the  $\lambda_{ws}$ -calculus (section 8) ensure that  $ws(t)$  is strongly normalizable for the  $\lambda_{ws}$ -calculus. Finally,  $t$  is weakly normalizable.  $\square$

It should be possible to prove the strong normalization of the typed calculus by the same kind of technique as in the proof of PSN. This result has been proved recently (Di Cosmo et al., 2000) by using a translation into proof nets, a technique introduced in (Di Cosmo and Kesner, 1997).

4.3. Link with the  $\lambda_{s_e}$ -calculus

Every  $\lambda_{ws}$ -term  $t$  can be translated in a  $\lambda_{s_e}$ -term (denoted by  $t^\sharp$ ) in the following way. Note that there is no translation in the other way.

- $n^\sharp = n$
- $(\lambda t)^\sharp = \lambda t^\sharp$
- $(t u)^\sharp = (t^\sharp u^\sharp)$
- $(\langle k \rangle t)^\sharp = \langle 0, k \rangle t^\sharp$
- $[i/u, j]t = [i := u^\sharp] \langle i + 1, j \rangle t^\sharp$

The  $\lambda_{ws}$ -calculus can be seen as a part of the  $\lambda_{s_e}$ -calculus where some reductions are forbidden. Intuitively, in  $\lambda_{ws}$ , an updating  $\langle i, j \rangle$  may not move down, except if it appears at the root of the function part of a redex. In this case, the updating may cross the  $\lambda$  but the redex has to be contracted immediately after and this new updating must be linked to the substitution coming from the redex (i.e. they cannot move independently). The relation between both calculi is the following. If  $t \rightarrow_{\lambda_{ws}} u$  then  $t^\sharp \rightarrow_{\lambda_{s_e}}^+ u^\sharp$  and one step of  $\lambda_{ws}$ -reduction can be simulated by a fixed number (from 1 to 4, depending of the rule) of  $\lambda_{s_e}$ -reduction.

## 5. Strong normalization of the calculus of substitutions

In this section, we prove that the  $ws$ -calculus is strongly normalizing. This proof is inspired by the one Zantema gave for the strong normalization of the  $\sigma\sigma$ -rule of the  $\lambda_{s_e}$ -calculus (Zantema, 1998).

We first show, using the simulation lemma (lemma 2.8) that  $SN(ws) = SN(p_2)$  where the  $p_2$ -calculus is the calculus defined by the set of rules that increase (not strictly) the complexity i.e. the rules  $l$ ,  $a$ ,  $e_2$  and  $c$  (subsection 5.2). Then, using the increasing reductions lemma (lemma 2.10), we prove that the  $p_2$ -calculus is strongly normalizing (subsection 5.3). We finally get the theorem:

**Theorem 5.1.** The  $ws$ -calculus is strongly normalizing.

The complete proofs of the lemmas 5.6, 5.7 and of the propositions 5.9, 5.10 and 5.11 can be found in (Guillaume, 1999b).

## 5.1. The substitutive contexts

In the rest of this paper, the notion of “normal form” of a sequence of substitutions is useful. We call such a sequence *substitutive context*.

**Notation 5.2.**  $\overline{\mathbb{N}}$  denotes the set  $\mathbb{N} \cup \{-\infty, \infty\}$  with its natural ordering extended in such a way that  $-\infty$  is the smallest element and  $\infty$  is the greatest one. The addition is extended by  $i + \infty = \infty$  and  $i - \infty = -\infty$  for  $i \in \mathbb{N}$  ( $\infty - \infty$  is not defined).

We use the notation  $*$  to represent a term about which nothing has to be known. The contexts have only one hole (denoted by  $\{\cdot\}$ ).  $C\{\cdot\}$  denotes the context  $C$  in which the hole has been replaced by  $t$ .

**Definition 5.3.** A *substitutive context* is a context:

$$S = [i_1/*, j_1] \dots [i_n/*, j_n] \{\cdot\} \text{ with } n \geq 0 \text{ and } i_1 < \dots < i_n.$$

We define:

— The *initial index*  $i(S) \in \overline{\mathbb{N}}$  of  $S$ :

$$i(S) = \begin{cases} \infty & \text{if } n = 0 \\ i_1 & \text{if } n > 0 \end{cases}$$

— The *final index*  $f(S) \in \overline{\mathbb{N}}$  of  $S$ :

$$f(S) = \begin{cases} -\infty & \text{if } n = 0 \\ i_n & \text{if } n > 0 \end{cases}$$

— The *height*  $h(S) \in \mathbb{N}$  of  $S$ :

$$h(S) = n$$

— The *shift*  $d(S) \in \mathbb{Z}$  of  $S$ :

$$d(S) = \left( \sum_{k=1}^n j_k \right) - n$$

It is important to note that (for technical reasons) we allow a substitutive context to be empty. When there is no ambiguity, we extend the usual notion of reduction on the terms to reduction on contexts.

**Notation 5.4.** If  $S$  is the substitutive context  $[i_1/*, j_1] \dots [i_n/*, j_n]$  we will denote by:

—  $[i/u, j]S$  the substitutive context  $[i/u, j][i_1/*, j_1] \dots [i_n/*, j_n] \{\cdot\}$  if  $i < i(S)$ .

—  $S[i/u, j]$  the substitutive context  $[i_1/*, j_1] \dots [i_n/*, j_n][i/u, j] \{\cdot\}$  if  $i > f(S)$ .

**Remark 5.5.** Let  $S$  be a substitutive context such that  $h(s) > 0$ , then  $f(S) \geq i(S)$ . A trivial induction on  $h(S)$  show that if  $h(s) > 0$  then  $i(S) \leq f(S) - h(S) + 1$ .

The next two lemmas give the result of the “composition” of a substitution with a substitutive context. There are two cases: either the new substitution can “go through” the context (lemma 5.6), or the substitution is “integrated” in the context (lemma 5.7). These two cases are not disjoint: when the substitution goes through the context, we can choose to either integrate it at the end of the context (lemma 5.7) or keep it separated (lemma 5.6).

**Lemma 5.6.** Let  $S$  be a substitutive context, and  $[i/u, j]$  be a substitution such that  $i > d(S) + f(S)$ . Then, there is a substitutive context  $S'$  such that:  $[i/u, j]S \xrightarrow{*}_c S'[i - d(S)/u, j]$ ,  $d(S') = d(S)$  and  $f(S') = f(S)$ .

*Proof.* The proof is by induction on  $h(S)$ : we show that there is a substitutive context  $S'$  such that  $[i/u, j]S \xrightarrow{*}_c S'[i - d(S)/u, j]$ ,  $d(S') = d(S)$ ,  $f(S') = f(S)$  and  $i(S') = i(S)$ .  $\square$

**Lemma 5.7.** Let  $S$  be a substitutive context, and  $[i/u, j]$  a substitution. Then there is a substitutive context  $S'$  such that  $[i/u, j]S \xrightarrow{*}_c S'$ ,  $d(S') = d(S) + j - 1$  and

$$\begin{cases} f(S') = f(S) & \text{if } i \leq d(S) + f(S) \\ f(S') = i - d(S) & \text{if } i > d(S) + f(S) \end{cases}$$

*Proof.* The case  $i > d(S) + f(S)$  is a reformulation of the previous lemma. Indeed, there is a substitutive context  $S''$  such that  $[i/u, j]S \rightarrow_c^* S''[i - d(S)/u, j]$ . Let  $S' = S''[i - d(S)/u, j]$ , we verify that  $S'$  is a substitutive context because  $f(S') = f(S) < i - d(S)$ .

For the second point, remark that  $i \leq d(S) + f(S)$  only if  $h(S) > 0$ . We then use an induction on  $h(S)$  and show that there is a substitutive context  $S'$  such that  $[i/u, j]S \rightarrow_c^* S'$ ,  $d(S') = d(S) + j - 1$ ,  $f(S') = f(S)$  and  $i(S') = \min(i, i(S))$ . □

The following lemma shows how we can erase the context when all the substitutions are useless. This also shows that  $d(S)$  really is a shift.

**Lemma 5.8.** Let  $S$  be a substitutive context. If  $f(s) < k$ , then  $S\{\langle k \rangle t\} \rightarrow_{e_1}^* \langle k + d(S) \rangle t$ .

*Proof.* By induction on  $h(S)$ . The case  $h(S) = 0$  is trivial. If  $h(S) > 0$ , then  $S = S'[i/u, j]$  with  $i < k$  and  $d(S) = d(S') + j - 1$  so

$$S\{\langle k \rangle t\} \rightarrow_{e_1} S'\{\langle k + j - 1 \rangle t\}$$

and we can use the induction hypothesis (because  $f(S') < i \leq k - 1$  and  $f(S') < k + j - 1$ ), we have

$$S'\{\langle k + j - 1 \rangle t\} \rightarrow_{e_1}^* \langle k + j - 1 + d(S') \rangle t = \langle k + d(S) \rangle t.$$

□

## 5.2. Simulation of the $ws$ -calculus in the $p_2$ -calculus

In order to prove that  $SN(ws) = SN(p_2)$ , we use intermediate reductions:

- The  $ws$ -calculus is defined by the rules  $l$ ,  $a$ ,  $e$ ,  $n$ ,  $c$  and  $m$ .
- The  $p$ -calculus (propagation) is defined by the rules  $l$ ,  $a$ ,  $e$ ,  $n$  and  $c$ .
- The  $p_1$ -calculus is defined by the rules  $l$ ,  $a$ ,  $e_2$ ,  $n$  and  $c$ .
- The  $p_2$ -calculus (rules which increase (not strictly) the complexity) is defined by the rules  $l$ ,  $a$ ,  $e_2$  and  $c$ .

The proof is divided in three steps:  $SN(ws) = SN(p)$ ,  $SN(p) = SN(p_1)$  and  $SN(p_1) = SN(p_2)$ .

**Proposition 5.9.**  $SN(ws) = SN(p)$ .

*Proof.*  $ws = p \cup m$ . We use the simulation lemma (lemma 2.8) with  $R_1 = m$ ,  $R_2 = p$  and the relation  $\succ$  on  $\Lambda_{ws} \times \Lambda_{ws}$  defined by:

- $\underline{k} \succ \underline{k}$
- $\lambda t \succ \lambda t'$  iff  $t \succ t'$
- $(tu) \succ (t'u')$  iff  $t \succ t'$  and  $u \succ u'$
- $\langle k \rangle t \succ \langle k_1 \rangle \dots \langle k_n \rangle t'$  iff  $t \succ t'$ ,  $n \geq 1$  and  $k = k_1 + \dots + k_n$
- $[i/u, j]t \succ [i/u', j]t'$  iff  $t \succ t'$  and  $u \succ u'$ .

□

**Proposition 5.10.**  $SN(p) = SN(p_1)$ .

*Proof.*  $p = p_1 \cup e_1$ . We use lemma 2.8 with  $R_1 = e_1$ ,  $R_2 = p_1$ , and the relation  $\succcurlyeq$  defined by:

- $\underline{k} \succcurlyeq \underline{k}$
- $\lambda t \succcurlyeq \lambda t'$  iff  $t \succcurlyeq t'$
- $(tu) \succcurlyeq (t'u')$  iff  $t \succcurlyeq t'$  and  $u \succcurlyeq u'$
- $\langle k \rangle t \succcurlyeq S \llbracket \langle k' \rangle t' \rrbracket$  with  $t \succcurlyeq t'$  and  $S$  is a substitutive context such that  $f(S) < k'$  and  $k = k' + d(S)$
- $[i/u, j]t \succcurlyeq [i/u', j]t'$  iff  $t \succcurlyeq t'$  and  $u \succcurlyeq u'$ .

□

**Proposition 5.11.**  $SN(p_1) = SN(p_2)$ .

*Proof.*  $p_1 = p_2 \cup n$ . We use lemma 2.8 with  $R_1 = n$ ,  $R_2 = p_2$  and the relation  $\succcurlyeq$  defined by:

- $\underline{k} \succcurlyeq t$  for all  $t$
- $\lambda t \succcurlyeq \lambda t'$  iff  $t \succcurlyeq t'$
- $(tu) \succcurlyeq (t'u')$  iff  $t \succcurlyeq t'$  and  $u \succcurlyeq u'$
- $\langle k \rangle t \succcurlyeq v$  iff  $v$  is of one of the following form:
  - $v = \langle k \rangle t'$  and  $t \succcurlyeq t'$
  - $v = S \llbracket [k'/t', j]w \rrbracket$  with  $f(S) < k'$ ,  $k = k' + d(S)$  and  $t \succcurlyeq t'$
- $[i/u, j]t \succcurlyeq [i/u', j]t'$  iff  $t \succcurlyeq t'$  and  $u \succcurlyeq u'$ .

□

### 5.3. Strong normalization of the $p_2$ -calculus

We prove the strong normalization of the  $p_2$ -calculus by using lemma 2.10 where the measure is the complexity and

- $R_1$  = the rules  $l$ ,  $c_1$  and  $e_2$  (the complexity is left unchanged by these rules).
- $R_2$  = the rules  $a$  and  $c_2$  (these rules increase the complexity).

We have to check:

- The reduction  $R_1$  is strongly normalizable (proposition 5.12).
- The reduction  $p_2$  is locally confluent (this is done by analyzing critical pairs).
- The reduction  $p_2$  is weakly normalizing (proposition 5.15).

#### 5.3.1. Strong normalization of the rules that leave complexity unchanged

We use a measure which decreases by  $R_1$ -reduction. This measure is the sum of the complexities of the subterms which are below each substitution of the term.

**Proposition 5.12.** The  $R_1$ -reduction is strongly normalizing.

*Proof.* The measure  $\|\cdot\|$  defined below strictly decreases by  $l$ ,  $c_1$  and  $e_2$ -reduction:

- $\|\underline{\lambda}\| = 0$
- $\|\lambda t\| = \|t\|$

- $\|(tu)\| = \|t\| + \|u\|$
- $\|\langle k \rangle t\| = \|t\|$
- $\|[i/u, j]t\| = \|t\| + \|u\| + \text{cxy}(t)$ .

□

### 5.3.2. Weak normalization of the $p_2$ -calculus

**Definition 5.13.** We define a binary relation  $\uparrow$  on  $\Lambda_{ws} \times \mathbb{N}$  by:  $\uparrow(t, k)$  iff  $t = \langle k \rangle v$  or  $t = [k/v, l]w$ .

**Proposition 5.14 (Description of the  $p_2$ -normal forms).** A  $p_2$ -normal form is a term in one of the following forms:

- $\underline{n}$
- $\lambda t$  with  $t \in NF(p_2)$
- $(t u)$  with  $t, u \in NF(p_2)$
- $\langle k \rangle t$  with  $t \in NF(p_2)$
- $[i/u, j]\underline{n}$  with  $u \in NF(p_2)$
- $[i/u, j]t$  with  $t, u \in NF(p_2)$  and there is  $k$  such that  $k > i$  and  $\uparrow(t, k)$

*Proof.* By induction on  $t$ . □

**Proposition 5.15.** The  $p_2$ -calculus is weakly normalizing.

*Proof.* Let  $t$  be a  $\lambda_{ws}$ -term. We show, by induction on the complexity of  $t$ , that  $t \in WN(p_2)$ . The only difficult case is  $t = [i/u, j]v$ . By induction,  $u$  and  $v$  have normal forms  $u'$  and  $v'$  and we can reduce  $t \rightarrow^* [i/u', j]v'$ . We have to show: If  $t, u \in NF(p_2)$  then  $[i/u, j]t \in WN(p_2)$ .

By induction on the complexity of  $t$ , we show that there is  $t' \in NF(p_2)$  such that:

- $[i/u, j]t \rightarrow_{p_2}^* t'$
- If  $\uparrow(t, k)$  then  $\uparrow(t', \min(i, k))$

The non trivial cases are:

- If  $t = \underline{n}$  then  $t' = [i/u, j]\underline{n}$  is a normal form.
- If  $t = \langle k \rangle v$ :
  - If  $i < k$  then  $t' = [i/u, j]\langle k \rangle v$  is a normal form and we have  $\uparrow(t', \min(i, k))$ .
  - If  $i \geq k$  then  $[i/u, j]t \rightarrow \langle k \rangle [i - k/u, j]v$ . By induction  $[i - k/u, j]v \rightarrow^* v'$  with  $v' \in NF(p_2)$  and so  $[i/u, j]t \rightarrow^* \langle k \rangle v'$  and  $\langle k \rangle v' \in NF(p_2)$ . Clearly  $\uparrow(t', \min(i, k))$ .
- If  $t = [k/v, l]w$ :
  - If  $i < k$  then  $t' = [i/u, j]t$  is a normal form and we have  $\uparrow(t', \min(i, k))$ .
  - If  $k \leq i < k + l$  then  $[i/u, j]t \rightarrow [k/[i - k/u, j]v, l + j - 1]w$ . By induction  $[i - k/u, j]v \rightarrow^* v'$  with  $v' \in NF(p_2)$  and so  $[i/u, j]t \rightarrow^* t' = [k/v', l + j - 1]w$ . Finally  $t' \in NF(p_2)$  and  $\uparrow(t', \min(i, k))$ .
  - If  $k + l \leq i$  then  $[i/u, j]t \rightarrow [k/[i - k/u, j]v, l][i - l + 1/u, j]w$ . By induction,

$[i - k/u, j]v \rightarrow^* v'$  with  $v' \in NF(p_2)$ , and  $[i - l + 1/u, j]w \rightarrow^* w'$  with  $w' \in NF(p_2)$ . Thus:

$$[i/u, j]t \rightarrow_{p_2}^* t' = [k/v', l]w'$$

Clearly  $\uparrow (t', \min(i, k))$ . The only thing to prove is that  $t'$  is a  $p_2$ -normal form.  $w$  is necessarily of one of the following forms:

- $w = \underline{m}$  and  $w' = [i - l + 1/u, j]w$  but  $k < i - l + 1$ , and then  $t' \in NF(p_2)$ .
- $\uparrow (w, n)$  with  $k < n$ . By induction hypothesis,  $\uparrow (w', \min(i - l + 1, n))$ . As  $k < i - l + 1$ , we have  $k < \min(n, i - l + 1)$  and  $t'$  is a  $p_2$ -normal form. □

## 6. Confluence on open terms

In this section, we show that the  $\lambda_{ws}$ -calculus is confluent on terms with metavariables.

### 6.1. The calculus with metavariables

We enlarge the syntax of terms by allowing metavariables (denoted by  $a, b, \dots$ ).

**Definition 6.1.**  $\Lambda_{ws_o}$  is the set of terms with metavariables which are defined by:

$$t ::= \underline{n} \mid a \mid \lambda t \mid (t t) \mid \langle k \rangle t \mid [i/t, j]t \text{ with } a \text{ a metavariable and } n, i, j, k \in \mathbb{N}$$

**Definition 6.2.** The  $\lambda_{ws_o}$ -calculus is the reduction on  $\Lambda_{ws_o}$  defined by the rules of the  $\lambda_{ws}$ -calculus. The  $ws_o$ -calculus is the reduction defined by the rules of the  $ws$ -calculus.

**Proposition 6.3.** The  $ws_o$ -calculus is strongly normalizing.

*Proof.* It is an immediate consequence of the strong normalization of the  $ws$ -calculus. □

### 6.2. Confluence of the $ws_o$ -calculus

**Proposition 6.4.** The  $ws_o$ -calculus is locally confluent.

*Proof.* By analyzing the critical pairs (see (Guillaume, 1999b)). □

**Theorem 6.5.** The  $ws_o$ -calculus is confluent.

*Proof.* The  $ws_o$ -calculus is locally confluent (proposition 6.4) and strongly normalizing (proposition 6.3). The result follows from Newman's lemma. □

### 6.3. Confluence of the $\lambda_{ws_o}$ -calculus

In order to show the confluence of the  $\lambda_{ws_o}$ -calculus, we use the interpretation method (Hardin, 1989). This allows to restrict ourselves to confluence on  $ws_o$ -normal forms.

**Lemma 6.6 (Description of the  $ws_o$ -normal forms).**

The terms  $NF(ws_o)$  are described by the following grammar:

$$t ::= u \mid \langle k \rangle u$$

$$u ::= \underline{u} \mid [i_1/t, j_1] \dots [i_m/t, j_m] a \mid \lambda t \mid (t t)$$

with  $m \geq 0$ ,  $a$  a metavariable and  $k, n, i_1, j_1, \dots, i_m, j_m \in \mathbb{N}$  such that  $i_1 < \dots < i_m$ .

*Proof.* Trivial. □

We denote by  $ws_o(t)$  the  $ws_o$ -normal form of  $t$ . Remark, in the previous definition, that the term  $[i_1/t, j_1] \dots [i_m/t, j_m] a$  could be written  $S\{a\}$  with  $S$  a substitutive context, but we have to say that the terms inside the substitutions are  $ws_o$ -normal forms.

**Definition 6.7.** On the set  $NF(ws_o)$ , we define a reduction  $b'$  by:

$$t \longrightarrow_{b'} u \text{ iff there is } t' \in \Lambda_{ws_o} \text{ such that } t \longrightarrow_b t' \text{ and } u = ws_o(t').$$

**Theorem 6.8.** The  $\lambda_{ws_o}$ -calculus is confluent.

*Proof.* We will check:

- (1) If  $t \longrightarrow_{\lambda_{ws_o}} u$  then  $ws_o(t) \longrightarrow_{b'}^* ws_o(u)$  (proposition 6.15).
- (2)  $b'$  is confluent (proposition 6.20).

The following diagram (the interpretation method) then gives the confluence of the  $\lambda_{ws_o}$ -calculus.

□

**Corollary 6.9.** The  $\lambda_{ws}$ -calculus is confluent.

In order to prove (1) and (2) above we need some lemmas. The following definition will simplify the proofs.

**Definition 6.10.** We define a function  $\uparrow$  from  $\Lambda_{ws_o}$  to  $\overline{\mathbb{N}}$  by:

- $\uparrow(a) = \infty$ ,
- $\uparrow([i/u, j]t) = i$ ,
- $\uparrow(t) = -\infty$  in the other cases.

**Remark 6.11.** This function allows to write easily the condition under which a substitution can go down in a term: if  $t, u$  are  $ws_o$ -normal forms then

$$[i/u, j]t \in NF(ws_o) \text{ iff } i < \uparrow(t)$$

**Lemma 6.12.** Let  $t, u \in NF(ws_o)$ . Then,  $\uparrow(ws_o([i/u, j]t)) = \min(i, \uparrow(t))$ .

*Proof.* Trivial.  $\square$

### 6.3.1. The calculus on the $ws_o$ -normal forms

**Lemma 6.13.** Let  $t, u, u' \in NF(ws_o)$  be such that  $u \rightarrow_{b'}^* u'$ . Then,

$$ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u', j]t).$$

*Proof.* By an immediate induction on the length of the derivation  $u \rightarrow_{b'}^* u'$ , we may assume that  $u \rightarrow_{b'} u'$ . The proof is by induction on  $t$ . The only interesting case is  $t = [k/v, l]w$ .

— If  $i < k$  then

$$\begin{aligned} ws_o([i/u, j][k/v, l]w) &= [i/u, j][k/v, l]w \\ ws_o([i/u', j][k/v, l]w) &= [i/u', j][k/v, l]w \end{aligned}$$

Thus,

$$ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u', j]t)$$

— If  $k \leq i < k + l$  then

$$\begin{aligned} ws_o([i/u, j][k/v, l]w) &= [k/ws_o([i - k/u, j]v), l + j - 1]w \\ ws_o([i/u', j][k/v, l]w) &= [k/ws_o([i - k/u', j]v), l + j - 1]w \end{aligned}$$

By induction hypothesis,  $ws_o([i - k/u, j]v) \rightarrow_{b'}^* ws_o([i - k/u', j]v)$  and then

$$ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u', j]t)$$

— If  $k + l \leq i$ .

$$ws_o([i/u, j][k/v, l]w) = ws_o([k/[i - k/u, j]v, l][i - l + 1/u, j]w)$$

Since  $t \in NF(ws_o)$ , we have  $k < \uparrow(w)$  so  $k < \min(\uparrow(w), i + l - 1)$ . Lemma 6.12 ensures that  $k < \uparrow(ws_o([i - l + 1/u, j]w))$ . We get

$$ws_o([i/u, j][k/v, l]w) = [k/ws_o([i - k/u, j]v), l]ws_o([i - l + 1/u, j]w)$$

In the same way,

$$ws_o([i/u', j][k/v, l]w) = [k/ws_o([i - k/u', j]v), l]ws_o([i - l + 1/u', j]w)$$

By induction hypothesis,  $ws_o([i - k/u, j]v) \rightarrow_{b'}^* ws_o([i - k/u', j]v)$  and  $ws_o([i - l + 1/u, j]w) \rightarrow_{b'}^* ws_o([i - l + 1/u', j]w)$ . Finally,

$$ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u', j]t).$$

$\square$

**Lemma 6.14.** Let  $t, t', u \in NF(ws_o)$  be such that  $t \rightarrow_{b'}^* t'$ . Then

$$ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u, j]t')$$

*Proof.* By an immediate induction on the length of the derivation  $t \rightarrow_{b'}^* t'$ , we may assume that this reduction is one step. The proof is by induction on  $t$ . The only interesting case is when the redex is at the root of  $t$ :  $t = (\langle k \rangle \lambda v w)$  and  $t' = ws_o([0/w, k]v)$ .

- If  $i < k$  then
 
$$\begin{aligned} ws_o([i/u, j]t) &= (\langle k + j - 1 \rangle \lambda v ws_o([i/u, j]w)) \\ ws_o([i/u, j]t') &= ws_o([i/u, j]ws_o([0/w, k]v)) \\ &= ws_o([i/u, j][0/w, k]v) \\ &= ws_o([0/[i/u, j]w, k + j - 1]v) \end{aligned}$$
 Thus,  $ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u, j]t')$ .
- If  $i \geq k$  then
 
$$\begin{aligned} ws_o([i/u, j]t) &= (\langle k \rangle \lambda ws_o([i - k + 1/u, j])v ws_o([i/u, j]w)) \\ ws_o([i/u, j]t') &= ws_o([i/u, j]ws_o([0/w, k]v)) \\ &= ws_o([i/u, j][0/w, k]v) \\ &= ws_o([0/[i/u, j]w, k][i - k + 1/u, j]v) \end{aligned}$$
 Thus,  $ws_o([i/u, j]t) \rightarrow_{b'}^* ws_o([i/u, j]t')$ .

□

**Proposition 6.15.** If  $t \rightarrow_{\lambda_{ws_o}} u$  then  $ws_o(t) \rightarrow_{b'}^* ws_o(u)$ .

*Proof.* If the reduction  $t \rightarrow_{\lambda_{ws_o}} u$  is a  $ws_o$ -reduction, then the uniqueness of  $ws_o$ -normal forms gives the result. Assume then that  $t \rightarrow_b u$ . The proof is by induction on  $t$ :

- If  $t$  does not begin with a substitution, the difficult case is when the reduction is at the root, i.e.  $t = (\langle k \rangle \lambda v w)$  and  $u = [0/w, k]v$ . We get

$$ws_o(t) = (\langle k \rangle \lambda ws_o(v) ws_o(w)) \rightarrow_{b'} ws_o([0/ws_o(w), k]ws_o(v)) = ws_o(u)$$

- If  $t = [i/w, j]v$  and  $u = [i/w', j]v$  with  $w \rightarrow_b w'$  then, by the induction hypothesis,  $ws_o(w) \rightarrow_{b'}^* ws_o(w')$ . By lemma 6.13, we have

$$ws_o([i/ws_o(w), j]ws_o(v)) \rightarrow_{b'}^* ws_o([i/ws_o(w'), j]ws_o(v))$$

and then  $ws_o(t) \rightarrow_{b'}^* ws_o(u)$ .

- If  $t = [i/w, j]v$  and  $u = [i/w, j]v'$  with  $v \rightarrow_b v'$  then, by the induction hypothesis,  $ws_o(v) \rightarrow_{b'}^* ws_o(v')$ . By lemma 6.14, we have

$$ws_o([i/ws_o(w), j]ws_o(v)) \rightarrow_{b'}^* ws_o([i/ws_o(w), j]ws_o(v'))$$

and then  $ws_o(t) \rightarrow_{b'}^* ws_o(u)$ .

□

### 6.3.2. Confluence of the reduction on $ws_o$ -normal forms

To show the confluence of the  $b'$ -reduction, we use the usual method of parallel reductions.

**Definition 6.16.** We define the *parallel reduction*  $\Longrightarrow$  on the set  $NF(ws_o)$  by:

- $\underline{n} \Longrightarrow \underline{n}$ .

- If  $t_1 \implies t_2$  then  $\lambda t_1 \implies \lambda t_2$ .
- If  $t_1 \implies t_2$  and  $u_1 \implies u_2$  then  $(t_1 u_1) \implies (t_2 u_2)$ .
- If  $t_1 \implies t_2$  then  $\langle k \rangle t_1 \implies \langle k \rangle t_2$ .
- If  $t_k \implies u_k$  for  $1 \leq k \leq n$  and  $i_1 < \dots < i_n$   
then  $[i_1/t_1, j_1] \dots [i_n/t_n, j_n] a \implies [i_1/u_1, j_1] \dots [i_n/u_n, j_n] a$ .
- If  $t_1 \implies t_2$  and  $u_1 \implies u_2$  then  $(\lambda t_1 u_1) \implies ws_o([0/u_2, 0]t_2)$ .
- If  $t_1 \implies t_2$  and  $u_1 \implies u_2$  then  $(\langle k \rangle \lambda t_1 u_1) \implies ws_o([0/u_2, k]t_2)$ .

**Lemma 6.17.**  $\implies^* = \longrightarrow_{b'}^*$ .

*Proof.* It is easy to see that if  $t \longrightarrow_{b'} u$  then  $t \implies u$ . Conversely, assume that  $t \implies u$ . We use an induction on the definition of  $t \implies u$ . The hardest case is the last one:

Let  $t = (\langle k \rangle \lambda v w)$  and  $u = ws_o([0/w', k]v')$  with  $v \implies v'$  and  $w \implies w'$ . By induction hypothesis,  $v \longrightarrow_{b'}^* v'$  and  $w \longrightarrow_{b'}^* w'$ . Then,

$$t = (\langle k \rangle \lambda v w) \longrightarrow_{b'}^* (\langle k \rangle \lambda v' w) \longrightarrow_{b'}^* (\langle k \rangle \lambda v' w') \longrightarrow_{b'} u = ws_o([0/w', k]v').$$

□

**Lemma 6.18.** Let  $t, u \in NF(ws_o)$ . If  $t \implies t'$  and  $u \implies u'$ , then  $ws_o([i/u, j]t) \implies ws_o([i/u', j]t')$ .

*Proof.* Let  $T = ws_o([i/u, j]t)$  and  $T' = ws_o([i/u', j]t')$ . We show  $T \implies T'$  by induction on the definition of  $t \implies t'$

The difficult cases are:

- $t = [k/v, l]w$  and  $t' = [k/v', l]w'$  with  $v \implies v'$  and  $w \implies w'$ .
  - If  $i < k$  then  $[i/u, j]t$  and  $[i/u', j]t'$  are already  $ws_o$ -normal forms and so

$$T = [i/u, j][k/v, l]w \implies T' = [i/u', j][k/v', l]w'$$

- If  $k \leq i < k + l$  then

$$T = [k/ws_o([i - k/u, j]v), l + j - 1]w \implies T' = [k/ws_o([i - k/u', j]v'), l + j - 1]w'$$

By the induction hypothesis,  $ws_o([i - k/u, j]v) \implies ws_o([i - k/u', j]v')$  and  $T \implies T'$ .

- If  $i \geq k + l$  then

$$T = ws_o([k/[i - k/u, j]v, l][i - l + 1/u, j]w)$$

$$T' = ws_o([k/[i - k/u', j]v', l][i - l + 1/u', j]w')$$

By the induction hypothesis,  $ws_o([i - k/u, j]v) \implies ws_o([i - k/u', j]v')$  and  $ws_o([i - l + 1/u, j]w) \implies ws_o([i - l + 1/u', j]w')$ . Moreover, lemma 6.12 ensures that  $\uparrow(ws_o([i - l + 1/u, j]w)) = \min(\uparrow(w), i - l + 1)$ . Since  $t \in NF(ws_o)$  we have  $k < \uparrow(w)$  and so  $k < \min(\uparrow(w), i - l + 1)$ .

$$T = [k/ws_o([i - k/u, j]v), l]ws_o([i - l + 1/u, j]w)$$

$$T' = [k/ws_o([i - k/u', j]v'), l]ws_o([i - l + 1/u', j]w')$$

Finally,  $T \implies T'$ .

—  $t = (\langle k \rangle \lambda w v)$  and  $t' = ws_o([0/w', k]v')$  with  $v \Longrightarrow v'$  and  $w \Longrightarrow w'$ .

– If  $i < k$

$$T = (\langle k + j - 1 \rangle \lambda v ws_o([i/u, j]w))$$

$$T' = ws_o([i/u', j][0/w', k]v') = ws_o([0/[i/u', j]w', k + j - 1]v')$$

By the induction hypothesis,  $ws_o([i/u, j]w) \Longrightarrow ws_o([i/u', j]w')$  so  $T \Longrightarrow T'$ .

– If  $i \geq k$

$$T = (\langle k \rangle \lambda ws_o([i - k + 1/u, j]v) ws_o([i/u, j]w))$$

$$T' = ws_o([i/u', j][0/w', k]v') = ws_o([0/[i/u', j]w', k][i - k + 1/u', j]v')$$

By the induction hypothesis,  $ws_o([i/u, j]w) \Longrightarrow ws_o([i/u', j]w')$  and  $T \Longrightarrow T'$ .

□

**Lemma 6.19.** The reduction  $\Longrightarrow$  is strongly confluent.

*Proof.* Let  $t_1, t_2, t_3 \in NF(ws_o)$  be such that  $t_1 \Longrightarrow t_2$  and  $t_1 \Longrightarrow t_3$ . We show that there is a term  $t_4$  such that  $t_2 \Longrightarrow t_4$  and  $t_3 \Longrightarrow t_4$  by induction on the complexity of  $t_1$ . The only interesting case is when  $t_1 = (\langle k \rangle \lambda u_1 v_1)$ . We consider the form of  $t_2$  and  $t_3$ .

— If  $t_2 = (\langle k \rangle \lambda u_2 v_2)$  with  $u_1 \Longrightarrow u_2$  and  $v_1 \Longrightarrow v_2$ .

– If  $t_3 = (\langle k \rangle \lambda u_3 v_3)$  with  $u_1 \Longrightarrow u_3$  and  $v_1 \Longrightarrow v_3$  the induction hypothesis gives the result.

– If  $t_3 = ws_o([0/v_3, k]u_3)$  with  $u_1 \Longrightarrow u_3$  and  $v_1 \Longrightarrow v_3$  the induction hypothesis ensures that there are  $u_4$  and  $v_4$  such that  $u_2 \Longrightarrow u_4$ ,  $u_3 \Longrightarrow u_4$ ,  $v_2 \Longrightarrow v_4$  and  $v_3 \Longrightarrow v_4$  and then

$$\begin{array}{ccc} t_1 = (\langle k \rangle \lambda u_1 v_1) & \Longrightarrow & t_2 = (\langle k \rangle \lambda u_2 v_2) \\ \Downarrow & & \Downarrow \\ t_3 = ws_o([0/v_3, k]u_3) & \xrightarrow{\text{prev. lemma}} & t_4 = ws_o([0/v_4, k]u_4) \end{array}$$

— If  $t_2 = ws_o([0/v_2, k]u_2)$  with  $u_1 \Longrightarrow u_2$  and  $v_1 \Longrightarrow v_2$ .

– If  $t_3 = (\langle k \rangle \lambda u_3 v_3)$  with  $u_1 \Longrightarrow u_3$  and  $v_1 \Longrightarrow v_3$ , we conclude as in the previous case.

– If  $t_3 = ws_o([0/v_3, k]u_3)$  with  $u_1 \Longrightarrow u_3$  and  $v_1 \Longrightarrow v_3$  the induction hypothesis ensures that there are  $u_4$  and  $v_4$  such that  $u_2 \Longrightarrow u_4$ ,  $u_3 \Longrightarrow u_4$ ,  $v_2 \Longrightarrow v_4$  and  $v_3 \Longrightarrow v_4$ , then

$$\begin{array}{ccc} t_1 = (\langle k \rangle \lambda u_1 v_1) & \Longrightarrow & t_2 = ws_o([0/v_2, k]u_2) \\ \Downarrow & & \Downarrow \text{prev. lemma} \\ t_3 = ws_o([0/v_3, k]u_3) & \xrightarrow{\text{prev. lemma}} & t_4 = ws_o([0/v_4, k]u_4) \end{array}$$

□

**Proposition 6.20.**  $b'$  is confluent.

*Proof.* The reduction  $\implies$  is strongly confluent, therefore the reduction  $\longrightarrow_{b'}^*$  is also strongly confluent and then  $b'$  is confluent (remark 2.5).  $\square$

## 7. Simulation of the $\beta$ -reduction

There is a one-one correspondence between one-step reduction in the  $\lambda_{db}$ -calculus and one-step of  $\beta$ -reduction in the  $\lambda_w$ -calculus. In order to show that the  $\lambda_{ws}$ -calculus correctly implements the  $\beta$ -reduction, we give the link with the  $\lambda_w$ -calculus. We show that any reduction of the  $\lambda_w$ -calculus can be done in the  $\lambda_{ws}$ -calculus (cf. proposition 7.3) and that any  $\lambda_{ws}$ -reduction corresponds to a  $\lambda_w$ -reduction on the  $ws$ -normal forms (cf. proposition 7.4). In this sense, our calculus has a step by step simulation of  $\beta$ .

Strictly speaking,  $\lambda_{ws}$  does not simulate the  $\lambda_{db}$ -reduction. However, as we already said in subsection 3.5,  $\lambda$ -terms with labels are efficient notations for  $\lambda$ -terms and, when the  $\lambda_{ws}$ -calculus is used as the internal representation of  $\lambda$ -terms (for the implementation of a functional language or a proof assistant), the simulation property we give here is clearly the useful one.

Finally note that  $\lambda\zeta$  only simulates big steps of reduction and that the link of the  $\lambda_{ws}$ -calculus with the  $\beta$ -reduction is much simpler than the one of the  $SKInT$ -calculus:  $\lambda$ -terms trivially are  $\lambda_{ws}$ -terms whereas, in  $SKInT$ , CPS transformation and abstraction algorithm are necessary to get the translation.

The following property is trivial:

**Proposition 7.1.** The  $ws$ -normal forms are the terms of  $\Lambda_w$ , i.e. they are given by the grammar:

$$\begin{aligned} t &::= u \mid \langle k \rangle u && \text{with } k \in \mathbb{N} \\ u &::= \underline{n} \mid \lambda t \mid (t t) \end{aligned}$$

The set of  $ws$ -normal forms will be denoted either by  $NF(ws)$  or by  $\Lambda_w$ .

The next lemma gives the relation between the implicit substitution (cf. definition 3.5) and the explicit one.

**Lemma 7.2.** Let  $t, u \in NF(ws)$ . Then  $\{i/u, j\}t = p([i/u, j]t)$ .

*Proof.* By induction on the complexity of  $t$ .  $\square$

The following proposition shows that any  $\lambda_{ws}$ -reduction can be simulated in the  $\lambda_w$ -calculus.

**Proposition 7.3.** Let  $t, u \in NF(ws)$ . If  $t \longrightarrow_{\lambda_w} u$  then  $t \longrightarrow_{\lambda_{ws}}^* u$ .

*Proof.* We consider the case  $t \longrightarrow_{\beta_2} u$  (the  $\beta_1$  rule is simpler). Let  $t = C \llbracket \langle k \rangle \lambda v w \rrbracket$  and  $u = m(C \llbracket 0/w, k \rrbracket t \rrbracket)$ .

— If the context  $C$  ends with a label:  $C \llbracket \cdot \rrbracket = C' \llbracket \langle l \rangle \cdot \rrbracket$  then

$$t = C' \llbracket \langle l \rangle \langle k \rangle \lambda v w \rrbracket \longrightarrow_{b_2} C' \llbracket \langle l \rangle [0/w, k] t \rrbracket \longrightarrow_{ws}^* C' \llbracket ws \langle l \rangle [0/w, k] t \rrbracket$$

with remark 4.5 and lemma 7.2,

$$ws \langle l \rangle [0/w, k] t = m(p(\langle l \rangle [0/w, k] t)) = m(\langle l \rangle p([0/w, k] t)) = m(\langle l \rangle \{0/w, k\} t)$$

Moreover, as  $C'$  cannot end with a label, we have  $u = m(C'\{\langle l \rangle\{0/w, k\}t\}) = C'\{m(\langle l \rangle\{0/w, k\}t)\}$  and thus  $t \rightarrow_{\lambda_{ws}}^* u$ .

— If the context  $C$  does not end with a label:

$$t = C\{\langle k \rangle \lambda v\} \rightarrow_{b_2} C\{[0/w, k]t\} \rightarrow_{ws}^* C\{ws([0/w, k]t)\}$$

with remark 4.5 and lemma 7.2,

$$ws([0/w, k]t) = m(p([0/w, k]t)) = m(\{0/w, k\}t)$$

Moreover,  $u = m(C\{\{0/w, k\}t\}) = C\{m(\{0/w, k\}t)\}$  and thus  $t \rightarrow_{\lambda_{ws}}^* u$ . □

Conversely, we can show that any  $\lambda_{ws}$ -reduction of a term  $t$  corresponds to a  $\lambda_w$ -reduction of the  $ws$ -normal form of  $t$ .

**Proposition 7.4.** Let  $t, u \in \Lambda_{ws}$ . If  $t \rightarrow_{\lambda_{ws}} u$  then  $ws(t) \rightarrow_{\lambda_w}^* ws(u)$ .

*Proof.* This is a particular case of proposition 6.15 with terms without metavariables. Just remark that, on terms without metavariables, the reductions  $\lambda_w$  and  $b'$  (cf. definition 6.7) are the same. □

## 8. Preservation of strong normalization

In this section, we give the proof of the preservation of the strong normalization. This property is the hardest one. Since most of the calculi with composition of substitutions fail to have the PSN property, a new technique has to be invented. This technique is inspired by the notion of standard reduction of the  $\lambda$ -calculus.

The labels prevent the loss of information which appears in the  $\lambda_{s_e}$ -calculus and in the  $\lambda\sigma$ -calculus. The rules  $c_1$  and  $c_2$  are exactly the rules needed to obtain both MC and PSN.

As in  $\lambda_{s_e}$ , the Melliès counter-example is avoided with the side condition of the interaction rules: a term  $[i/u, j][k/v, l]t$  is a redex (rule  $c_1$  or  $c_2$ ) if and only if  $i \geq k$ . In  $\lambda_{s_e}$ , new rules are added for the propagation of updatings. We have seen, in subsection 2.3, that one of these rules ( $\phi\sigma$ ) causes the failure of PSN. In  $\lambda_{ws}$ , this rule is useless, since there no need to move updatings down. In this way,  $\lambda_{ws}$  avoids the  $\lambda_{s_e}$  counter-example.

The key point of the proof is lemma 8.15. This lemma ensures that it is always possible to do a useful composition to get MC (first point) and that it is never possible to do a useless and dangerous (for PSN) composition (second point). The corresponding lemma would be false for  $\lambda_{s_e}$  and  $\lambda\sigma$ . In other words, unlike  $\lambda_{s_e}$ , the substitution have a good behavior: if a term contains a subterm  $[i/u, j][k/v, l]t$  with  $i < k$  (no possible interaction) then in all future reducts of  $t$  it will still be impossible to make these two substitutions interact.

The general idea of the proof is the following: we construct an infinite derivation without composition from an infinite derivation in the  $\lambda_{ws}$ -calculus. This allows to show that we never get artificial terms of the form  $[\dots u \dots]u$ .

In the subsection 8.1, we give the sketch of the proof. Sections 8.2 and 8.3 give the definitions and the main tools used in the proof. The key lemma is proved in section 8.4.

### 8.1. Sketch of the proof

Let  $t \in NF(ws)$  be such that  $t \in SN(\lambda_w)$ . We show that  $t$  is strongly normalizable in the  $\lambda_{ws}$ -calculus.

**Theorem 8.1.**  $SN(\lambda_w) \subset SN(\lambda_{ws})$ .

For technical reasons, it is easier to work on  $p$ -normal forms rather than on  $ws$ -normal forms (the  $p$ -calculus is the  $ws$ -calculus without the mixing rule  $m$ ). We thus prove the (stronger) result: If  $t \in NF(p)$  and  $m(t) \in SN(\lambda_w)$  then  $t \in SN(\lambda_{ws})$  which is a consequence of the following:

**Lemma 8.2 (key lemma).** Let  $t \in NF(p) \setminus SN(\lambda_{ws})$ . There is  $u \in NF(p)$  such that  $u \notin SN(\lambda_{ws})$  and  $m(t) \rightarrow_{\lambda_w} m(u)$ .

*Proof of the theorem 8.1.* Let  $t \in NF(p)$  be such that  $m(t) \in SN(\lambda_w)$  and  $t \notin SN(\lambda_{ws})$ . We can choose  $t$  such that the length of the longest  $\lambda_w$ -reduction of  $m(t)$  is minimal. The key lemma gives a term  $u$  such that the length of the longest  $\lambda_w$ -reduction of  $m(u)$  is shorter and thus we get a contradiction. We have proved: If  $t \in NF(p)$  and  $m(t) \in SN(\lambda_w)$  then  $t \in SN(\lambda_{ws})$ . The theorem is a particular case of this result with  $t \in NF(ws)$  since, for such a  $t$ ,  $m(t) = t$ .  $\square$

The key lemma is proved by induction. The difficult case is when the head of  $t$  is  $(\langle k_1 \rangle \dots \langle k_n \rangle \lambda v w)$  and  $v, w$  as well as all arguments of the head redex are  $\lambda_{ws}$ -strongly normalizable. The term  $u$  (given by the lemma) is defined by the following sequence of reductions:

- if  $n > 1$ , contract the labels  $\langle k_j \rangle$ ,
- reduce the head redex,
- take the  $p$ -normal form.

The key point is to show that if  $t$  has an infinite  $\lambda_{ws}$ -reduction, then so does  $u$ . For the two first steps (contraction of the labels and reduction of the head redex), it is easy to show that infinite reductions are preserved.

For the last step (propagation of the substitution), we use the projection lemma on an extended syntax of the  $\lambda_{ws}$ -calculus. This syntax allows to keep track of the reducts of the substitution created by reduction of the head redex. (subsection 8.3).

### 8.2. Definitions

We give here the definitions which are used in the definition of the term  $u$  of the key lemma.

**Definition 8.3.**

We define particular contexts and terms:

— The *feet*  $F$  and the *bodies*  $B$  are contexts defined by the grammars:

$$F = \{\cdot\} \mid \langle k_1 \rangle \dots \langle k_n \rangle \lambda F$$

$$B = \{\cdot\} \mid \langle k \rangle B \mid (B t) \text{ with } t \in NF(p)$$

— The *heads*  $H$  are terms of the form  $\underline{n}$  or  $\langle \langle k_1 \rangle \dots \langle k_m \rangle \lambda u v \rangle$  with  $m \geq 0$  and  $u, v \in NF(p)$ .

**Lemma 8.4 (canonical decomposition of the  $p$ -normal-forms).**

Each term  $t \in NF(p)$  has a canonical decomposition  $t = F \{B \{H\}\}$ .

*Proof.* By induction on  $t$ . □

**Example 8.5.** Let  $t = \lambda \langle 2 \rangle \langle 3 \rangle \lambda \langle 1 \rangle \langle \langle 1 \rangle \langle 4 \rangle \langle \langle 2 \rangle \langle \langle 1 \rangle \langle 4 \rangle \lambda \underline{0} u \rangle t_1 \rangle t_2$ ,

The two main points are the following: (1) The interesting reductions of  $t$  are the ones of  $B \{H\}$ . This is due to the fact that a foot is either empty or is a context finishing with a  $\lambda$ . (2) An important information is the level where the substitution created by the reduction of the head redex appears in the term  $B \{H\}$ . This will be defined (cf. below) as the depth of  $B$ .

**Definition 8.6.**

- 1 Let  $B$  be a body,  $Arg(B)$  (the set of *arguments* of  $B$ ) is defined by:
  - If  $B = \{\cdot\}$  then  $Arg(B) = \emptyset$ .
  - If  $B = \langle k \rangle B'$  then  $Arg(B) = Arg(B')$ .
  - If  $B = (B' t)$  then  $Arg(B) = Arg(B') \cup \{t\}$ .
- 2 Let  $B$  be a body.  $|B|$  (the *depth* of  $B$ ) is defined by:

- $|\llbracket \cdot \rrbracket| = 0$ .
- $|\langle k \rangle B| = |B| + k$ .
- $|(B t)| = |B|$ .

Let  $t$  be the term of example 8.5, then  $Arg(B) = \{t_1, t_2\}$  and  $|B| = 8$ .

The following lemma will be used in the proof of the key lemma.

**Lemma 8.7.** Let  $t \in NF(p)$  and  $t', t'' \in \Lambda_{ws}$  be such that  $t \xrightarrow*_m t' \xrightarrow_b t''$ . Then  $m(t) \xrightarrow{\lambda_w} m(u)$  where  $u = p(t'')$ .

*Proof.* By induction on  $t$ . If  $t = \langle k_1 \rangle \dots \langle k_n \rangle \lambda v$  or  $t = \langle k_1 \rangle \dots \langle k_n \rangle (v w)$  and the  $b$ -reduction is in  $v$  or  $w$ , the induction hypothesis immediately gives the result.

The only difficult case is  $t = \langle k_1 \rangle \dots \langle k_n \rangle (\langle l_1 \rangle \dots \langle l_m \rangle \lambda v w)$  and the  $b$ -reduction is the one of the head redex. Then,

$$\begin{aligned} m(t) &= \langle k \rangle (\langle l \rangle \lambda m(v) m(w)) \text{ with } k = \sum_{i=0}^n k_i \text{ and } l = \sum_{i=0}^m l_i \\ t' &= \langle k'_1 \rangle \dots \langle k'_{n'} \rangle (\langle l \rangle \lambda v' w') \text{ with } v \xrightarrow*_m v', w \xrightarrow*_m w' \text{ and } k = \sum_{i=0}^{n'} k'_i. \\ t'' &= \langle k'_1 \rangle \dots \langle k'_{n'} \rangle [0/w', l]v'. \\ m(u) &= m(p(t'')) = ws(t'') = ws(\langle k \rangle [0/w', l]v'). \end{aligned}$$

Finally,  $m(t) \xrightarrow{\lambda_w} ws(\langle k \rangle [0/w, l]v) = m(u)$  (because the  $ws$ -calculus is confluent and normalizing).  $\square$

### 8.3. Preservation of infinite reductions by propagation

The goal of this subsection is to prove the following lemma; it is the hardest part of the proof. The meaning of this lemma is that the infinite reduction is preserved by the propagation of the head substitution.

**Lemma 8.8.** Let  $t = B \llbracket [0/w, l]v \rrbracket$  where  $v, w \in NF(p)$ . Assume that  $v, w$  and the arguments of  $B$  are  $\lambda_{ws}$ -strongly normalizable. If  $t$  has an infinite  $\lambda_{ws}$ -reduction then  $p(t)$  also has an infinite  $\lambda_{ws}$ -reduction.

The idea of the proof is the following: let  $u = p(t)$ . In order to translate the reduction  $t \longrightarrow t_1 \longrightarrow t_2 \longrightarrow \dots$  into a reduction  $u \longrightarrow u_1 \longrightarrow u_2 \longrightarrow \dots$ , we will tag the reducts of the substitution  $[0/w, l]$  and write them  $\llbracket [0/w, l] \rrbracket$ . Then, in any reduct of  $t$ , there are two kinds of substitutions: the tagged ones (denoted  $\llbracket \dots \rrbracket$ ) which are reducts of the head substitution of  $t$  and the other ones (denoted  $[\dots]$ ) which are created during the reduction.

The key point (which allows to construct the derivation of  $u$ ) consists in proving the following properties of the  $t_i$ : they ensure that, in each  $t_i$  we can move down the substitutions  $\llbracket \dots \rrbracket$  without moving the substitutions  $[\dots]$  and thus define  $u_i$  as the “normal form of  $t_i$  by tagged propagation”.

- If a subterm is  $\llbracket [i/w', j]v' \rrbracket$  then  $v'$  and  $w'$  contain no substitution  $\llbracket \dots \rrbracket$ .
- Substitutions  $\llbracket \dots \rrbracket$  are always “higher” than the  $[\dots]$ , i.e. if the subterm is  $\llbracket \dots \rrbracket [\dots] w$  then we can always compose the substitutions. Conversely, if the subterm is  $[\dots] \llbracket \dots \rrbracket w$ , the composition is never possible.

— If a subterm is  $\llbracket i/w', j \rrbracket v'$  then  $w'$  is strongly normalizable.

The first property comes from the syntax of the  $\lambda_{w_s}^\diamond$ -calculus (cf. 8.3.1). The two others are proved in subsection 8.3.2 and are derived from the notion of well-tagged terms. Finally, it will remain to check that the terms  $u_i$  give an infinite  $\lambda_{w_s}$ -reduction of  $u$ .

### 8.3.1. The tagged reductions

**Definition 8.9 (The  $\lambda_{w_s}^\diamond$ -calculus).** The set of terms of the  $\lambda_{w_s}^\diamond$ -calculus (denoted by  $\Lambda_{w_s}^\diamond$ ) is defined by:

$$t = \underline{n} \mid \lambda t \mid (tt) \mid \langle k \rangle t \mid [i/t, j]t \mid \llbracket i/u, j \rrbracket v \text{ with } n, i, j, k \in \mathbb{N} \text{ and } u, v \in \Lambda_{w_s}.$$

The rules of the  $\lambda_{w_s}^\diamond$ -calculus are those of the  $\lambda_{w_s}$ -calculus with the additional rules:

$$\begin{array}{llll} l_\diamond & \llbracket i/u, j \rrbracket \lambda t & \longrightarrow & \lambda \llbracket i + 1/u, j \rrbracket t \\ a_\diamond & \llbracket i/u, j \rrbracket (t v) & \longrightarrow & (\llbracket i/u, j \rrbracket t \llbracket i/u, j \rrbracket v) \\ e_{1\diamond} & \llbracket i/u, j \rrbracket \langle k \rangle t & \longrightarrow & \langle k + j - 1 \rangle t \quad i < k \\ e_{2\diamond} & \llbracket i/u, j \rrbracket \langle k \rangle t & \longrightarrow & \langle k \rangle \llbracket i - k/u, j \rrbracket t \quad k \leq i \\ n_{1\diamond} & \llbracket i/u, j \rrbracket \underline{n} & \longrightarrow & \underline{n} \quad n < i \\ n_{2\diamond} & \llbracket i/u, j \rrbracket \underline{n} & \longrightarrow & \langle i \rangle u \quad n = i \\ n_{3\diamond} & \llbracket i/u, j \rrbracket \underline{n} & \longrightarrow & \underline{n + j - 1} \quad i < n \\ c_{1\diamond} & \llbracket i/u, j \rrbracket [k/v, l]t & \longrightarrow & [k/\llbracket i - k/u, j \rrbracket v, l + j - 1]t \quad k \leq i < k + l \\ c_{2\diamond} & \llbracket i/u, j \rrbracket [k/v, l]t & \longrightarrow & [k/\llbracket i - k/u, j \rrbracket v, l] \llbracket i - l + 1/u, j \rrbracket t \quad k + l \leq i \end{array}$$

It is easy to check that the set  $\Lambda_{w_s}^\diamond$  is closed under this reduction: the only constraint imposed by the syntax is that the subterms under or inside a tagged substitution are  $\lambda_{w_s}$ -terms (i.e. without tagged substitution). This constraint is clearly preserved by the new rules.

**Definition 8.10.** The  $\diamond$ -calculus is the calculus on the set  $\Lambda_{w_s}^\diamond$  which contains the rules of propagation of tagged substitutions:  $l_\diamond$ ,  $a_\diamond$ ,  $e_\diamond$ ,  $n_\diamond$  and  $c_\diamond$ .

**Remark 8.11.** Note that the following rules

$$\begin{array}{llll} c'_{1\diamond} & \llbracket i/u, j \rrbracket [k/v, l]t & \longrightarrow & [k/\llbracket i - k/u, j \rrbracket v, l + j - 1]t \quad k \leq i < k + l \\ c'_{2\diamond} & \llbracket i/u, j \rrbracket [k/v, l]t & \longrightarrow & [k/\llbracket i - k/u, j \rrbracket v, l] \llbracket i - l + 1/u, j \rrbracket t \quad k + l \leq i \end{array}$$

which would be natural in a general framework are missing in the  $\lambda_{w_s}^\diamond$ -calculus. We will have to consider only well-tagged terms (cf. below) of the  $\lambda_{w_s}^\diamond$ -calculus and these terms do not contain any  $c'_{1\diamond}$ -redex or  $c'_{2\diamond}$ -redex. These rules are thus useless.

8.3.2. *The well-tagged terms*

Here, we formalize the following intuitive fact: in the terms that we are interested in, the tagged substitutions are always higher than the others. We actually define a more general property which is preserved by reduction.

The relation  $\mathcal{H}$  between a term (with tagged substitutions) and an integer means that any untagged substitution has a small enough index if a tagged substitution occurs below. The integer gives the depth where the tagged substitution (if any) is in the term.

The relation  $\mathcal{B}$  between a term (without tagged substitutions) and an integer means that any untagged substitution which occurs under a tagged one has a small enough index, allowing thus the tagged substitution to be propagated.

**Definition 8.12.** We define the binary relations by:

—  $\mathcal{B}$  on  $\Lambda_{ws} \times \mathbb{N}$

–  $\mathcal{B}(\underline{n}, m)$

–  $\mathcal{B}(\lambda u, m)$  iff  $\mathcal{B}(u, m + 1)$

–  $\mathcal{B}((u v), m)$  iff  $\mathcal{B}(u, m)$  and  $\mathcal{B}(v, m)$

–  $\mathcal{B}(\langle i \rangle u, m)$  iff  $\begin{cases} i \leq m \text{ and } \mathcal{B}(u, m - i) \\ \text{or} \\ i > m \end{cases}$

–  $\mathcal{B}([i/u, j]v, m)$  iff  $\begin{cases} i \leq m < i + j \text{ and } \mathcal{B}(u, m - i) \\ \text{or} \\ i + j \leq m \text{ and } \mathcal{B}(u, m - i) \text{ and } \mathcal{B}(v, m - j + 1) \end{cases}$

—  $\mathcal{H}$  on  $\Lambda_{ws}^\circ \times \mathbb{N}$

–  $\mathcal{H}(\underline{n}, m)$

–  $\mathcal{H}(\lambda u, m)$  iff  $\mathcal{H}(u, m + 1)$

–  $\mathcal{H}((u v), m)$  iff  $\mathcal{H}(u, m)$  and  $\mathcal{H}(v, m)$

–  $\mathcal{H}(\langle i \rangle u, m)$  iff  $\begin{cases} i \leq m \text{ and } \mathcal{H}(u, m - i) \\ \text{or} \\ i > m \text{ and } u \in \Lambda_{ws} \end{cases}$

–  $\mathcal{H}([i/u, j]v, m)$  iff  $\begin{cases} m < i \text{ and } u \in \Lambda_{ws} \text{ and } v \in \Lambda_{ws} \\ \text{or} \\ i \leq m < i + j \text{ and } \mathcal{H}(u, m - i) \text{ and } v \in \Lambda_{ws} \\ \text{or} \\ i + j \leq m \text{ and } \mathcal{H}(u, m - i) \text{ and } \mathcal{H}(v, m - j + 1) \end{cases}$

–  $\mathcal{H}([i/u, j]v, m)$  iff  $i = m, u \in \Lambda_{ws}, u \in SN(\lambda_{ws})$  and  $\mathcal{B}(v, m)$

**Definition 8.13.** A term  $t \in \Lambda_{ws}^\circ$  is *well-tagged* if there is an integer  $m$  such that  $\mathcal{H}(t, m)$ . The set of well-tagged terms is denoted by  $WT$ .

**Remark 8.14.** The following facts are immediate (by induction on  $t$ ):

— If  $t \in NF(p)$  (i.e.  $t$  contains no substitution) then, for all  $m \in \mathbb{N}$ , we have  $\mathcal{B}(t, m)$ .

— If  $t \in \Lambda_{ws}$  (i.e.  $t$  contains no tagged substitution) then, for all  $m \in \mathbb{N}$ , we have  $\mathcal{H}(t, m)$ .

— If  $t \in WT$  then, for all  $u$  subterm of  $t$ , we have  $u \in WT$ .

The following lemma gives the desired properties of well-tagged terms.

**Lemma 8.15.** Let  $t$  be a well-tagged term.

- 1 If  $\llbracket i/u, j \rrbracket \llbracket k/v, l \rrbracket w$  is a subterm of  $t$ , then  $i \geq k$  (i.e. the subterm is a  $c_{1\circ}$ -redex or a  $c_{2\circ}$ -redex).
- 2 If  $\llbracket i/u, j \rrbracket \llbracket k/v, l \rrbracket w$  is a subterm of  $t$ , then  $i < k$  (i.e. there is no  $c'_{1\circ}$ -redex or  $c'_{2\circ}$ -redex (cf. remark 8.11)).

*Proof.*

- 1 Let  $t' = \llbracket i/u, j \rrbracket \llbracket k/v, l \rrbracket w$  be the subterm. This is a well-tagged term (remark 8.14(3)) therefore there is an integer  $m$  such that  $\mathcal{H}(t', m)$ . The definition of  $\mathcal{H}$  implies that  $m = i$  and  $\mathcal{B}(\llbracket k/v, l \rrbracket w, i)$ . The definition of  $\mathcal{B}$  implies  $k \leq i$ .
- 2 Let  $t' = \llbracket i/u, j \rrbracket \llbracket k/v, l \rrbracket w$  be the subterm. There is an integer  $m$  such that  $\mathcal{H}(t', m)$ . Since  $\llbracket k/v, l \rrbracket w \notin \Lambda_{ws}$ , we have  $m \geq i + j$  and  $\mathcal{H}(\llbracket k/v, l \rrbracket w, m - j + 1)$ , and thus  $k = m - j + 1$ . Finally,  $k = m - j + 1 > i$ .

□

**Proposition 8.16.**  $WT$  is closed by  $\lambda_{ws}^\circ$ -reduction.

*Proof.* The proof is not difficult but tedious. We first prove that if  $t \rightarrow_{\lambda_{ws}} u$  and  $\mathcal{B}(t, m)$  then  $\mathcal{B}(u, m)$ . We may assume that the reduction is at the root of  $t$ . We consider each rule of the  $\lambda_{ws}$ -calculus. The proposition is a consequence of the fact that if  $t \rightarrow_{\lambda_{ws}^\circ} u$  and  $\mathcal{H}(t, m)$  then  $\mathcal{H}(u, m)$ . This is proved by induction on  $t$  using the previous fact. Again we may assume that the reduction is at the root, and we consider each rule of the  $\lambda_{ws}^\circ$ -calculus. The complete proof is given in the annex of (Guillaume, 1999b). □

**Lemma 8.17.** The  $\diamond$ -calculus is confluent and strongly normalizable on the set of well-tagged terms. Let  $\diamond(t)$  denote the normal form of  $t$  for the  $\diamond$ -calculus.

*Proof.* The  $\diamond$ -calculus is locally confluent because it has no critical pairs. The strong normalization of the  $\diamond$ -calculus is a trivial consequence of the strong normalization of the  $ws$ -calculus. □

**Proposition 8.18.** Let  $t$  be a well-tagged term. Then  $\diamond(t) \in \Lambda_{ws}$ .

*Proof.* If  $t$  is a well-tagged term then  $\diamond(t)$  also is one (proposition 8.16). If  $\diamond(t) \notin \Lambda_{ws}$  then it contains a tagged substitution and the lemma 8.15(1) ensures that we can move down this substitution. This contradicts the fact that  $\diamond(t)$  is a  $\diamond$ -normal form. □

### 8.3.3. The projection

We show that an infinite  $\lambda_{ws}^\circ$ -reduction of a well-tagged term  $t$ , gives an infinite  $\lambda_{ws}$ -reduction of  $\diamond(t)$ . This is done by showing that the relations  $R_1$  and  $R_2$  defined below satisfy the hypothesis of the projection lemma (lemma 2.7).

- $R_1$ : the  $\diamond$ -reductions and the reductions inside tagged substitutions (i.e.  $\llbracket i/u, j \rrbracket t \rightarrow \llbracket i/u', j \rrbracket t$  with  $u \rightarrow_{\lambda_{ws}} u'$ ).

—  $R_2$ : the other reductions, i.e. the  $\lambda_{ws}$ -rules used outside a tagged substitution.

**Lemma 8.19.**  $WT \subset SN(R_1)$ .

*Proof.* The measure  $\|\cdot\|$  is defined on well-tagged terms as follows.  $\lg(u)$  denotes the length of the longest  $\lambda_{ws}$ -derivation of  $u$  (which exists since any term inside a tagged substitution is strongly normalizable). Note that this measure is not the same as the one in proposition 5.12.

- $\|\underline{n}\| = 0$
- $\|\lambda t\| = \|t\|$
- $\|(t\ u)\| = \|t\| + \|u\|$
- $\|\langle k \rangle t\| = \|t\|$
- $\|[i/u, j]t\| = \|t\| + \|u\|$
- $\|\llbracket i/u, j \rrbracket t\| = \text{cxy}(t)(1 + \lg(u))$

We have to show that if  $t \rightarrow_{\diamond} u$  then  $\|t\| > \|u\|$ . By induction on  $t$ , we may assume that the reduction is at the root. For the rules  $e_{1\diamond}$ ,  $n_{1\diamond}$ ,  $n_{2\diamond}$  and  $n_{3\diamond}$ , note that if a term has no tagged substitution its measure is 0. For the other rules, the verification is immediate.

We also have to show that the measure decreases by reduction inside tagged substitutions. By induction on  $t$ , we may assume that the reduction is  $\llbracket i/u, j \rrbracket t \rightarrow \llbracket i/u', j \rrbracket t$  with  $u \rightarrow_{\lambda_{ws}} u'$ . We have  $\lg(u') < \lg(u)$  hence (since  $\text{cxy}(t) \geq 1$ ):

$$\|\llbracket i/u, j \rrbracket t\| = \text{cxy}(t)(1 + \lg(u)) > \text{cxy}(t)(1 + \lg(u')) = \|\llbracket i/u', j \rrbracket t\|.$$

□

**Lemma 8.20.** Let  $t$  be a well-tagged term. If  $t \rightarrow_{R_1} u$  then  $\diamond(t) \rightarrow_{\lambda_{ws}}^* \diamond(u)$ .

$$\begin{array}{ccc} t & \xrightarrow{\quad} & u \\ \downarrow \diamond & & \downarrow \diamond \\ \diamond(t) & \xrightarrow[\lambda_{ws}]{\quad \quad \quad}^* & \diamond(u) \end{array}$$

*Proof.* If the reduction  $t \rightarrow_{R_1} u$  is a  $\diamond$ -reduction then, by uniqueness of the  $\diamond$ -normal form,  $\diamond(t) = \diamond(u)$ .

If the reduction is inside a tagged substitution, we use induction on  $t$ . The difficult case is  $t = \llbracket i/v, j \rrbracket w$  and  $u = \llbracket i/v', j \rrbracket w$  with  $v \rightarrow_{\lambda_{ws}} v'$ . An induction on  $w$  gives  $\diamond(t) \rightarrow_{\lambda_{ws}}^* \diamond(u)$ . □

**Lemma 8.21.** Let  $t$  be a well-tagged term. If  $t \rightarrow_{R_2} u$  then  $\diamond(t) \rightarrow_{\lambda_{ws}}^+ \diamond(u)$ .

$$\begin{array}{ccc} t & \xrightarrow{\quad} & u \\ \downarrow \diamond & & \downarrow \diamond \\ \diamond(t) & \xrightarrow[\lambda_{ws}]{\quad \quad \quad}^+ & \diamond(u) \end{array}$$

*Proof.* This proof, by induction on  $t$ , is easy but tedious. The difficult case is  $t =$

$\llbracket i/v, j \rrbracket w$  and  $u = \llbracket i/v, j \rrbracket w'$  with  $w \rightarrow_{R_2} w'$ . By an induction on  $w$  we may assume that the reduction is at the root of  $w$ . We then have to consider each rule of  $\lambda_{ws}$ -calculus. This proof has been checked by a Caml Program and is given in the annex of (Guillaume, 1999b).  $\square$

**Proposition 8.22.** Let  $t \in \Lambda_{ws}^\diamond$  be a well-tagged term. If  $t$  has an infinite  $\lambda_{ws}^\diamond$ -reduction then  $\diamond(t)$  has an infinite  $\lambda_{ws}$ -reduction.

*Proof.* The previous lemmas prove the hypothesis of the projection lemma.  $\square$

We are now ready to finish the proof of the main result of this subsection.

*Proof of lemma 8.8* Let  $t = B \llbracket 0/w, l \rrbracket v$  with  $v, w \in NF(p)$ . Assume that  $v, w$  and the arguments of  $B$  are  $\lambda_{ws}$ -strongly normalizable but  $t$  is not strongly normalizable. Let  $t \rightarrow t_1 \rightarrow t_2 \rightarrow \dots$  be an infinite reduction of  $t$  and let  $t'_i$  be  $t_i$  where the residue of  $\llbracket 0/w, l \rrbracket$  has been tagged.

- $t' = B \llbracket 0/w, l \rrbracket v$  is a well-tagged term: by induction on  $B$ , we prove that  $\mathcal{H}(t', |B|)$  (cf. definitions 8.6 and 8.12)
  - If  $B = \llbracket \cdot \rrbracket$ ,  $t' = \llbracket 0/w, l \rrbracket v$  and  $w \in SN(\lambda_{ws})$ . Moreover  $v \in NF(p)$ . By remark 8.14(1), we have  $\mathcal{B}(v, 0)$ . Finally  $\mathcal{H}(t', 0)$ .
  - if  $B = \langle k \rangle B'$ : by the induction hypothesis  $\mathcal{H}(B' \llbracket 0/w, l \rrbracket v, |B'|)$  and so  $\mathcal{H}(\langle k \rangle B' \llbracket 0/w, l \rrbracket v, |B'| + k)$ , i.e.  $\mathcal{H}(t', |B|)$ .
  - If  $B = (B'w')$  with  $w' \in \Lambda_{ws}$ : by induction,  $\mathcal{H}(B' \llbracket 0/w, l \rrbracket v, |B'|)$ . The remark 8.14(2) gives  $\mathcal{H}(w', |B|)$ . Finally,  $\mathcal{H}(t', |B|)$ .
- $t' \rightarrow t'_1 \rightarrow t'_2 \rightarrow \dots$  is an infinite  $\lambda_{ws}^\diamond$ -reduction of  $t'$ : proposition 8.16 and lemma 8.15 that each  $t'_i$  is well-tagged and that the reduction  $t'_i \rightarrow t'_{i+1}$  is always possible (no  $c'_{1\diamond}$  or  $c'_{2\diamond}$  redex), respectively.
  - the proposition 8.16 ensures that each  $t'_i$  is well-tagged and lemma 8.15 ensures that the reduction  $t'_i \rightarrow t'_{i+1}$  is always possible (no  $c'_{1\diamond}$  or  $c'_{2\diamond}$  redex).
- $\diamond(t') = p(t)$ :  $t'$  has no untagged substitutions. The reduction from  $t$  to  $p(t)$  can be translated into a reduction from  $t'$  to  $\diamond(t')$  by using rules  $l_\diamond, a_\diamond, e_\diamond$  and  $n_\diamond$  instead of  $l, a, e$  and  $n$ . Thus  $\diamond(t')$  and  $p(t)$  differ only by the character of their substitutions (tagged or not). Since they have no substitutions,  $\diamond(t') = p(t)$ .
- $p(t)$  has an infinite reduction.  $t'$  is well-tagged and has an infinite  $\lambda_{ws}^\diamond$ -reduction. Proposition 8.22 gives an infinite  $\lambda_{ws}$ -reduction of  $\diamond(t') = p(t)$ .  $\square$

#### 8.4. Proof of the key lemma

The proof of the key lemma finishes the proof of theorem 8.1:

**Lemma 8.2** Let  $t \in NF(p) \setminus SN(\lambda_{ws})$ . There is  $u \in NF(p)$  such that  $u \notin SN(\lambda_{ws})$  and  $m(t) \rightarrow_{\lambda_w} m(u)$ .

*Proof.* We prove, by induction on  $t$ , that there is a term  $u$  such that:

- $u \notin SN(\lambda_{ws})$ ,

— there are  $t', t'' \in \Lambda_{w_s}$  such that  $t \rightarrow_m^* t' \rightarrow_b t''$  and  $u = p(t'')$ .

The result follows then immediately from lemma 8.7.

1) If  $t$  has a proper subterm  $v$  which is not  $\lambda_{w_s}$ -strongly normalizing then  $t = C\{v\}$  and there is a term  $w \notin SN(\lambda_{w_s})$  such that  $w = p(v')$  and  $v \rightarrow_m^* v' \rightarrow_b v''$ . Let  $u = C\{w\}$ . Since  $C$  has no substitutions,  $p(u) = C\{p(w)\}$ .

2) Else, Every proper subterm of  $t$  is  $\lambda_{w_s}$ -strongly normalizable. Let  $t = F\{B\{H\}\}$ .  $F$  is empty since (if not,  $B\{H\}$  would be a non  $\lambda_{w_s}$ -strongly normalizable proper subterm of  $t$ ).  $H$  is not a de Bruijn index since, otherwise,  $t$  would be strongly normalizable. Thus  $t = B\{(\langle k_1 \rangle \dots \langle k_n \rangle \lambda v w)\}$ . Let  $k = \sum_{i=0}^n k_i$  and

$$t' = B\{(\langle k \rangle \lambda v w)\} \quad t'' = B\{[0/w, k]v\} \quad u = p(B\{[0/w, k]v\})$$

By construction:  $t \rightarrow_m^* t' \rightarrow_b t''$  and  $u = p(t'')$ . It remains to prove that  $u$  has an infinite  $\lambda_{w_s}$ -reduction.

Since every subterm is strongly normalizable, any infinite reduction of  $t$  must reduce the head redex. The infinite reduction of  $t$  looks like:

$$t \rightarrow^* B'\{(\langle k \rangle \lambda v' w')\} \rightarrow B'\{[0/w', k]v'\} \rightarrow \dots$$

And thus  $t''$  has an infinite reduction:

$$t'' = B\{[0/w, k]v\} \rightarrow^* B'\{[0/w', k]v'\} \rightarrow \dots$$

Lemma 8.8 ensures that  $u = p(t'')$  has an infinite reduction. □

## 9. Conclusion

The counter-examples to the preservation of strong normalization of the  $\lambda\sigma$ -calculus and the  $\lambda s_e$ -calculus led us to introduce the  $\lambda_w$ -calculus: a new presentation of the  $\beta$ -reduction.

We then derived a calculus with explicit substitutions satisfying: step by step simulation of  $\beta$ , confluence on terms with metavariables and preservation of strong normalization.

The simulation property of our calculus is not exactly the expected one, however, we believe that the idea of keeping updating functions in terms rather than pushing them down is one of the interesting points of our calculus.

This calculus is the first (together with *SKInT* of Goubault and Goguen) to answer positively the open question on the existence of such a calculus. We believe that the link of our calculus with De Bruijn calculus is much simpler than the one of the *SKInT*-calculus.

We leave for future work the study of other systems of types for the  $\lambda_{w_s}$ -calculus. The implementation of this calculus would also be interesting in order to measure the efficiency of the use of labels.

## Acknowledgements

We would like to thank Pierre-Louis Curien, Délia Kesner, Yves Lafont and the anonymous referees for their helpful comments on this work.
