RIGOROUS DERIVATION OF THE KURAMOTO-SIVASHINSKY EQUATION IN A 2D WEAKLY NONLINEAR STEFAN PROBLEM.

CLAUDE-MICHEL BRAUNER, JOSEPHUS HULSHOF, AND LUCA LORENZI†

Abstract. In this paper we are interested in a rigorous derivation of the Kuramoto-Sivashinsky equation (K–S) in a Free Boundary Problem. As a paradigm, we consider a two-dimensional Stefan problem in a strip, a simplified version of a solid-liquid interface model. Near the instability threshold, we introduce a small parameter \( \varepsilon \) and define rescaled variables accordingly. At fixed \( \varepsilon \), our method is based on: definition of a suitable linear 1D operator, projection with respect to the longitudinal coordinate only, Lyapunov-Schmidt method. As a solvability condition, we derive a self-consistent parabolic equation for the front. We prove that, starting from the same configuration, the latter remains close to the solution of K–S on a fixed time interval, uniformly in \( \varepsilon \) sufficiently small.

1. Introduction

A very challenging problem in Free Boundary Problems is the derivation of a single equation for the interface or moving front which captures the dynamics of the system, at least asymptotically, when a suitable parameter \( \varepsilon \) tends to 0. This program has been formally achieved by Sivashinsky in the pioneering paper [11] within the context of Near-Equidiffusional Flames (NEF) in combustion theory (see [10]). Near the instability threshold, achieved at the critical value \( \alpha = 1 \) (\( \alpha \) reflects the physico-chemical characteristics of the combustible), the dispersion relation between the wave number \( k \) and the growth rate \( \omega_k \) reads:

\[
\omega_k = (\alpha - 1) k^2 - 4 k^4,
\]

and its counterpart in the physical coordinates is the Kuramoto-Sivashinsky equation

\[
\Phi_\tau + \nu \Phi_{\eta \eta \eta \eta} + \Phi_{\eta \eta} + \frac{1}{2} (\Phi_\eta)^2 = 0
\]  

(1.1)

(with \( \nu = 4 \)), a kind of modulation equation in the rescaled independent variables \( \tau = t \varepsilon^2 \) and \( \eta = y \sqrt{\varepsilon} \), when the small parameter \( \varepsilon = \alpha - 1 \) tends to 0. The Kuramoto-Sivashinsky equation, that we abbreviate hereafter as the K–S equation, or simply K–S, appears in a variety of domains in physics and chemistry, where it models cellular instabilities, pattern formation, turbulence phenomena and transition to chaos, see (among many other references) [8, 13] and the bibliography therein. There are many heuristic derivations of the K–S equation in the literature.
Our purpose here is to provide some rigorous mathematical commentary on the derivation of this well-known model.

As one would surmise at the outset, the K–S model comprises a balance between several effects. Roughly speaking, K–S arises when the competing effects of a destabilizing linear part and a stabilizing nonlinearity are the dominant processes in physical reality. The linear instability is itself the result of a competition between two linear operators, $A = D_{\eta \eta}$ and $\nu A^2$ (we call $\nu A^2 + A$ the Kuramoto-Sivashinsky linear operator).

Put another way, the K–S equation is the simplest, and indeed a paradigm system in which these effects compete equally. It is this dominant balance that is explored rigorously in the present essay. It will turn out that in deriving K–S as an asymptotic limit of more complex systems, only certain type of terms contribute to the lowest order of approximation. Other types of terms will lead to higher order perturbations. In a forthcoming paper, we intend to consider the effects of these higher order perturbations on the basic K–S system.

As a paradigm two-dimensional problem (see [3, 2, 1] for the one-dimensional case and the Q–S equation in flame front dynamics), we consider a solid-liquid interface model introduced by Frankel in [6]. The solidification front is represented by $x = \xi(t, y)$. The liquid phase occurs when $x < \xi(t, y)$, the solid one when $x > \xi(t, y)$. The dynamics of heat is described by the heat conduction equation

$$T_t(t, x, y) = \Delta T(t, x, y), \quad x \neq \xi(t, y),$$

(1.2)

where $y \in [-\ell/2, \ell/2]$ with periodic boundary conditions. At $-\infty$, the temperature of the liquid is normalized to 0. At the front $x = \xi(t, y)$ there are two conditions. First, the balance of energy at the interface is given by the jump

$$\left[ \frac{\partial T}{\partial n} \right] = V_n,$$

(1.3)

where $V_n$ is the normal velocity. Second, according to the Gibbs-Thompson law, the non-equilibrium interface temperature is defined by

$$T = 1 - \gamma \kappa + r(V_n),$$

(1.4)

where the melting temperature has been normalized to 1, $\kappa$ is the interface curvature and the positive constant $\gamma$ represents the solid-liquid surface tension. The function $r$ is increasing and such that $r(-1) = 0$, $r'(-1) = 1$, see [6]. Hereafter, we assume that $r - 1$ is linear and we replace the curvature by the second order derivative. Therefore, (1.4) becomes:

$$T = 1 - \gamma \xi_{yy} + V_n + 1.$$

(1.5)

It is no difficult to see that System (1.2), (1.3), (1.4) admits a one-phase planar travelling wave (TW) solution $\hat{T}$, which satisfies

$$\hat{T}_x = \hat{T}_{xx}, \quad x \neq 0.$$  

At the front $x = 0$,

$$\left[ \hat{T}_x \right] = -1, \quad \hat{T} = 1.$$  

Hence, $\hat{T}(x) = e^x$ for $x < 0$, and $\hat{T}(x) = 1$ for $x > 0$.

As usual, we fix the free boundary. We set $\xi(t, y) = -t + \varphi(t, y)$, $x' = x - \xi(t, y)$ and we will omit primes. In this new framework, (1.2) reads:

$$T_t + (1 - \varphi_T)T_x = \Delta \varphi T, \quad x \neq 0,$$
where $\Delta \varphi = (1 + (\varphi_y)^2)D_{xx} + D_{yy} - \varphi_y D_x - 2\varphi_y D_{xy}$. The front is now fixed at $x = 0$. The first condition (1.3) reads:

$$\varphi_t = 1 + (1 + (\varphi_y)^2) [T_x], \quad (1.6)$$

where we replace (1.5) by

$$T = 1 - \gamma \varphi_{yy} + \varphi_t + \frac{1}{2}(\varphi_y)^2.$$

Introducing the temperature perturbation $u = T - \hat{T}$, the problem for the couple $(u, \varphi)$ reads:

$$u_t + (1 - \varphi_t)u_x - \Delta \varphi u - \varphi_t \hat{T}_x = (\Delta \varphi - \Delta) \hat{T}, \quad x \neq 0, \quad (1.7)$$

where

$$(\Delta \varphi - \Delta) \hat{T} = \{(\varphi_y)^2 - \varphi_{yy}\} e^{x \chi_{(-\infty,0)}} = ((\varphi_y)^2 - \varphi_{yy}) \hat{T}_x.$$ 

As in [4], we make further simplifications: (i) we consider a quasi-steady problem, dropping the time derivative $u_t$ in (1.7); (ii) we take a linearized problem for $u$; (iii) we limit ourselves to considering only the second order term in the jump conditions at $x = 0$. Actually, as it has been observed in similar problems (see [3]), not far from the instability threshold the time derivative in the temperature equation has a relatively small effect on the solution. Our final system reads:

$$u_x - \Delta u - \varphi_t \hat{T}_x = (\Delta \varphi - \Delta) \hat{T}, \quad x \neq 0, \quad (1.8)$$

$$\varphi_t = [u_x] - (\varphi_y)^2, \quad (1.9)$$

$$u|_{x=0} = -\gamma \varphi_{yy} + \varphi_t + \frac{1}{2}(\varphi_y)^2. \quad (1.10)$$

For the convenience of the reader, we recall the main results of [4], where we considered Problem (1.8)-(1.10) in the strip $\mathbb{R} \times [-\ell/2, \ell/2]$, with periodic boundary conditions prescribed at $y = \pm \ell/2$. More precisely, we studied the stability of the TW solution and proved the following result: there exists $\gamma_c < 1$ such that

(i) for $\gamma > \gamma_c$, the TW solution to Problem (1.8)-(1.10) is orbitally stable (with asymptotic phase);

(ii) for $0 < \gamma < \gamma_c$, the TW is unstable.

We also showed that $\gamma_c = 1 - 3\lambda_1(\ell) + \cdots$, where $-\lambda_1(\ell) = -4\pi^2/\ell^2$ is the largest eigenvalue of the realization of $D_{yy}$ in $C([-\ell/2, \ell/2])$ with periodic boundary conditions and zero average.

The main tool is the derivation of a self-consistent equation for the front $\varphi$:

$$\varphi_t + G((\varphi_y)^2) = \Omega \varphi, \quad |y| \leq \frac{\ell}{2}, \quad (1.11)$$

where both $\Omega$ and $G$ are linear pseudo-differential operators whose symbols $\omega_k$ and $g_k$ are explicit and $g_0 = \frac{1}{2}$. Hence, at the zeroth order $G((\varphi_y)^2)$ coincides with the quadratic term of K–S. If we think formally of (1.11) in the whole space (i.e. $\ell = +\infty$), then $\omega_k$ is the growth rate which expands, for small wave number $k$, as

$$\omega(k) = (1 - \gamma)k^2 + (\gamma - 4)k^4 + \cdots,$$

with exchange of stability at $\gamma = 1$. Therefore, when $\gamma$ is close to unity, but smaller, it is natural to introduce a small parameter $\varepsilon > 0$, setting:

$$\gamma = 1 - \varepsilon,$$
and define the rescaled dependent and independent variables accordingly:

\[ t = \tau / \varepsilon^2, \quad y = \eta / \sqrt{\varepsilon}, \quad u = \varepsilon^2 v, \quad \varphi = \varepsilon \psi. \]  

(1.12)

Then we anticipate, in the limit \( \varepsilon \to 0 \), that \( \psi \simeq \Phi \), where \( \Phi \) solves the following K–S equation (with \( \nu = 3 \)):

\[ \Phi_t + 3\Phi_{yyyy} + \Phi_{yy} + \frac{1}{2}(\Phi_y)^2 = 0. \]  

(1.13)

This is what we have to establish in a rigorous mathematical way. Let us fix \( \ell_0 > 0 \). The main idea is to link the small parameter \( \varepsilon \) and the width of the strip, which will become larger and larger as \( \varepsilon \to 0 \), i.e., as \( \gamma \to 1 \). Take for \( \ell \):

\[ \ell_\varepsilon = \ell_0 / \sqrt{\varepsilon}, \]

which blows up as \( \varepsilon \to 0 \) and the strip \( \mathbb{R} \times [-\ell_\varepsilon / 2, \ell_\varepsilon / 2] \) approaches \( \mathbb{R}^2 \). We easily see that \( \lambda_1(\ell_\varepsilon) = 4\pi^2 / \ell_\varepsilon^2 = 4\pi^2 \varepsilon / \ell_0^2 \); hence,

\[ \gamma_c = 1 - \frac{12\pi^2}{\ell_0^2} \varepsilon + \ldots \]

Thus, \( \ell_\varepsilon \) becomes the new bifurcation parameter. We shall assume that \( \ell_0 > \sqrt{12} \pi \), in order to have \( \gamma_c \in (1 - \varepsilon, 1) \), i.e., \( \gamma > \gamma_c \), otherwise the TW is stable and the dynamics is trivial. Clearly, this is related to the stability of the null solution to K–S. The relevant eigenvalue of the Kuramoto-Sivashinsky linear operator \( 3A^2 + A \) is \( 3\lambda_1(\ell_0)^2 - \lambda_1(\ell_0) \) which vanishes for \( \lambda_1(\ell_0) = 1/3 \), i.e., when \( \ell_0 = \sqrt{12} \pi \).

An important feature of this paper is that we work in the fixed strip \( \mathbb{R} \times [-\ell_0 / 2, \ell_0 / 2] \), with the rescaled variables (1.12). We will return to the original variable only in the final section.

The main result is the following.

**Main Theorem.** Let \( \Phi_0 \in C^{6+2\alpha}([-\ell_0 / 2, \ell_0 / 2]) \), for some \( \alpha \in (0,1/2) \), satisfy \( D_k^{(k)} \Phi_0(-\ell_0 / 2) = D_k^{(k)} \Phi_0(\ell_0 / 2) \) for any \( k = 0, \ldots, 6 \). Let \( \Phi \) be the periodic solution of (1.13) (with period \( \ell_0 \)) on a fixed time interval \([0,T]\), satisfying the initial condition \( \Phi(0,) = \Phi_0 \). Then, there exists \( \varepsilon_0 = \varepsilon_0(T) \in (0,1/2) \) such that, for \( 0 < \varepsilon \leq \varepsilon_0 \), Problem (1.8)–(1.11) admits a unique smooth solution \((u, \varphi)\) on \([0,T/\varepsilon^2]\), which is periodic with period \( \ell_0 / \sqrt{\varepsilon} \) with respect to \( y \), and satisfies

\[ \varphi(0,y) = \varepsilon \Phi_0(y \sqrt{\varepsilon}), \quad |y| \leq \frac{\ell_0}{2\sqrt{\varepsilon}}. \]

Moreover, there exists a positive constant \( C \), independent of \( \varepsilon \in (0,\varepsilon_0] \), such that

\[ |\varphi(t,y) - \varepsilon \Phi(t\varepsilon^2, y \sqrt{\varepsilon})| \leq C \varepsilon^2, \quad 0 \leq t \leq \frac{T}{\varepsilon^2}, \quad |y| \leq \frac{\ell_0}{2\sqrt{\varepsilon}}. \]

For a precise definition of what smooth solution means we refer the reader to Section 3.

Clearly, the initial condition for \( \varphi \) is of special type, compatible with \( \Phi_0 \) and (1.1) at \( \tau = 0 \). Initial conditions of this type have been already considered in (1.3).

The paper is organized as follows. In Section 2 we introduce some notation and the function spaces we extensively use throughout the paper. In Section 3 we proceed to a formal Ansatz in the spirit of (1.1). We set \( \gamma = 1 - \varepsilon \), split \( v = v^0 + \varepsilon v^1 + \ldots \), \( \psi = \psi^0 + \varepsilon \psi^1 + \ldots \), and show that \( \psi^0 \) verifies the K–S equation (1.13), thanks to an elementary solvability condition. The paper consists in giving a rigorous proof of the Ansatz (i.e., to prove the main theorem), thanks to an
abstract solvability condition within the framework of adequate function spaces. In this respect, in Section 4 we transform System (1.8)-(1.10) in an equivalent problem (for the new unknowns) using the techniques of [4], which are based on

(i) definition of a suitable linear one-dimensional operator;
(ii) projection with respect to the \( x \) coordinate only;
(iii) Lyapunov-Schmidt method.

This allows us to decouple the system into a self-consistent fourth order (in space) parabolic equation for the front \( \psi \) and an elliptic equation which can be easily solved whenever a solution to the front equation is determined. Hence, the rest of the paper is devoted to study the parabolic equation. In this respect, according to the Ansatz, we split \( \psi = \Phi + \varepsilon \rho \). In Section 5, we solve the fourth order equation for \( \rho \), locally in time, with time domain possibly depending on \( \varepsilon \). Then, in Section 6, we prove that, for any \( T > 0 \), the function \( \rho \) exists, and is smooth, in the whole of \([0, T]\) provided \( \varepsilon \) is small enough. This result is obtained as a consequence of some \textit{a priori estimates} independent of \( \varepsilon \), which we prove in Subsection 5. The \textit{a priori estimates} are also used to prove the main theorem (see Subsection 6.3). Finally, some technical tools are deferred to the appendix.

2. Notation and function spaces

In this section we introduce some notation and the function spaces which will be used throughout the paper.

2.1. Notation. We denote by \( I, I_- \) and \( I_+ \), respectively, the sets

\[
I = \mathbb{R} \times [-\ell_0/2, \ell_0/2],
I_- = (-\infty, 0] \times [-\ell_0/2, \ell_0/2],
I_+ = [0, +\infty) \times [-\ell_0/2, \ell_0/2].
\]

We use the bold notation to denote the elements of both the spaces \( C((-\infty, 0]) \times C([0, +\infty)) \) and \( C(I_-) \times C(I_+) \). Given an element \( u \) of the previous spaces we denote by \( u_1 \) and \( u_2 \) its components. Hence, \( u_1 \in C((-\infty, 0]) \) (resp. \( u_1 \in C(I_-) \)) and \( u_2 \in C([0, +\infty)) \) (resp. \( u_2 \in C(I_+) \)). We write \( D^{(i)}_x u \) (resp. \( D^{(i)}_y u \)) \((i = 1, 2, \ldots)\) to denote the (generalized) function whose components are \( D^{(i)}_x u_1 \) and \( D^{(i)}_y u_2 \) (resp. \( D^{(i)}_y u_1 \) and \( D^{(i)}_y u_2 \)).

We extensively use the (generalized) functions \( T, T', U \) and \( V \), which are defined by

\[
\begin{align*}
T_1(x) &= e^x, \quad x \leq 0, \\
T_2(x) &= 1, \quad x \geq 0, \\
T'_1(x) &= e^x, \quad x \leq 0, \\
T'_2(x) &= 0, \quad x \geq 0,
\end{align*}
\]

\[
\begin{align*}
U_1(x) &= \frac{1-x}{3} e^x, \quad x \leq 0, \\
U_2(x) &= \frac{1}{3}, \quad x \geq 0, \\
V_1(x) &= \left( 1 - \frac{2}{3} x + \frac{x^2}{6} \right) e^x, \quad x \leq 0, \\
V_2(x) &= 1 + \frac{x}{3}, \quad x \geq 0.
\end{align*}
\]

2.2. Function spaces. Here, we introduce the function spaces we use in the paper.
2.2.1. Spaces of one variable only. Let us fix \( \ell_0 > 0 \) and denote by \( \mathbb{L}^2 \) the space of all square integrable functions \( f \) defined in \((-\ell_0/2, \ell_0/2)\), endowed with the Euclidean norm

\[
\|w\|_2^2 = \int_{-\ell_0}^{\ell_0} w^2 \, d\eta.
\]

Given a real (or even complex valued function) \( f \in \mathbb{L}^2(-\ell_0/2, \ell_0/2) \), we denote by \( \hat{f}(k) \) its \( k \)-th Fourier coefficient, i.e., we write

\[
f(\eta) = \sum_{k=0}^{+\infty} \hat{f}(k) w_k(\eta), \quad \eta \in (-\ell_0/2, \ell_0/2),
\]

where \( \{w_k\} \) is a complete set of eigenfunctions of the operator

\[
A : D(A) = \mathbb{H}^2 \to \mathbb{L}^2, \quad Au = D_{\eta\eta} u, \quad u \in D(A),
\]

with \( \ell_0 \)-periodic boundary conditions, corresponding to the non-positive eigenvalues

\[
0, -\frac{4\pi^2}{\ell_0^2}, -\frac{4\pi^2}{\ell_0^2}, -\frac{16\pi^2}{\ell_0^2}, -\frac{16\pi^2}{\ell_0^2}, -\frac{36\pi^2}{\ell_0^2}, \ldots
\]

For notational convenience we label this sequence as

\[
0 = -\lambda_0 > -\lambda_1 > -\lambda_2 > -\lambda_3 = -\lambda_4 > \ldots
\]

For integer or arbitrary real \( s \) we denote by \( \mathbb{H}^s \) the usual Sobolev spaces of \( \ell_0 \)-periodic (generalized) functions, which we conveniently represent as

\[
\mathbb{H}^s = \left\{ w = \sum_{k=0}^{+\infty} a_k w_k : \sum_{k=0}^{+\infty} \lambda_k^s a_k^2 < +\infty \right\}, \tag{2.3}
\]

with the usual norm. Next, for any \( \beta \geq 0 \), we denote by \( \mathbb{C}^\beta \) the space of all functions \( f \in \mathbb{C}^\beta := \mathbb{C}^\beta([-\ell_0/2, \ell_0/2]) \) such that \( f^{(j)}(-\ell_0/2) = f^{(j)}(\ell_0/2) \) for any \( j = 0, \ldots, [\beta] \). The space \( \mathbb{C}^\beta \) is endowed with the Euclidean norm of \( \mathbb{C}^\beta([-\ell_0/2, \ell_0/2]) \).

2.2.2. Function spaces of two variables. Given \( h, k \in \mathbb{N} \cup \{0\} \), an interval \( J \subset \mathbb{R} \) and a (possibly unbounded) closed set \( K \subset \mathbb{R}^d \) (for some \( d \in \mathbb{N} \)), we denote by \( \mathbb{C}^{h,k}(J \times K) \), the set of functions \( f : J \times K \to \mathbb{R} \) which are \( h \)-times continuously differentiable in \( J \times K \) with respect to the first variable and \( k \)-times continuously differentiable in \( J \times K \) with respect to the second variable. When \( J \times K \) is a compact set, we endow the space \( \mathbb{C}^{h,k}(J \times K) \) with the norm

\[
\|f\|_{\mathbb{C}^{h,k}(J \times K)} = \sup_{s \in J} \|f(s, \cdot)\|_{\mathbb{C}^k(K)} + \sup_{z \in K} \|f(\cdot, z)\|_{\mathbb{C}^h(J)}, \tag{2.4}
\]

for any \( f \in \mathbb{C}^{h,k}(J \times K) \). Using \( \mathbb{C}^{0,0} \) we can extend the definition of the spaces \( \mathbb{C}^{h,k}(J \times K) \) to the case when \( h, k \notin \mathbb{N} \).

Next, we introduce the space \( \mathcal{X} \) defined by:

\[
\mathcal{X} = \left\{ f = (f_1, f_2) \in C(I_-) \times C(I_+) : \tilde{f}_1 \in C_b(I_-), \tilde{f}_2 \in C_b(I_+) \right\}, \tag{2.5}
\]

where “\( b \)” stands for bounded and the functions \( \tilde{f}_1 \) and \( \tilde{f}_2 \) are defined as follows:

\[
\tilde{f}_1(x, \eta) = e^{-\frac{\eta}{\ell_0}} f_1(x, \eta), \quad x \leq 0, \quad |\eta| \leq \frac{\ell_0}{2},
\]

\[
\tilde{f}_2(x, \eta) = e^{-\frac{\eta}{\ell_0}} f_2(x, \eta), \quad x \geq 0, \quad |\eta| \leq \frac{\ell_0}{2}.
\]
In the sequel, we will write \( \tilde{f} := (\tilde{f}_1, \tilde{f}_2) \). The space \( \mathcal{X} \) is a Banach space when endowed with the norm

\[
\|f\|_X = \|\tilde{f}_1\|_{C_b(I_-)} + \|\tilde{f}_2\|_{C_b(I_+)} := \sup_{(x,\eta) \in I_-} |\tilde{f}_1(x,\eta)| + \sup_{(x,\eta) \in I_+} |\tilde{f}_1(x,\eta)|,
\]

for any \( f \in \mathcal{X} \).

3. Formal Ansatz

Let us set \( \gamma = 1 - \varepsilon \) in (1.10). Applying the change of variables defined by (1.12) to Problem (1.8)-(1.10), the problem for the couple \((v, \psi)\) reads (after simplification by \( \varepsilon^2 \)) as follows:

\[
v_x - (v_{xx} + \varepsilon v_{\eta\eta}) = (\varepsilon \psi_\tau + \varepsilon (\psi_\eta^2 - \psi_{\eta\eta})) e^x \chi_0, \tag{3.1}
\]

and at \( x = 0 \):

\[
\varepsilon \psi_\tau = [v_x] - \varepsilon (\psi_\eta^2), \tag{3.2}
\]

\[
v_{x=0} = -\psi_{\eta\eta} + \varepsilon \psi_{\eta\eta} + \varepsilon (\psi_\tau + \frac{1}{2} (\psi_\eta)^2). \tag{3.3}
\]

In the spirit of [11, p. 75], we look for formal expansions:

\[
v = v^0 + \varepsilon v^1 + \ldots, \quad \psi = \psi^0 + \varepsilon \psi^1 + \ldots
\]

of the solution to Problem (3.1)–(3.3). Considering the zeroth order part of (3.1)–(3.3) (i.e., the terms with no powers of \( \varepsilon \) in front), it is easy to see that the function \( v^0 \) verifies the system

\[
v^0_x = \psi^0_{\eta\eta} e^x \chi_{(-\infty,0]}, \tag{3.4}
\]

\[
[v^0_x] = 0, \tag{3.5}
\]

\[
v^0_{x=0} = -\psi^0_{\eta\eta}. \tag{3.6}
\]

It is trivial to solve (3.4) together with e.g., (3.5): it gives

\[
v^0 = \begin{cases} 
-\psi^0_{\eta\eta} e^x (1 - x), & x \leq 0, \\
-\psi^0_{\eta\eta}, & x > 0.
\end{cases}
\]

We remark that (3.3) is automatically verified. Hence, we are unable to “close” the nonlinear system for \((v^0, \psi^0)\) at the zeroth order. This situation is quite common in singular perturbation theory when the zeroth order can not be fully determined, see e.g., [5]. In such a case, one needs to go to the first order, which is indeed linear. Most often, the latter demands a solvability condition, for example based on the Fredholm alternative, which provides the missing relation for the zeroth order. Therefore, repeating computations similar to the previous ones, we get the following system for \((v^1, \psi^1)\):

\[
v^1_x - v^1_{xx} - \psi^0_{\eta\eta} = \{ \psi^0_\tau + (\psi^0_\eta^2 - \psi^1_{\eta\eta}) e^x \chi_{(-\infty,0]} \}. \tag{3.7}
\]

At \( x = 0 \),

\[
[v^1_x] = \psi^1_\eta + (\psi^0_\eta)^2, \tag{3.8}
\]

\[
v^1_{x=0} = -\psi^1_{\eta\eta} + \psi^0_\eta + \psi^0_\tau + \frac{1}{2} (\psi^0_\eta)^2. \tag{3.9}
\]
Obviously,

\[ v^0_\eta = \begin{cases} 
-\psi^0_\eta e^x(1-x), & x \leq 0, \\
-\psi^0_\eta, & x > 0.
\end{cases} \]

Clearly, the solution to (3.7) is given by

\[ v_1 = \begin{cases} 
ae^x + 2\psi_{\eta\eta\eta} - \psi_r - (\psi_\eta)^2 + \psi_\eta xe^x - \frac{1}{2}\psi_{\eta\eta\eta}x^2e^x, & x \leq 0, \\
a - \psi_{\eta\eta\eta}, & x > 0,
\end{cases} \]

where \( a \) is an arbitrary parameter. There are two remaining unknowns at the first order, namely \( a \) and \( \psi_{\eta\eta} \), and still two relations at \( x = 0 \). First, we use (3.9), which gives:

\[ a = v^1(0) = -\psi^1_\eta + \psi^0_\eta + \psi^2_\eta + \frac{1}{2}(\psi^0_\eta)^2. \quad (3.10) \]

Second, we compute:

\[ v^1_k(0^+) = -\psi^0_{\eta\eta\eta} \]

and

\[ v^1_k(0^-) = a + 2\psi^0_{\eta\eta\eta} - \psi^0_r - (\psi^0_\eta)^2 + \psi^1_\eta. \]

Therefore, from (3.8) we get:

\[ v^1_k(0^+) - v^1_k(0^-) = -a - 3\psi^0_{\eta\eta\eta} - \psi^0_r - (\psi^0_\eta)^2 + \psi^1_\eta = \psi^0_r + (\psi^0_\eta)^2. \quad (3.11) \]

Obviously (3.10)-(3.11) is a linear system for \((a, \psi^1_\eta)\) with solvability condition:

\[ \psi^0_\eta + \psi^1_\eta - \frac{1}{2}(\psi^0_\eta)^2 + \psi^0_{\eta\eta\eta} = 0, \]

i.e., \( \psi^0 \) verifies a K–S equation.

4. AN EQUIVALENT PROBLEM TO (3.1)–(3.3)

The aim of this section consists in transforming Problem (3.1)–(3.3) into an equivalent one. More precisely, we are going to decouple the problem for \((v, \psi)\), getting a self-consistent equation for the front \( \psi \) and an equation for the other unknown (say \( z \)) which can be immediately solved once \( \psi \) is known.

In deriving the equivalent problem, we assume that the solution \((v, \psi)\) to Problem (3.1)–(3.3) in the time domain \([0, T]\) belongs to the space \( \mathcal{V}_T \times \mathcal{Y}_T \) where

**Definition 4.1.** For any \( T > 0 \), we denote by \( \mathcal{V}_T \) the space of all functions \( v : [0, T] \times \mathbb{R} \to \mathbb{R} \) such that

(i) \( v \) is twice continuously differentiable with respect to the spatial variable \( x \) in \([0, T] \times I_-\) and in \([0, T] \times I_+\);

(ii) the functions \((\tau, x, \eta) \mapsto e^{-\frac{\xi}{\ell_0}}D_x^{(i)}u(\tau, x, \eta)\) and \((\tau, x, \eta) \mapsto e^{-\frac{\xi}{\ell_0}}D_\eta^{(i)}u(\tau, x, \eta)\) are bounded in \([0, T] \times I_-\) and in \([0, T] \times I_+\) for any \( i = 1, 2, 3 \).

Further, for any \( \alpha \in (0, 1/2) \), we denote by \( \mathcal{Y}_T \) the space of all functions \( \zeta \in C^{1,\frac{1}{4}}([0, T] \times [-\ell_0/2, \ell_0/2]) \), such that \( \zeta_{\tau} \in C^{0,2+\alpha}([0, T] \times [-\ell_0/2, \ell_0/2]) \) and \( D_\eta^{(j)}(\cdot, -\ell_0/2) = D_\eta^{(j)}(\cdot, \ell_0/2) \) for \( j = 0, 1, 2, 3 \).

**Remark 4.2.** It is immediate to check that, if \( \zeta \in \mathcal{Y}_T \), then the function \( \psi_{\eta\eta} \) is continuously differentiable in \([0, T] \times [-\ell_0/2, \ell_0/2]\) with respect to \( \tau \) and, consequently, \( \psi_{\tau\eta\eta} = \psi_{\eta\eta\tau} \). Hence, in what follows, we always write \( \psi_{\tau\eta\eta} \) instead of \( \psi_{\eta\eta\tau} \).
4.1. Derivation of a self-consistent equation for the front. In this subsection we derive a self-consistent equation for the front. Since its derivation is rather long, we split the proof into several steps.

4.1.1. Elimination of $\psi_{\tau}$. First we eliminate $\psi_{\tau}$ in (3.1) thanks to (3.3), getting the equation

$$v_x - v_{xx} - \varepsilon v_{\eta\eta} - v(\cdot, 0, \cdot)\hat{T}_x = \left(\frac{1}{2}(\psi_\eta)^2 - \varepsilon \psi_{\eta\eta}\right)\hat{T}_x.$$  

(4.1)

Let us set $v(\tau, x, \eta) := (v(\tau, x, \eta)\chi_{(-\infty, 0)}(x), v(\tau, x, \eta)\chi_{[0, +\infty)}(x))$ and

$$F_0 = \left(\psi_\eta - \frac{1}{2}(\psi_\eta)^2\right)T', \quad g = \psi_\tau + (\psi_\eta)^2,$$

where $T'$ is given by (2.3). Taking (4.3) and (4.4) into account, one can easily show that the function $v$ solves the problem

$$\begin{cases}
\mathcal{L}v = \varepsilon F_0 - \varepsilon v_{\eta\eta}, \\
v_2(\cdot, 0, \cdot) - v_1(\cdot, 0, \cdot) = 0, \\
D_x v_2(\cdot, 0, \cdot) - D_x v_1(\cdot, 0, \cdot) = \varepsilon g,
\end{cases}$$

(4.2)

where

$$(\mathcal{L}v)(\cdot, x, \eta) = \begin{cases}
D_{xx} v_1(\cdot, x, \eta) - D_x v_1(\cdot, x, \eta) + \varepsilon^2 v_1(\cdot, 0, \eta), & x \leq 0, \quad |\eta| \leq \frac{\ell}{2}, \\
D_{xx} v_2(\cdot, x, \eta) - D_x v_2(\cdot, x, \eta), & x \geq 0, \quad |\eta| \leq \frac{\ell}{2}.
\end{cases}$$

4.1.2. Lifting up the boundary conditions. Now we are going to use the first part of (3.4). We introduce the new unknown $w = v - \varepsilon \mathcal{N}(g)$, where $\mathcal{N}(g) = g(V - T)$, and $V$ and $T$ are defined in (2.1) and (2.2). With a straightforward computation, we see that the function $w$ turns out to solve the problem

$$\begin{cases}
\mathcal{L}w = \varepsilon F_0 - \varepsilon w_{\eta\eta} - \varepsilon^2 g_{\eta\eta}\mathcal{N}(1) - \varepsilon g \mathcal{L}\mathcal{N}(1), \\
w_2(\cdot, 0, \cdot) - w_1(\cdot, 0, \cdot) = 0, \\
D_x w_2(\cdot, 0, \cdot) - D_x w_1(\cdot, 0, \cdot) = 0.
\end{cases}$$

(4.3)

Since $v \in \mathcal{Y}_T$, $v(\tau, \cdot) \in \mathcal{X}$ (see (2.3) for the definition of the space $\mathcal{X}$) for any $\tau \in [0, T]$, then a straightforward computation shows that the function $w(\tau, \cdot)$ belongs to $\mathcal{X}$ for any $\tau \in [0, T]$, and, hence, to the set

$$\left\{h \in C^{2, 0}(L_\tau) \times C^{2, 0}(I_\tau) : h, \mathcal{L}h \in \mathcal{X}, D_j^2 h_1(0, \cdot) = D_j^2 h_2(0, \cdot), j = 0, 1 \right\},$$

which is the domain of the realization $L$ of the operator $\mathcal{L}$ in $\mathcal{X}$, see Section A.1.

4.1.3. A Lyapunov-Schmidt method. From the results in the previous subsection, we know that $w(\tau, \cdot) \in D(L)$ for any $\tau \in [0, T]$, and it solves the equation

$$Lw = \varepsilon F_0 - \varepsilon w_{\eta\eta} - \varepsilon^2 g_{\eta\eta}\mathcal{N}(1) - \varepsilon g \mathcal{L}\mathcal{N}(1).$$

(4.4)

We are going to project (4.4) along a suitable subspace of $\mathcal{X}$, to derive a self-consistent equation for the front $\psi$.

As Theorem A.1 shows, the operator $L$ is sectorial in $\mathcal{X}$. Hence, it generates an analytic semigroup. Moreover, 0 is an isolated eigenvalue of $L$ and the spectral projection on the kernel of $L$ is the operator $\mathcal{P}$ defined by

$$\mathcal{P}(f) = \left(\int_{-\infty}^0 f_1(x, \cdot)dx + \int_0^{+\infty} e^{-x} f_2(x, \cdot)dx\right) U := Q(f)U, \quad f \in \mathcal{X},$$

where $Q(f)U$
From the very general theory of analytic semigroup, it follows that, for a given \( g \in X \), the equation \( Lz = g \) admits a solution \( z \in D(L) \) if and only if \( P(g) = 0 \).

Since \( w \) solves Equation (4.4), it follows that

\[
P(\varepsilon F_0 - \varepsilon w_{\eta\eta} - \varepsilon gL_aN(1) - \varepsilon^2 g_{\eta\eta}N(1)) = 0,
\]

or equivalently, after division by \( \varepsilon > 0 \),

\[
0 = Q(F_0 - w_{\eta\eta} - gL_aN(1) - \varepsilon g_{\eta\eta}N(1)).
\]  

(4.5)

Since

\[
Q(F_0) = \psi_{\eta\eta} - \frac{1}{2} (\psi_{\eta})^2,
\]  

(4.6a)

\[
Q(g_{\eta\eta}N(1)) = \frac{4}{3} \varepsilon \psi_{\tau \eta\eta} = \frac{4}{3} (\psi_{\tau \eta\eta} + ((\psi_{\eta})^2)_{\eta\eta}),
\]  

(4.6b)

\[
Q(gL_aN(1)) = -g = -\psi_{\tau} - (\psi_{\eta})^2,
\]  

(4.6c)

we can rewrite Equation (4.5) as follows:

\[
\psi_{\tau} - \frac{4}{3} \varepsilon \psi_{\tau \eta\eta} + \frac{1}{2} (\psi_{\eta})^2 + \psi_{\eta\eta} - \frac{4}{3} \varepsilon ((\psi_{\eta})^2)_{\eta\eta} = Q(w_{\eta\eta}).
\]  

(4.7)

To get a self-contained equation for the front \( \psi \), we have to give a representation of \( Q(w_{\eta\eta}) \) in the right-hand side of (4.7). For this purpose, in the spirit of the Lyapunov-Schmidt method, we split \( w(\tau, \cdot) (\tau \in [0, T]) \) along \( \mathcal{P}(X) \) and \( (I - \mathcal{P})(X) \). Writing

\[
w = aU + \varepsilon z,
\]

and observing that our assumptions on \( v \) guarantee that the function \( z_{\eta\eta} \) belongs to \( (I - \mathcal{P})(X) \), we get

\[
Q(w_{\eta\eta}) = Q(a_{\eta\eta}U + \varepsilon z_{\eta\eta}) = a_{\eta\eta}.
\]  

(4.8)

Let us compute \( a \) and its derivatives. We use the relation in (3.3) to obtain

\[
\frac{1}{3} \varepsilon \partial_t + \varepsilon \partial_{11}(\cdot, 0, \cdot) = (\varepsilon - 1) \psi_{\eta\eta} + \varepsilon \psi_{\tau} + \frac{1}{2} \varepsilon (\psi_{\eta})^2.
\]

Thus,

\[
a_{\eta\eta} = -3\varepsilon D_{\eta\eta} z_{1}(\cdot, 0, \cdot) + 3(\varepsilon - 1) \psi_{\eta\eta} + 3\varepsilon \psi_{\tau \eta\eta} + \frac{3}{2} \varepsilon ((\psi_{\eta})^2)_{\eta\eta}.
\]  

(4.9)

From (1.8) and (1.9), it follows that

\[
Q(w_{\eta\eta}) = -3\varepsilon D_{\eta\eta} z_{1}(\cdot, 0, \cdot) + 3(\varepsilon - 1) \psi_{\eta\eta} + 3\varepsilon \psi_{\tau \eta\eta} + \frac{3}{2} \varepsilon ((\psi_{\eta})^2)_{\eta\eta}.
\]

Replacing into (4.7) we get the following equation for \( \psi \):

\[
\psi_{\tau} - \frac{13}{13} \varepsilon \psi_{\tau \eta\eta} + 3(1 - \varepsilon) \psi_{\eta\eta} + \psi_{\eta\eta} + \frac{1}{2} (\psi_{\eta})^2 + 3\varepsilon D_{\eta\eta} z_{1}(\cdot, 0, \cdot) = \frac{17}{6} \varepsilon ((\psi_{\eta})^2)_{\eta\eta}.
\]  

(4.10)

We already see that (4.10) reduces to K–S if \( \varepsilon = 0 \). However, we still have \( z_1 \) in the right-hand side of (4.10). In the next subsection, we write it in terms of \( \psi \).
4.1.4. The equation for $z$. To write $D_{\eta\eta}z_1(\cdot,0,\cdot)$ in terms of the function $\psi$, we determine the equation satisfied by function $z$. Projecting Equation (4.4) along $(I-\mathcal{P})(\mathcal{L}\mathcal{N}(1))$, we see that the function $z(\tau,\cdot) = (I-\mathcal{P})z(\tau,\cdot) \in D(L) (\tau \in [0,T])$ solves the equation

$$Lz = (I-\mathcal{P})(F_0) - g(I-\mathcal{P})(\mathcal{L}\mathcal{N}(1)) - \varepsilon g_{\eta\eta}(I-\mathcal{P})(\mathcal{N}(1)) - \varepsilon z_{\eta\eta}.$$  

From (4.6a)-(4.6c) we obtain

$$\text{I.6a} - \text{I.6c}$$

so that we can rewrite Equation (4.11) as

$$Lz + \varepsilon z_{\eta\eta} = \left(\psi_{\eta\eta} - \frac{1}{2}(\psi_{\eta})^2\right)(T' - U),$$

$$g_{\eta\eta}(I-\mathcal{P})(\mathcal{N}(1)) = \left(\psi_{\eta\eta} + (\psi_{\eta})^2\right)(V - T - \frac{4}{3}U).$$

We now observe that the operator $L + \varepsilon A := L + \varepsilon D_{\eta\eta}$ with domain

$$D(L + \varepsilon A) = \{ u \in D(L) : u_{\eta\eta} \in \mathcal{X} \},$$

is closable and its closure, denoted by $L_z$, is sectorial and 0 is in the resolvent set of the restriction of $L_z$ to $(I-\mathcal{P})(\mathcal{X})$ (see Theorem A.2). Hence, we can invert (4.14) using $R(0,L_z) = (L_z)^{-1}$, collecting linear and nonlinear terms in $\psi$:

$$z = R(0,L_z) \left(-\psi_{\eta\eta}(T' - U) + \varepsilon \psi_{\eta\eta} \left(V - T - \frac{4}{3}U\right)\right)$$

$$+ R(0,L_z) \left\{ \frac{1}{2}(\psi_{\eta})^2(T' - U) + \varepsilon((\psi_{\eta})^2)_{\eta\eta} \left(V - T - \frac{4}{3}U\right) \right\}. \tag{4.14}$$

4.1.5. The fourth-order equation for the front. Using (4.14), we can compute $z_1(\cdot,0,\cdot)$ getting

$$z_1(\cdot,0,\cdot) = -\left(R(0,L_z) [\psi_{\eta\eta}(T' - U)]\right)(\cdot,0,\cdot)$$

$$+ \varepsilon \left(R(0,L_z) \left[ \psi_{\eta\eta} \left(V - T - \frac{4}{3}U\right)\right]\right)(\cdot,0,\cdot)$$

$$+ \left\{ R(0,L_z) \left( \frac{1}{2}(\psi_{\eta})^2(T' - U) + \varepsilon((\psi_{\eta})^2)_{\eta\eta} \left(V - T - \frac{4}{3}U\right) \right) \right\}(\cdot,0,\cdot).$$

Since $z_1$ is as smooth as $v_1$ is, we can differentiate the previous formula twice with respect to $\eta$ obtaining

$$D_{\eta\eta}z_1(\cdot,0,\cdot) = - (D_{\eta\eta}R(0,L_z) [\psi_{\eta\eta}(T' - U)]) (\cdot,0,\cdot)$$

$$+ \varepsilon \left(D_{\eta\eta}R(0,L_z) \left[ \psi_{\eta\eta} \left(V - T - \frac{4}{3}U\right)\right]\right)(\cdot,0,\cdot)$$

$$+ \frac{1}{2} \left\{ D_{\eta\eta}R(0,L_z) \left((\psi_{\eta})^2(T' - U))\right\}(\cdot,0,\cdot).$$
+ \varepsilon \left\{ D_{\eta\eta} R(0, L_\varepsilon) \left[ (\psi_\eta)^2 \eta \eta \left( V - T - \frac{4}{3} U \right) \right] \right\} (\cdot, 0, \cdot). \quad (4.15)

Estimate (A.2) and our assumptions on \( \psi \) (which guarantee that the function \( \psi_{\eta\eta} \) is continuously differentiable in \([0, T]\) with values in \( C^2(\tau, \eta, 0, 2, 0, 2) \), see Remark 4.2) show that the function \( (D_{\eta\eta} R(0, L_\varepsilon) \left[ \psi_{\eta\eta} \left( V - T - \frac{4}{3} U \right) \right] ) (\cdot, 0, \cdot) \) is continuously differentiable in \([0, T] \times [-\ell_0/2, \ell_0/2] \) with respect to \( \tau \) and its derivative equals the function \( (D_{\eta\eta} R(0, L_\varepsilon) \left[ \psi_{\tau\eta\eta} (V - T - \frac{4}{3} U) \right] ) (\cdot, 0, \cdot) \). Hence, replacing (4.1) into (4.11) and taking the above remark into account, we obtain that the function \( \psi \) eventually solves the fourth-order equation

\[
\frac{\partial}{\partial \tau} \mathcal{S}_\varepsilon \psi = \mathcal{S}_\varepsilon \psi + \mathcal{F}_\varepsilon ((\psi_\eta)^2),
\]

where

\[
\mathcal{S}_\varepsilon \psi = \psi - \frac{13\varepsilon}{3} \psi_{\eta\eta} + 3\varepsilon^2 \left( D_{\eta\eta} R(0, L_\varepsilon) \left[ \psi_{\eta\eta} \left( V - T - \frac{4}{3} U \right) \right] \right) (\cdot, 0, \cdot), \quad (4.17a)
\]

\[
\mathcal{S}_\varepsilon \psi = -3(1 - \varepsilon) \psi_{\eta\eta\eta\eta} - \psi_{\eta\eta} + 3\varepsilon \left( D_{\eta\eta} R(0, L_\varepsilon) \left[ \psi_{\eta\eta} (T' - U) \right] \right) (\cdot, 0, \cdot), \quad (4.17b)
\]

\[
\mathcal{F}_\varepsilon (\psi) = -3\varepsilon D_{\eta\eta} R(0, L_\varepsilon) \left( \frac{1}{2} \psi (T' - U) + \varepsilon \psi_{\eta\eta} \left( V - T - \frac{4}{3} U \right) \right) \left( \cdot, 0, \cdot \right)
+ \frac{17\varepsilon}{6} \psi_{\eta\eta} - \frac{1}{2} \psi. \quad (4.17c)
\]

Clearly, (4.16) reduces to K–S when we set \( \varepsilon = 0 \).

### 4.2. Equivalence between Problem (3.1)-(3.3) and Equation (4.16)

The following theorem states the equivalence of Problem (3.1)-(3.3) and Equation (4.16).

**Theorem 4.3.** Fix \( \varepsilon, T > 0 \) and \( \alpha \in (0, 1/2) \). Further, let \( (v, \psi) \in \mathcal{Y}_T \times \mathcal{Y}_T \) be a solution to Problem (3.1)-(3.3) (see Definition 4.1). Then, the function \( \psi \) turns out to solve Equation (4.16).

Vice versa, if \( \psi \in \mathcal{Y}_T \) is a solution to Equation (4.16), then there exists a function \( v \in \mathcal{Y}_T \) such that the pair \((v, \psi)\) solves the Cauchy problem (3.1)-(3.3).

**Proof.** In view of the arguments in Subsection 4.1, we just need to show that to any solution \( \psi \in \mathcal{Y}_T \) to Equation (4.16) there corresponds a unique function \( v \in \mathcal{Y}_T \) such that the pair \((v, \psi)\) solves Problem (3.1)-(3.3). For this purpose, let \( z \) be defined by (4.14). By assumptions, the functions \( \psi_{\eta\eta}, \psi_{\eta\eta\eta}, ((\psi_\eta)^2)_{\eta\eta} \) and \( \psi_{\tau\eta\eta} \) are bounded in \([0, T]\) with values in the space \( C^2_T \). Moreover, the functions \( T' - U \) and \( V - T - \frac{4}{3} U \) are in \((I - \mathcal{P})(\mathcal{X})\). Hence, we can apply Theorem A.2(iv) and conclude that \( z(\tau, \cdot) \) is in \( D(L + \varepsilon A) \) (see (1.13)) for any \( \tau \in [0, T] \).

Clearly, the components \( z_1 \) and \( z_2 \) of \( z \) are continuous in \([0, T] \times I_- \) and in \([0, T] \times I_+ \), respectively. Let us show that also the spatial derivatives (up to the second order) of the functions \( z_1 \) and \( z_2 \) are continuous in \([0, T] \times I_- \) and \([0, T] \times I_+ \).

This follows from the estimate (A.2) provided one shows that the functions \( \psi_{\eta\eta} \), \(((\psi_\eta)^2)_{\eta\eta} \) and \( \psi_{\tau\eta\eta} \) are continuous in \([0, T]\) with values in \( C^2_\theta \) for some \( \theta \in (0, \alpha) \). Such a property can be proved using an interpolation argument. Indeed, it is well-known that, for any \( \theta \in (0, \alpha) \), there exists a positive constant \( C \) such that

\[
\| \psi \|_{L^2([-\ell_0/2, \ell_0/2])} \leq C \| \psi \|_{L^2([-\ell_0/2, \ell_0/2])}^{1-\theta/\alpha} \| \psi \|_{C^{\alpha}([-\ell_0/2, \ell_0/2])}^{-\theta/\alpha}.
\]
for any $\psi \in C^\alpha([-\ell_0/2, \ell_0/2])$ (see e.g., [4]). Applying this estimate to the function $\psi_N(\tau_1, \cdot) - \psi_N(\tau_1, \cdot)$, with $\tau_1, \tau_2 \in [0, T]$, shows that $\psi_N$ is continuous in $[0, T]$ with values in $C^\alpha([\ell_0/2, \ell_0/2])$ (and, hence, in $C^\alpha_0$), for any $\theta \in (0, \alpha)$. The same argument shows that the functions $\psi_N^2, (\psi_N)^2$ and $\psi_N^3$ are bounded in $[0, T]$. Hence, the function $\psi_N$ is continuous in $[0, T]$ with values in $C^\alpha_0$ as well. Finally, since $z(\tau, \cdot)$ belongs to $D(L + \varepsilon A)$ for any $\tau \in [0, T]$, the functions $\psi(\tau, x, \eta) \mapsto e^{-\varepsilon \tau} D_N^i z_i(\tau, x, \eta)$ are bounded in $[0, T] \times I$ and in $[0, T] \times I_\pm$, respectively, for any $i = 0, 1, 2$.

The function $z$ will represent the component along $(I - \mathcal{P})\mathcal{Z}$ of the function $\psi - \varepsilon \mathcal{N}(\psi_T + (\psi_N)^2)$, where $\psi_1(\cdot, x, \cdot) = \psi(\cdot, x, \cdot)\chi_{(-\infty, 0]}(x)$, $\psi_2(\cdot, x, \cdot) = \psi(\cdot, x, \cdot)\chi_{[0, +\infty)}(x)$ and $v$ is the solution to Problem [1.3] we are looking for. The computations in Subsection [1.3] suggest to set $v := w + \varepsilon \mathcal{N}(\psi_T + (\psi_N)^2) := aU + \varepsilon x + \varepsilon \mathcal{N}(\psi_T + (\psi_N)^2)$, where

$$a = -3\varepsilon \psi_1(\cdot, 0, \cdot) + 3(\varepsilon - 1)\psi_N + 3\varepsilon \psi_T + \frac{3}{2} \psi_N^2.$$  \hfill (4.18)

Using Formulae (4.6a)-(4.6c) and (4.13) we can show that

$$\mathcal{L}v = L(aU) + \varepsilon LA + \varepsilon \mathcal{N}(\psi_T + (\psi_N)^2)$$

$$= (I - \mathcal{P})\{\varepsilon F_0 - \varepsilon w\psi_N - \varepsilon \mathcal{N}(\psi_T + (\psi_N)^2) - \varepsilon^2 \mathcal{N}((\psi_T + (\psi_N)^2))\psi_N\}$$

$$+ \varepsilon \mathcal{L}(\mathcal{N}(\psi_T + (\psi_N)^2))$$

$$= \varepsilon F_0 - \varepsilon w\psi_N - \varepsilon^2 \mathcal{N}((\psi_T + (\psi_N)^2))\psi_N$$

$$= \varepsilon F_0 - \varepsilon \psi_N.$$  \hfill (4.19)

Moreover, it is easy to check that $v$ satisfies also the boundary conditions of the Cauchy problem (1.2).

Clearly, the function $v$ defined above belongs to $\mathbb{H}\mathcal{T}$ and the pair $(v, \psi)$ solves the differential equation (1.3). Using the second boundary condition in (1.2), it follows immediately that $(v, \psi)$ satisfies condition (1.3). Finally, to check condition (1.3) it suffices to use (1.18), recalling that $\mathcal{N}(\psi_T + (\psi_N)^2)$ vanishes when $\eta = 0$. This completes the proof. $\square$

4.3. The equation for the remainder. In view of Theorem 4.4, in the rest of the paper we deal only with Equation (4.14) with periodic boundary conditions. To begin with, we recall the following result about K–S:

**Theorem 4.4.** Let $\Phi_0 \in C^{\alpha+k}$ for some $\alpha \in (0, 1/2)$. Then, the Cauchy problem

$$\begin{align*}
\Phi_\tau(\tau, \eta) &= -3\Phi_{\eta\eta\eta}(\tau, \eta) - \Phi_N(\tau, \eta) - \frac{1}{2}(\Phi_\eta(\tau, \eta))^2, \quad \tau \geq 0, \quad |\eta| \leq \frac{\ell_0}{2}, \\
D_k^\Phi(\tau, -\ell_0/2) &= D_k^\Phi(\tau, \ell_0/2), \quad \tau \geq 0, \quad k = 0, 1, 2, 3, \\
\Phi(0, \eta) &= \Phi_0(\eta), \quad |\eta| \leq \frac{\ell_0}{2},
\end{align*}$$

admits a unique solution $\Phi \in C^{1,4}([0, +\infty) \times [-\ell_0/2, \ell_0/2])$. In fact, $\Phi \in \mathbb{H}_\mathcal{T}$ for any $T > 0$. \hfill (4.19)
Most of the literature is about the differentiated version of K–S. For this reason and the reader’s convenience, we provide a full proof of Theorem 4.4 in the appendix.

According to the Ansatz, we split

\[ \psi = \Phi + \epsilon \rho, \]

which defines the remainder \( \rho \). To avoid cumbersome notation, we simply write \( \rho \) for \( \rho_\epsilon \). From Theorem 4.4 we know that \( \rho \in \mathcal{Y}_T \) (see Definition 4.1) and it solves the equation

\[ \frac{\partial}{\partial \tau} \mathcal{B}_\epsilon(\rho) = \mathcal{S}_\epsilon(\rho) - \Phi \eta \rho - \epsilon \{ D \eta \mathcal{R}(0, L_\epsilon) \left( T' - U \right) + \epsilon \mathcal{B}(0, L_\epsilon) \left( \mathcal{V} - T - \frac{4}{3} \mathcal{U} \right) \} \]

(4.20)

where

\[ \mathcal{S}_\epsilon(\xi) = \frac{17}{6} \xi \eta \eta - 3 \left\{ D \eta \mathcal{R}(0, L_\epsilon) \left( \frac{1}{2} \xi (T' - U) + \epsilon \xi \eta \left( \mathcal{V} - T - \frac{4}{3} \mathcal{U} \right) \right) \right\} \cdot (0, \cdot); \]

\[ \mathcal{B}(\Phi) = 3 \Phi \eta \eta + 3 \left\{ D \eta \mathcal{R}(0, L_\epsilon) \left[ \Phi \eta \eta \left( T' - U \right) \right] \right\} \cdot (0, \cdot) + \frac{13}{3} \Phi \eta \eta \]

\[ - 3 \epsilon \left\{ D \eta \mathcal{R}(0, L_\epsilon) \left[ \Phi \eta \eta \left( \mathcal{V} - T - \frac{4}{3} \mathcal{U} \right) \right] \right\} \cdot (0, \cdot). \]

Equation (4.20) on \([-\ell_0/2, \ell_0/2]\) is supplemented by periodic boundary conditions and by an initial condition \( \rho_0 \) at \( \tau = 0 \). For simplicity, to avoid lengthy computations, we take hereafter \( \rho_0 = 0 \), namely, \( \psi(0, \cdot) = \Phi(0, \cdot) = \Phi_0 \). In other words, the front \( \psi \) and the solution of K–S start from the same configuration, which is physically reasonable. More general compatible initial data can be considered as in [3, 1].

5. Local in time solvability of Equation (4.20)

As it has been remarked in the introduction, except for small \( \ell_0 \), where the TW is stable, global existence of \( \rho \) is not granted.

In this section, we prove the following local in time existence and uniqueness result.

**Theorem 5.1.** For any \( \epsilon \in (0, 1/2] \), there exist \( T_\epsilon > 0 \) and a unique solution \( \rho \) to Equation (4.20) which belongs to \( \mathcal{Y}_T \) (see Definition 4.1) and vanishes at \( \tau = 0 \).

The proof is rather long and needs many preliminary results. For this reason, we split it in several steps. Before entering the details, we sketch here the strategy of the proof.

As a first step, for any fixed \( \epsilon > 0 \), we transform Equation (4.20) into a semilinear equation associated with a sectorial operator. Employing classical tools from the theory of analytic semigroups we prove that such a semilinear equation admits a unique solution \( \rho = \rho_\epsilon \) defined in some time domain \([0, T_\epsilon]\), which vanishes at \( \tau = 0 \). Using some bootstrap arguments, we then regularize \( \rho \), showing that it actually belongs to \( \mathcal{Y}_T \). These regularity properties of \( \rho \) allow us to show that it is in fact a solution to Equation (4.20).

5.1. The semilinear equation. In this subsection, we show that we can transform Equation (4.20) into a semilinear equation associated with a second order elliptic
We compute the symbol of the operator $B$ extended to the whole of $C$. Formula (5.5) can be extended to any function for the reader's convenience we go into details. Even if the proof can be obtained arguing as in the proof of [4, Prop. 4.2], we know that the operator $B$ is well-defined in $C^{2+\theta}_\varepsilon$ for any $\theta \in (0,1)$. We will show that $B$ can be extended to the whole of $C^{2}_\varepsilon$ with an operator which is invertible. For this purpose, we compute the symbol of the operator $B$.

Throughout the section, given a function $f: J \times [-\ell_0/2, \ell_0/2] \to \mathbb{R}$, where $J \subset \mathbb{R}$ is an interval, we denote by $f(x,k)$ the $k$-th Fourier coefficient of the function $f(x,)$. Moreover, we set $\psi := \psi_R(\varepsilon \cdot, k)$. For any $\varepsilon > 0$, we claim that $\psi = \psi_R(\varepsilon \cdot, k)$.

We limit ourselves to dealing with the function $u$, since the same arguments apply to the function $v$. Let us first assume that $\varphi$ is smooth enough. Since the function $V - T - \frac{4}{3} U$ belongs to $(I - \mathcal{P})(\mathcal{X})$, from Proposition A.2 it follows that $u \in D(L + \varepsilon A)$, so that $Lu + \varepsilon Au = -(V - T - \frac{4}{3} U)\varphi$. Moreover, the function $\hat{u}(\cdot, k)$ belongs to $(I - \mathcal{P})(D(L))$ and solves the equation $(\varepsilon \lambda_k - L)\hat{u}(\cdot, k) = (V - T - \frac{4}{3} U)\hat{\varphi}(k)$ for any $k = 0, 1, \ldots$. Since $\lambda_k$ is in the resolvent set of the operator $L$ for any $k = 0, 1, \ldots$, by Theorem A.3 it follows that $\hat{u}(\cdot, k) = R(\varepsilon \lambda_k, L) (V - T - \frac{4}{3} U)\hat{\varphi}(k)$, $k = 0, 1, \ldots$ (5.5)

Formula (5.3) can be extended to any function $\varphi \in C^1_\varepsilon$ by a straightforward approximation argument.

From formula (A.2) it is immediate to check that

$$(R(\varepsilon \lambda_k, L)f)(1, \cdot) = \frac{2\varepsilon \lambda_k}{1 + (2\varepsilon \lambda_k - 1)X_k} \times \left[ \int_{-\infty}^{0} e^{-\nu_1 \lambda_k t} f_1(t, \cdot) dt + \int_{0}^{+\infty} e^{-\nu_2 \lambda_k t} f_2(t, \cdot) dt \right].$$
for any \( f = (f_1, f_2) \in \mathcal{R} \), where
\[
\nu_{1,k} = \frac{1}{2} - \frac{1}{2} x_k, \quad \nu_{2,k} = \frac{1}{2} + \frac{1}{2} x_k, \quad k = 0, 1, \ldots
\]
Hence, from the very definition of the functions \( V, T \) and \( U \) (see (2.1) and (2.2)), we get
\[
\left\{ (\varepsilon \lambda_k + D_x - D_x^2)^{-1} \left( V - T - \frac{4}{3} U \right) \right\}_1(0) = -\frac{8\nu_{2,k} - 5\nu_{2,k} - 3}{9\nu_{2,k}^2 x_k} = -\frac{4}{9} \frac{(X_k + 7)(X_k - 1)}{X_k(X_k + 1)^3}.
\]
Since 0 is in the resolvent set of the restriction of \( L \) to \( (I - \mathcal{P})(\mathcal{R}) \), we can extend the previous formula, by continuity, to \( \lambda = 0 \). Thus,
\[
\tilde{u}_1(0, k) = -\frac{4}{9} \frac{2\varepsilon \lambda_k}{1 + (2\varepsilon \lambda_k - 1)X_k} \left( X_k + 7 \right) \left( X_k - 1 \right) \tilde{\varphi}(k)
\]
for any \( k = 0, 1, \ldots \), and the assertion follows.

Now, using Formulae (5.3) and (5.4), it is immediate to complete the proof. \( \square \)

**Proposition 5.3.** For any \( \varepsilon \in (0, 1/2) \), the operator \( \mathcal{B}_\varepsilon \) is invertible from \( C^{2+\theta}_0 \) into \( C^0 \) for any \( \theta \in (0, 1) \).

**Proof.** From Lemma 5.2, we know that \( b_{\varepsilon,k} \neq 0 \), for any \( k \in \mathbb{N} \setminus \{0\} \). Hence, operator \( \mathcal{B}_\varepsilon \) admits a realization in \( L^2 \) which is invertible from \( H^2 \) into \( L^2 \). We still denote by \( \mathcal{B}_\varepsilon \) such a realization. To prove that \( \mathcal{B}_\varepsilon \) is invertible from \( C^2_0 \) into \( C^2_0 \), let us fix \( f \in C^2_0 \) and let \( u \in H^2 \) be the unique solution to the equation \( \mathcal{B}_\varepsilon u = f \). Taking (5.2) into account, it is immediate to check that, we can split \( \mathcal{B}_\varepsilon = -3\varepsilon D_{\eta\eta} + \mathcal{B}_\varepsilon \), where \( \mathcal{B}_\varepsilon \) is a bounded operator, whose symbol \( (\mathcal{B}_\varepsilon) \) satisfies
\[
\mathcal{B}_\varepsilon \sim \frac{3}{2} \frac{\varepsilon \lambda_k}{\lambda_k}, \quad (k \to +\infty).
\]
It follows that the function \( \mathcal{B}_\varepsilon(u) \) is in \( C^2_0 \). By difference \( u_{\eta\eta} \) is in \( C^2_0 \) as well. A bootstrap argument can now be used to prove that, if \( f \in C^2_0 \), then \( u \in C^{2+\theta}_0 \). \( \square \)

In view of Proposition 5.3, we can invert the operator \( \mathcal{B}_\varepsilon \) from \( C^{2+\theta}_0 \) into \( C^0 \) for any \( \theta \in (0, 1) \), getting the following equation for \( \rho \):
\[
\rho \tau(\tau, \cdot) = \mathcal{B}_\varepsilon(\rho(\tau, \cdot) + \mathcal{H}_\varepsilon(\tau, \rho_\eta(\tau, \cdot))), \quad \tau \in [0, T], \quad \theta \in (0, 1), \quad \theta \in (0, 1), \quad (5.6)
\]
where
\[
\mathcal{B}_\varepsilon(\rho) = \mathcal{B}_\varepsilon^{-1}(\mathcal{B}_\varepsilon(\rho)), \quad \mathcal{B}_\varepsilon^{-1}(\mathcal{B}_\varepsilon(\rho)) = \mathcal{B}_\varepsilon^{-1}(\mathcal{B}_\varepsilon((\Phi_\eta(\tau, \cdot))^2)) = \mathcal{B}_\varepsilon^{-1}(\Phi_\eta(\tau, \cdot)\rho) + \mathcal{B}_\varepsilon(\Phi_\eta(\tau, \cdot)\rho)
\]
\[
- \varepsilon \mathcal{B}_\varepsilon^{-1}(\rho^2) + \varepsilon^2 \mathcal{B}_\varepsilon^{-1}(\mathcal{B}_\varepsilon(\rho^2)) + 3 \mathcal{B}_\varepsilon^{-1}(\Phi_{\eta\eta\rho}) + 3 \mathcal{B}_\varepsilon^{-1}(D_{\eta\eta} R(0, L_\varepsilon)(\Phi_{\eta\eta}(\mathbf{T} - \mathbf{U}))(\cdot, 0, \cdot)) + \frac{13}{3} \mathcal{B}_\varepsilon^{-1}(\Phi_{\tau\eta})
\]
exists a positive constant $C$ for any bounded from $\mathbb{R}$ into account, it is immediate to check that the operator $\mathcal{A}$ is well-defined in $C^4$.

Actually, we show that it can be extended to $C^1 \cap C^2$ with a bounded operator which is sectorial.

**Proposition 5.4.** For any $\varepsilon \in (0,1/2]$, the operator $\mathcal{A}_\varepsilon$ can be extended with a sectorial operator $R_\varepsilon$ having $C^1 \cap C^2$ as domain. Moreover, $D_{R_\varepsilon}(\theta,\infty) = C^2$ for any $\theta \in (0,1) \setminus \{1/2\}$, with equivalence of the corresponding norms.

**Proof.** To begin with, we compute the symbol of the operator $\mathcal{A}_\varepsilon$. We have:

$$s_k = \frac{3(X_k - 1)(X_k + 1)^2((\varepsilon - 1)X_k^2 + (\varepsilon - 1)X_k + 2)}{16\varepsilon^2(X_k + 2)} \sim 48(\varepsilon - 1)\varepsilon^3 \lambda_k^2,$$

as $k \rightarrow +\infty$. Hence, from (5.2) and (5.8) it follows that the $k$-th symbol of the operator $\mathcal{A}_\varepsilon$ is

$$r_k = \frac{(X_k^2 - 1)((\varepsilon - 1)X_k^2 + (\varepsilon - 1)X_k + 2)}{4\varepsilon^2(X_k^2 + 2X_k - 1)}, \quad k = 0, 1, \ldots$$

At any fixed $\varepsilon \in (0,1/2]$ $r_k \sim (1 - \varepsilon^{-1})\lambda_k$ as $k \rightarrow +\infty$. Hence, we can split

$$\mathcal{A}_\varepsilon \varphi = \frac{1 - \varepsilon}{\varepsilon} \varphi_{yy} + \mathcal{A}_\varepsilon^{(1)} \varphi,$$

where the symbol of $\mathcal{A}_\varepsilon^{(1)}$ is

$$r_k^{(1)} = \frac{(X_k^2 - 1)((1 - \varepsilon)X_k + \varepsilon + 1)}{4\varepsilon^2(X_k^2 + 2X_k - 1)} \sim \frac{(1 - \varepsilon)\sqrt{\varepsilon}}{2\varepsilon^2} \sqrt{\lambda_k}, \quad (k \rightarrow +\infty).$$

We claim that the operator $\mathcal{A}_\varepsilon^{(1)}$ admits a realization in $C([-\ell_0/2, \ell_0/2])$ which is a bounded operator mapping $C^{1+\alpha}_s$ (for any $\alpha \in (0,1)$) into $C^1_s$.

As a first step, we observe that, due to the characterization of the spaces $H^s$ given in (2.3), the operator $\mathcal{A}_\varepsilon^{(1)}$ admits a realization $R_\varepsilon^{(1)}$ which is bounded from $H^s$ into $H^{s-1}$ for any $s \geq 1$. It is well-known that $C^m_0 \subset H^m \subset C^{m-1/2}_s$ with continuous embeddings, for any $m > 1/2$ such that $m - 1/2 \notin \mathbb{N}$. As a consequence, the operator $R_\varepsilon^{(1)}$ is bounded from $C^m_s$ into $C^{s-3/2}_s$ for any $s > 3/2$ such that $s - 3/2 \notin \mathbb{N}$. Therefore, the operator $\mathcal{A}_\varepsilon$ can be extended with a bounded operator $R_\varepsilon$ from $D(R_\varepsilon) = C^1_s \cap C^2_s$ into $C([-\ell_0/2, \ell_0/2])$.

Let us now prove that $R_\varepsilon$ is sectorial. For this purpose, we note that $C^1_s$ belongs to the class $J_{\theta/2}$ between $C([-\ell_0/2, \ell_0/2])$ and $C^1_s \cap C^2_s$, for any $\theta \in (0,2)$, i.e., there exists a positive constant $K$ such that

$$\|f\|_{C^m([-\ell_0/2, \ell_0/2])} \leq K \|f\|_{C([-\ell_0/2, \ell_0/2])} \|f\|_{C^2_s}, \quad (5.9)$$

for any $f \in C^1_s \cap C^2_s$, and the realization of the second order derivative in $C([-\ell_0/2, \ell_0/2])$ with domain $C^1_s \cap C^2_s$ is sectorial. Hence, we can apply [3] Prop.
2.4.1(i)] and conclude that the operator \( R_\varepsilon \) is sectorial in \( C([-\ell_0/2, \ell_0/2]) \). From the above arguments, it is now clear that the graph norm of \( R_\varepsilon \) is equivalent to the Euclidean norm of \( C^1_\alpha \cap C^2 \). Hence, \([8, \text{Prop. 2.2.2}]\) implies that \( D_{R_\varepsilon}(\theta, \infty) = C^2_{2\alpha} \) for any \( \theta \in (0, 1) \setminus \{1/2\} \). \( \square \)

We now consider the operator \( \mathcal{K}_\varepsilon \). From Proposition \( \mathcal{K}_\varepsilon \) and Theorems \( \mathcal{K}_\varepsilon \), \( A.2(iii) \), we know that the operator \( \mathcal{K}_\varepsilon \) is continuous from \( C^s_\alpha \) into \([0, +\infty) \times C^s_\alpha \) for any \( \alpha > 0 \).

Proposition 5.5. For any \( \varepsilon \in (0, 1/2] \), the operator \( \mathcal{K}_\varepsilon \) can be extended with a continuous operator mapping \( C^s_\alpha \) into \([0, +\infty) \times C^s_\alpha \) for any \( s \in [0, 2] \). Moreover, for any \( T > 0 \) and any \( r > 0 \), there exists a positive constant \( K = K(T, r) \) such that
\[
\| \mathcal{K}_\varepsilon(\tau_2, \psi) - \mathcal{K}_\varepsilon(\tau_1, \psi) \|_\infty + \| \mathcal{K}_\varepsilon(\tau, \psi) - \mathcal{K}_\varepsilon(\tau, \xi) \|_\infty \leq K (|\tau_2 - \tau_1| + \|\psi - \xi\|_\infty)
\]
for any \( \tau, \tau_1, \tau_2 \in [0, T] \) and any \( \psi, \xi \in B(0, r) \subset C^s_\alpha \).

Proof. As a first step, we observe that, using Formulae \( (5.3) \) and \( (5.4) \), one can easily show that the \( k \)-th symbol \( g_k \) of the operator \( \mathcal{G}_\varepsilon \) is
\[
g_k = -\lambda_k \frac{3X_k^2 + 15X_k + 4}{2(X_k + 1)(X_k + 2)}.
\]
(5.10)

From \( (5.2) \) and \( (5.10) \), it follows that the symbol of the operator \( \mathcal{Z}_\varepsilon := \mathcal{B}_\varepsilon^{-1} \mathcal{G}_\varepsilon \) is
\[
z_k = -\frac{2}{3} \left( \frac{3X_k^2 + 15X_k + 4}{(X_k + 1)^2(X_k + 2) - 1} \right) = -\frac{1}{2\varepsilon} + z_k^{(1)},
\]
where
\[
z_k^{(1)} \sim -\frac{1}{4\sqrt{\varepsilon}^{3}\lambda_k}, \quad k \to +\infty.
\]
(5.11)

Hence, we can write
\[
\mathcal{Z}_\varepsilon = -\frac{1}{2\varepsilon} Id + \mathcal{Z}_\varepsilon^{(1)}.
\]

Formula \( (5.11) \) shows that the operator \( \mathcal{Z}_\varepsilon^{(1)} \) is bounded from \( H^s \) into \( H^{s+1} \) for any \( s \geq 0 \). Hence, it is bounded from \( C^1_\alpha \) into \( C^{1+\theta}_\alpha \) for any \( s \in \mathbb{N} \cup \{0\} \) and any \( \theta \in (0, 1/2) \). As a byproduct, the operator \( \mathcal{Z}_\varepsilon \) is bounded from \( C^s_\alpha \) into itself for any \( s \geq 0 \). Since,
\[
\mathcal{K}_\varepsilon(\tau, \psi) = \mathcal{Z}_\varepsilon((\Phi_\eta(\tau, \cdot))^2) - \mathcal{B}_\varepsilon^{-1}(\Phi_\eta(\tau, \cdot)\psi) + 2\varepsilon \mathcal{Z}_\varepsilon(\Phi_\eta(\tau, \cdot)\psi) - \frac{\varepsilon^2}{2} \mathcal{B}_\varepsilon^{-1}(\psi^2)
\]
\[
+ \varepsilon^2 \mathcal{Z}_\varepsilon(\psi^2) + 3 \mathcal{B}_\varepsilon^{-1}(\Phi_{\eta\eta\eta\eta}) + \frac{13}{3} \mathcal{B}_\varepsilon^{-1}(\Phi_{\eta\eta})
\]
\[
+ 3 \mathcal{B}_\varepsilon^{-1} \left\{ (D_{\eta\eta}R(0, L_\varepsilon)[\Phi_{\eta\eta}(\mathbf{T} - U)]) (\cdot, 0, \cdot) \right\}
\]
\[
- 3\varepsilon \mathcal{B}_\varepsilon^{-1} \left\{ (D_{\eta\eta}R(0, L_\varepsilon)[\Phi_{\eta\eta}(\mathbf{V} - \mathbf{T} - \frac{4}{3} U)]) (\cdot, 0, \cdot) \right\},
\]
for any \( \psi \in C^s_\alpha \), taking Proposition \( 5.3 \) and Theorem \( 4.4 \) into account, the assertion follows at once. \( \square \)

From all the previous results, we get the following:
Theorem 5.6. For any $\varepsilon \in (0, 1/2]$, Equation (5.6) admits a unique solution $\rho$ defined in a maximal time domain $[0, T_\varepsilon)$ which vanishes at $\tau = 0$, belongs to $C^{1,2}([0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2])$ and satisfies $D_\eta^{(j)}\rho(\cdot, \ell_0/2) \equiv D_\eta^{(j)}\rho(\cdot, 0)$ for $j = 0, 1$.

Proof. Combining Thms 7.1.2 and 4.3.8, we can easily show that Equation (5.4) admits a unique solution $\rho$, defined in a maximal time domain $[0, T_\varepsilon)$, which belongs to $C^{1,2}([0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2])$ for any $\beta < 2$, vanishes at $\tau = 0$, and satisfies $D_\eta^{(j)}\rho(\cdot, \ell_0/2) \equiv D_\eta^{(j)}\rho(\cdot, 0)$ for $j = 0, 1$. Moreover, $R_\varepsilon(\rho)$ is continuous in $[0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2]$. Since $R_\varepsilon(\rho)$ and $\frac{1}{\varepsilon^2}D_\eta\rho$ differ in the lower order operator $R_\varepsilon^{(1)}$ (see the proof of Proposition 5.4), $\rho_{\eta\eta} \in C([0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2])$, as well, and this completes the proof. \[ \square \]

5.3. Proof of Theorem 5.3. In this subsection, using some bootstrap arguments, we show that the solution $\rho$ to the Equation (5.6), whose existence has been guaranteed in Theorem 5.6 is actually a solution to Equation (4.20). Of course, we just need to show that both the functions $\rho_{\eta\eta}$ and $\rho_\tau$ belong to $C^{0,2}(0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2)$. Throughout the proof, we assume that $T'$ is any arbitrarily fixed real number in the interval $(0, T_\varepsilon)$.

To begin with, we observe that, from Thms 4.3 and Proposition 5.3, it follows immediately that the function $\mathcal{X}_\varepsilon$ is continuous in $[0, T')]$ with values in $D_{R_\varepsilon}(\theta, \infty)$ for any $\theta \in (0, 1)$ (see Proposition 5.4), since the operator $\mathcal{Z}_\varepsilon$ is bounded from $C^2_\varepsilon$ into itself for any $s \geq 0$, by the proof of Proposition 5.3, and an interpolation argument. Therefore, we can apply Thm. 4.3.8 and conclude that $\rho_{\tau}, R_\varepsilon(\rho)$ are bounded in $[0, T']$ with values in $C^{2\theta}_{\varepsilon}$ for any $\theta \in (0, 1)$. As it has been already remarked, $R_\varepsilon(\rho)$ and $\frac{1}{\varepsilon^2}D_\eta\rho$ differ in the lower order operator $R_\varepsilon^{(1)}$. Hence, $\rho_{\eta\eta} \in C^{0,2\theta}(0, T'] \times [-\ell_0/2, \ell_0/2])$ for any $\theta$ as above. In particular, $\rho_{\tau}$ and $\rho_{\eta\eta}$ are continuously differentiable with respect to $\eta$ in $[0, T'] \times [-\ell_0/2, \ell_0/2]$.

Let us now set $\zeta = \rho_\eta$. The previous results show that $\zeta \in C([0, T_\varepsilon); C^2_\varepsilon)$ and $C^1([0, T_\varepsilon); C^2_\varepsilon)$ and $\zeta_\tau = \rho_{\eta\eta}$. Clearly, $\zeta_\tau = (1 - \varepsilon^{-1})\zeta_{\eta\eta} + D_\eta R_\varepsilon^{(1)}(\rho) + D_\eta \mathcal{X}_\varepsilon(\cdot, \rho_\eta)$ in $[0, T_\varepsilon) \times [-\ell_0/2, \ell_0/2]$, and $\zeta_{(0, \cdot)} \equiv 0$. Since the operator $R_\varepsilon^{(1)}$ is bounded from $C^{3+\theta}_{\varepsilon}$ into $C^{2+\theta}_{\varepsilon}$ for any $\theta \in (0, 1) \setminus \{1/2\}$, the function $D_\eta R_\varepsilon^{(1)}(\rho)$ is bounded in $[0, T']$ with values in $C^2_{\varepsilon}$ for any $\alpha < 3/2$. Since the function $D_\eta \mathcal{X}_\varepsilon(\cdot, \rho_\eta)$ is bounded in $[0, T']$ with values in $C^2_{\varepsilon}$, as well, it follows that $D_\eta R_\varepsilon^{(1)}(\rho) + D_\eta \mathcal{X}_\varepsilon(\cdot, \rho_\eta(\cdot, \cdot))$ is bounded in $[0, T']$ with values in $C^2_{\varepsilon}$ for any $\alpha$ as above. Hence, Thorem 4.3.9(iii) of Thm 3 implies that the functions $\zeta_\tau$ and $\zeta_{\eta\eta}$ are bounded (in fact, continuous) in $[0, T']$ with values in $C^2_{\varepsilon}$. This completes the proof.

6. Uniform existence of $\rho$ and proof of the main result

So far we have only proved a local existence-uniqueness result for Equation (4.20). In this section, we want to prove that, for any fixed $T > 0$, the local solution $\rho$ exists in the whole of $[0, T]$, at least for sufficiently small value of $\varepsilon$. The main tool in this direction is represented by the $a$ priori estimates in the next subsection.

6.1. A priori estimates. The main result of this subsection is contained in the following theorem.
Theorem 6.1. For any $T > 0$, there exist $\varepsilon_0 = \varepsilon_0(T) \in (0, 1/2)$ and $K = K(T) > 0$ such that, if $\rho \in \mathcal{F}_T$ (see Definition 4.1), is a solution to Equation (4.20), then

$$
\sup_{\tau \in (-\ell/2, \ell/2)} |\rho_\eta(\tau, \eta)| + \sup_{\tau \in (0, T]} \int_{-\ell/2}^{\ell/2} (\rho_{\eta\eta}(\tau, \eta))^2 d\eta
$$

$$
+ \int_0^T \int_{-\ell/2}^{\ell/2} (\rho_\tau(\tau, \eta))^2 d\eta d\tau + \int_0^T \int_{-\ell/2}^{\ell/2} (\rho_\tau^2(\tau, \eta))^2 d\eta d\tau \leq K,
$$

for all $\tau \in (0, T]$, whenever $\varepsilon \leq \varepsilon_0$.

The proof of Theorem 6.1 is obtained employing an energy method. Let $\rho \in \mathcal{F}_T$ solve (4.20), i.e., the equation

$$
\frac{\partial}{\partial \tau} \mathcal{E}(\rho) = \mathcal{F}(\rho) - \Phi_\eta \rho_\eta - \frac{\varepsilon}{2}(\rho_\eta)^2 + \mathcal{E}_\varepsilon((\Phi_\eta + \varepsilon \rho_\eta)^2) + \mathcal{K}(\Phi),
$$

(6.1)

for some $T > 0$. Multiplying both the sides of (6.1) by $\rho_\tau$ and integrating over $[-\ell/2, \ell/2]$, we get

$$
\int_{-\ell/2}^{\ell/2} \mathcal{E}(\rho_\tau) \rho_\tau d\eta = \int_{-\ell/2}^{\ell/2} \mathcal{E}(\rho) \rho_\tau d\eta - \int_{-\ell/2}^{\ell/2} \Phi_\eta \rho_\eta \rho_\tau d\eta - \frac{\varepsilon}{2} \int_{-\ell/2}^{\ell/2} (\rho_\eta)^2 \rho_\tau d\eta
$$

$$
+ \int_{-\ell/2}^{\ell/2} \mathcal{E}_\varepsilon((\Phi_\eta + \varepsilon \rho_\eta)^2) \rho_\tau d\eta + \int_{-\ell/2}^{\ell/2} \mathcal{K}(\Phi) \rho_\tau d\eta.
$$

(6.2)

Using the very definition of the operator $\mathcal{E}_\varepsilon$ (see (4.17)) and then integrating by parts, yields

$$
\int_{-\ell/2}^{\ell/2} \mathcal{E}(\rho) \rho_\tau d\eta
$$

$$
= \int_{-\ell/2}^{\ell/2} \{-3(1 - \varepsilon)\rho_{\eta\eta\eta} - \rho_\eta + 3\varepsilon (D_{\eta\eta} R(0, L_\varepsilon)[\rho_{\eta\eta}(T' - U)] (\cdot, 0, \cdot)) \rho_\tau d\eta
$$

$$
= -\frac{3}{2} (1 - \varepsilon) \frac{d}{d\tau} \int_{-\ell/2}^{\ell/2} (\rho_\eta)^2 d\eta - \int_{-\ell/2}^{\ell/2} \rho_\eta \rho_\tau d\eta
$$

$$
+ 3\varepsilon \int_{-\ell/2}^{\ell/2} (D_{\eta\eta} R(0, L_\varepsilon)[\rho_{\eta\eta}(T' - U)] (\cdot, 0, \cdot)) \rho_\tau d\eta.
$$

Therefore, we can write Equation (6.2) in the following equivalent form:

$$
\frac{3}{2} (1 - \varepsilon) \frac{d}{d\tau} \int_{-\ell/2}^{\ell/2} (\rho_\eta)^2 d\eta + \int_{-\ell/2}^{\ell/2} \mathcal{E}(\rho_\tau) \rho_\tau d\eta
$$

$$
= -\frac{\varepsilon}{2} \int_{-\ell/2}^{\ell/2} (\rho_\eta)^2 \rho_\tau d\eta - \int_{-\ell/2}^{\ell/2} \rho_\eta \rho_\tau d\eta
$$

$$
+ 3\varepsilon \int_{-\ell/2}^{\ell/2} (D_{\eta\eta} R(0, L_\varepsilon)[\rho_{\eta\eta}(T' - U)] (\cdot, 0, \cdot)) \rho_\tau d\eta
$$

$$
+ \int_{-\ell/2}^{\ell/2} \mathcal{E}_\varepsilon((\Phi_\eta + \varepsilon \rho_\eta)^2) \rho_\tau d\eta - \int_{-\ell/2}^{\ell/2} \Phi_\eta \rho_\eta \rho_\tau d\eta + \int_{-\ell/2}^{\ell/2} \mathcal{K}(\Phi) \rho_\tau d\eta.
$$

(6.3)
In the following lemmata, we estimate the terms

\[ I_1 := \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} B_\varepsilon(\rho_{\tau}) \rho_{\tau} d\eta, \]

\[ I_2 := \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} (D_{\eta\eta} R(0, L_\varepsilon) [\rho_{\eta\eta}(T' - U)]) (\cdot, 0, \cdot) \rho_{\tau} d\eta, \]

\[ I_3 := \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} G_\varepsilon(\Phi_{\eta} + \varepsilon \rho_{\eta})^2 \rho_{\tau} d\eta, \]

\[ I_4 := \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} H_\varepsilon(\Phi) \rho_{\tau} d\eta. \]

The main issue is to control \( I_1 \). We have the following

**Lemma 6.2.** It holds that

\[ I_1(\tau) \geq \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} (\rho(\tau, \cdot))^2 d\eta + 3\varepsilon \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} (\rho_\eta(\tau, \cdot))^2 d\eta, \]

for any \( \tau \in [0, T] \) and any \( \varepsilon \in (0, 1/2] \).

**Proof.** Of course, we can limit ourselves to proving the estimate with \( \rho_{\tau}(\tau, \cdot) \) being replaced by \( \varphi \in H^2 \).

It is immediate to check that

\[ \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} B_\varepsilon(\varphi) \varphi d\eta = \sum_{k=0}^{+\infty} b_{\varepsilon,k} |\hat{\varphi}(k)|^2, \]

where the symbol \((b_{\varepsilon,k})\) of the operator \( B_\varepsilon \) is defined by (3.2). Note that \( b_{\varepsilon,k} = h(X_{\varepsilon,k}) \) for any \( k = 0, 1, \ldots, \), where the function \( h : [1, +\infty) \to \mathbb{R} \) is defined by

\[ h(s) = \frac{3(s + 1)(s^2 + 2s - 1)}{s + 2}, \quad s \geq 1. \]

Since \( h(s) \geq (3s + 1)/4 \) for any \( s \geq 1 \), we can estimate

\[ \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} B_\varepsilon(\varphi) \varphi d\eta \geq \sum_{k=0}^{+\infty} (1 + \varepsilon \lambda_k)|\hat{\varphi}(k)|^2 = \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} |\varphi|^2 d\eta - 3\varepsilon \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} \varphi_{\eta\eta} d\eta \]

\[ = \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} |\varphi|^2 d\eta + 3\varepsilon \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} |\varphi|^2 d\eta, \]

and we are done. \( \square \)

We now consider the terms \( I_2, I_3 \) and \( I_4 \).

**Lemma 6.3.** For any \( \tau \in [0, T] \) and any \( \varepsilon \in (0, 1/2] \), it holds that

\[ |I_2(\tau)| \leq \frac{1}{12\varepsilon} \|\rho_{\tau}(\tau, \cdot)\|_2 \|\rho_{\eta\eta}(\tau, \cdot)\|_2. \]

**Proof.** As it is immediately seen, for any \( \tau \in [0, T] \) we can estimate

\[ \left| \int_{t_0}^{t_0 + \ell_0^2 - \ell_0^2} (D_{\eta\eta} R(0, L_\varepsilon) [\rho_{\eta\eta}(T' - U)]) (\tau, 0, \cdot) \rho_{\tau}(\tau, \cdot) d\eta \right| \]
\[
\leq \frac{1}{3\epsilon} \|\varphi(\tau, \cdot)\|_2 \| (D_{\eta\eta} R(0, L_\epsilon)[\rho_{\eta\eta}(\mathbf{T}' - \mathbf{U})]) (\tau, 0, \cdot)\|_2.
\]

To compute the \(L^2\)-norm of the function \((D_{\eta\eta} R(0, L_\epsilon)[\rho_{\eta\eta}(\mathbf{T}' - \mathbf{U})]) (\tau, 0, \cdot)\), we take advantage of Formula (5.4), which allows us to estimate
\[
\| (D_{\eta\eta} R(0, L_\epsilon)[\rho_{\eta\eta}(\mathbf{T}' - \mathbf{U})]) (\tau, 0, \cdot)\|_2^2 = \frac{1}{4} \sum_{k=0}^{+\infty} \left[ \frac{X_k + 1}{X_k + 2} \lambda_k^2 \hat{\varphi}(\tau, k) \right]^2
\]
where, as usual, \(X_k = \sqrt{1 + 4\epsilon\lambda_k}\) and \(\hat{\varphi}(\tau, k)\) is the \(k\)-th Fourier coefficient of the function \(\varphi(\tau, \cdot)\). This accomplishes the proof. \(\square\)

**Lemma 6.4.** There exists a positive constant \(C\), independent of \(\epsilon \in (0, 1/2]\) and \(\tau \in [0, T]\), such that
\[
|\mathcal{R}_3(\tau)| \leq C \left( \|\varphi(\tau, \cdot)\|_2 + \|\varphi(\tau, \cdot)\|_2 \|\rho_{\eta\eta}(\tau, \cdot)\|_2 + \epsilon \|\varphi(\tau, \cdot)\|_2 \|\rho_{\eta\eta}(\tau, \cdot)\|_2^2 + \epsilon^2 \|\varphi(\tau, \cdot)\|_2 \|\rho_{\eta\eta}(\tau, \cdot)\|_2 \right),
\]
for any \(\tau \in [0, T]\).

**Proof.** As in the proof of the previous lemma, it is enough to estimate the \(L^2\)-norm of the function \(\mathcal{Y}_\epsilon(\Phi_{\eta}(\tau, \cdot) + \epsilon \rho_{\eta}(\tau, \cdot))^2\). For this purpose, we observe that we can estimate the \(L^2\)-norm of the function \(\mathcal{Y}_\epsilon(\psi)\), for any \(\psi \in H^2\), by
\[
\|\mathcal{Y}_\epsilon(\psi)\|_2^2 = \sum_{k=0}^{+\infty} \lambda_k^2 \left( \frac{3X_k^2 + 15X_k + 4}{2(X_k + 1)(X_k + 2)} \right)^2 |\hat{\psi}(k)|^2
\]
where \(X_k = \sqrt{1 + 4\epsilon\lambda_k}\) for any \(k = 0, 1, \ldots\) It follows that
\[
\|\mathcal{Y}_\epsilon(\psi)\|_2 \leq 2\|\psi_{\eta\eta}\|_2.
\] (6.4)
Moreover, the symbol \(g_k\) can be split as follows:
\[
g_k = -\frac{3}{2} \lambda_k + \frac{1}{4\epsilon} h(X_k), \quad k = 0, 1, \ldots,
\]
where the function \(h : [1, +\infty) \to \mathbb{R}\) is defined by
\[
h(s) = \frac{3s - 1}{s^2 + 2}, \quad s \geq 1.
\]
Clearly, \(0 \leq h(s) \leq 1\) for any \(s \geq 1\). Hence, we can split
\[
\mathcal{Y}_\epsilon(\psi) = \frac{3}{2} \psi_{\eta\eta} + \frac{1}{4\epsilon} \mathcal{Y}_\epsilon^{(1)}(\psi),
\] (6.5)
where the operator \(\mathcal{Y}_\epsilon^{(1)}\) is well-defined in \(L^2\) and
\[
\|\mathcal{Y}_\epsilon^{(1)}(\psi)\|_2 \leq 3\|\psi\|_2.
\] (6.6)
To estimate the terms $I$, we can continue Estimate (6.9) and obtain

\[ \int_{0}^{T} \mathcal{F}_\varepsilon((\Phi_\eta(\tau, \cdot) + \varepsilon \rho_\eta(\tau, \cdot))^2) \rho_\tau(\tau, \cdot) \, d\eta \]

\[ \begin{aligned} & = \int_{0}^{T} \mathcal{F}_\varepsilon((\Phi_\eta(\tau, \cdot))^2) \rho_\tau(\tau, \cdot) \, d\eta + 2\varepsilon \int_{0}^{T} \mathcal{F}_\varepsilon(\Phi_\eta(\tau, \cdot) \rho_\eta(\tau, \cdot)) \rho_\tau(\tau, \cdot) \, d\eta \\
 & \quad + \varepsilon^2 \int_{0}^{T} \mathcal{F}_\varepsilon((\rho_\eta(\tau, \cdot))^2) \rho_\tau(\tau, \cdot) \, d\eta := J_1(\tau) + J_2(\tau) + J_3(\tau). \end{aligned} \]

To estimate $J_1$, we use Formula (6.4) and Hölder inequality to get

\[ |J_2(\tau)| \leq 2\|\rho_\tau(\tau, \cdot)\|_2 \|(\Phi_\eta(\tau, \cdot))^2\|_2. \quad (6.7) \]

Estimating the terms $J_2$ and $J_3$ is a bit more tricky. Using Formulae (6.3) and (6.4), we get

\[ |J_2(\tau)| \leq 3\varepsilon \int_{0}^{T} \rho_\tau(\tau, \cdot)(\Phi_\eta(\tau, \cdot) \rho_\eta(\tau, \cdot)) \, d\eta \]

\[ \begin{aligned} & + \frac{3}{2}\|\Phi_\eta(\tau, \cdot) \rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2 \\
 & + \frac{3}{2}\|\Phi_\eta(\tau, \cdot) \rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2 \\
 & \leq 3\varepsilon\|\Phi_\eta\|_\infty \|\rho_\tau(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2 \\
 & + \frac{3}{2}\|\Phi_\eta\|_\infty \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2. \quad (6.8) \end{aligned} \]

Using a Poincaré-Wirtinger inequality, we can continue Estimate (6.9) and obtain

\[ |J_2(\tau)| \leq C_1 \varepsilon \|\rho_\tau(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_2 + \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2. \quad (6.9) \]

To estimate the term $J_3(\tau)$, we can argue similarly. Therefore,

\[ |J_3(\tau)| \leq \frac{3}{2}\varepsilon^2 \int_{0}^{T} \rho_\tau(\tau, \cdot)((\rho_\eta(\tau, \cdot))^2) \, d\eta \]

\[ \begin{aligned} & + \frac{3}{4}\varepsilon \int_{0}^{T} |(\rho_\eta(\tau, \cdot))^2| \rho_\tau(\tau, \cdot) \, d\eta \\
 & \leq 3\varepsilon^2 \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_\infty \|\rho_\eta(\tau, \cdot)\|_2 + \frac{3}{4}\varepsilon \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\tau(\tau, \cdot)\|_2 \\
 & \leq 3\varepsilon^2 \sqrt{6}\|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_2 ^2 + \frac{3}{4}\varepsilon \|\rho_\eta(\tau, \cdot)\|_2 ^2 \|\rho_\tau(\tau, \cdot)\|_2. \quad (6.10) \end{aligned} \]

Combining Estimates (6.7), (6.8) and (6.10) together, the assertion follows at once. □

**Lemma 6.5.** There exists a positive constant $C$, independent of $\varepsilon \in (0, 1/2]$ and $\tau \in [0, T]$, such that

\[ |J_4(\tau)| \leq C \left( \|\Phi(\tau, \cdot)\|_2 + \|\Phi(\tau, \cdot)\|_2 \right) \|\rho_\tau(\tau, \cdot)\|_2, \quad \tau \in [0, T]. \quad (6.11) \]
Proof. Of course, we just need to estimate the terms

\[
J_4^{(1)}(\tau) = \varepsilon \int_{-\infty}^{\infty} \rho_x \left( D_{\eta^{(2)}} R(0, L_\varepsilon \left( \Phi_{\tau \eta^{(2)}} \left( V - T - \frac{4}{3} U \right) \right) \right) (\cdot, 0, \cdot) d\eta,
\]

\[
J_4^{(2)}(\tau) = \int_{-\infty}^{\infty} \rho_x \left( D_{\eta^{(2)}} R(0, L_\varepsilon \left( \Phi_{\eta^{(2)}} (T' - U) \right) \right) (\cdot, 0, \cdot),
\]

the other remaining terms are easily to be handled with.

Concerning \( J_4^{(1)} \), taking (5.3) into account we can estimate

\[
|J_4^{(1)}(\tau)| \leq \frac{4}{9} \varepsilon \sum_{k=0}^{+\infty} \lambda^2_k \frac{4X_k + 7}{(X_k + 1)^2(X_k + 2)} |\hat{\rho}_x(\tau, k)||\hat{\Phi}_x(\tau, k)|
\]

\[
\leq \frac{1}{9} \varepsilon \sum_{k=0}^{+\infty} \lambda_k \frac{X_k^2(4X_k + 7)}{(X_k + 1)^2(X_k + 2)} |\hat{\rho}_x(\tau, k)||\hat{\Phi}_x(\tau, k)|
\]

\[
\leq \frac{4}{9} \varepsilon \sum_{k=0}^{+\infty} \lambda_k |\hat{\rho}_x(\tau, k)||\hat{\Phi}_x(\tau, k)|
\]

\[
= \frac{4}{9} \varepsilon |\rho_x(\tau, \cdot)|_2 |\Phi_{\tau \eta^{(2)}}(\tau, \cdot)|_2.
\]

for any \( \tau \in [0, T] \). Similarly, using (7.4) we can estimate

\[
|J_4^{(2)}(\tau)| \leq \frac{2}{3} \varepsilon \sum_{k=0}^{+\infty} \lambda^2_k \frac{1}{(X_k + 1)(X_k + 2)} |\hat{\rho}_x(\tau, k)||\hat{\Phi}_x(\tau, k)|
\]

\[
\leq \frac{1}{3} \varepsilon \sum_{k=0}^{+\infty} \lambda_k |\hat{\rho}_x(\tau, k)||\hat{\Phi}(\tau, k)|
\]

\[
= \frac{1}{3} \varepsilon |\rho_x(\tau, \cdot)|_2 |\Phi_{\eta^{(2)}}(\tau, \cdot)|_2.
\]

for any \( \tau \in [0, T] \). Now estimate (6.11) follows immediately. \( \square \)

Finally, we recall the following result proved in [1] which plays a crucial role in the proof of Theorem 1.1.

Lemma 6.6 (slight extension of Lemma 3.1 of [1]). Let \( A_0, C_0, C_1, C_2 \) be positive constants. For any \( T > 0 \), there exist \( \varepsilon_0 \in (0, 1/2) \) and a constant \( K_0 \) such that, if \( A_\varepsilon \in C^1([0, T']) \) (\( T' \in (0, T) \)) satisfies

\[
\begin{aligned}
A'_\varepsilon(\tau) &\leq C_0 + C_1 A_\varepsilon(\tau) + C_2 \varepsilon (A_\varepsilon(\tau))^2, & \tau \in [0, T'],
\quad A_\varepsilon(0) \leq A_0,

A_\varepsilon(\tau) &\leq K_0, & \tau \in [0, T_0],
\end{aligned}
\]

for some \( \varepsilon \in (0, \varepsilon_0] \), then \( A_\varepsilon(\tau) \leq K_0 \) for any \( \tau \in [0, T_0] \).

Proof of Theorem 1.1. To begin with, we observe that, taking Poincaré-Wirtinger inequality into account, we can estimate

\[
\left| \int_{-\infty}^{\infty} (\rho_\eta(\tau, \cdot) \rho_\tau(\tau, \cdot) dp_\eta(\cdot)) \right| \leq \|\rho_\tau(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_\infty \leq \sqrt{\varepsilon_0} \|\rho_\tau(\tau, \cdot)\|_2 \|\rho_\eta(\tau, \cdot)\|_2^2.
\]
for any $\tau \in [0, T]$. Hence, from Lemmata 6.2, 6.3 and estimate (6.3), and using Hölder inequality, we get

$$
\frac{3}{2}(1 - \varepsilon) \frac{d}{d\tau} \| \rho_{qy}(\tau, \cdot) \|_2^2 + \| \rho_\tau(\tau, \cdot) \|_2^2 + 3\varepsilon \| \rho_{qy}(\tau, \cdot) \|_2^2 \\
\leq C \left( \| \rho_\tau(\tau, \cdot) \|_2 + \| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2 + \varepsilon \| \rho_\tau(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2^2 \right.
$$

\[ + \varepsilon \| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2 + \varepsilon^2 \| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2^2 \right),
\]

(6.12)

for some positive constant $C$, depending on $\Phi$ but being independent of $\tau \in [0, T]$. Using Young inequality $ab \leq \frac{1}{4}a^2 + b^2$, we can estimate

$$
C\| \rho_\tau(\tau, \cdot) \|_2 \leq \frac{1}{4}\| \rho_\tau(\tau, \cdot) \|_2^2 + C^2,
$$

$$
C\| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2 \leq \frac{1}{4}\| \rho_{qy}(\tau, \cdot) \|_2^2 + C^2\| \rho_{qy}(\tau, \cdot) \|_2^2,
$$

$$
C\| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2 \leq \frac{1}{4}\| \rho_{qy}(\tau, \cdot) \|_2^2 + C^2\| \rho_{qy}(\tau, \cdot) \|_2^2,
$$

$$
C\| \rho_{qy}(\tau, \cdot) \|_2 \| \rho_{qy}(\tau, \cdot) \|_2 \leq \frac{1}{4}\| \rho_{qy}(\tau, \cdot) \|_2^2 + C^2\| \rho_{qy}(\tau, \cdot) \|_2^2,
$$

(6.13)

Hence, from (6.12) we get

$$
\frac{3}{2}(1 - \varepsilon) \frac{d}{d\tau} \| \rho_{qy}(\tau, \cdot) \|_2^2 + \| \rho_\tau(\tau, \cdot) \|_2^2 + 3\varepsilon \| \rho_{qy}(\tau, \cdot) \|_2^2 \\
\leq C^2 + \frac{3}{4}\| \rho_\tau(\tau, \cdot) \|_2^2 + \frac{1}{4}(\varepsilon + \varepsilon^2)\| \rho_{qy}(\tau, \cdot) \|_2^2
$$

\[ + C^2(1 + \varepsilon + \varepsilon^2)\| \rho_{qy}(\tau, \cdot) \|_2^2 + C^2\varepsilon^2\| \rho_{qy}(\tau, \cdot) \|_2^2, \]

(6.14)

or, equivalently,

$$
\frac{d}{d\tau} \| \rho_{qy}(\tau, \cdot) \|_2^2 \leq \frac{4}{3}C^2 + 4C^2\| \rho_{qy}(\tau, \cdot) \|_2^2 + \frac{4}{3}C^2\varepsilon^2\| \rho_{qy}(\tau, \cdot) \|_2^2
$$

\[ \leq \frac{4}{3}C^2 + 4C^2\| \rho_{qy}(\tau, \cdot) \|_2^2 + \frac{2}{3}C^2\varepsilon\| \rho_{qy}(\tau, \cdot) \|_2^2, \]

provided that $\varepsilon \leq 1/2$.

Applying Lemma 6.3 to (6.13) with $A_c(\tau) = \| \rho_{qy}(\tau, \cdot) \|_2^2$ and $(C_0, C_1, C_2) = (4C^2/3, 4C^2, 2C^2/3)$, we immediately deduce that there exist $\varepsilon_0 \in (0, 1/2)$ and $K_0 > 0$ such that

$$
\sup_{\tau \in (0, T)} \int_{\ell \over \varepsilon^2}^{\ell + 2\varepsilon^2} (\rho_{qy}(\tau, \eta))^2 d\eta \leq K_0,
$$

for any $\varepsilon \in (0, \varepsilon_0)$. Now, using a Poincaré-Wirtinger inequality, we get

$$
\sup_{\eta \in (-\varepsilon_0/2, \varepsilon_0/2)} | \rho_{qy}(\tau, \eta) | \leq K_1,
$$

for any $\varepsilon \in (0, \varepsilon_0]$, with $K_1$ independent of $\varepsilon$. 

Finally, integrating (3.13) and using the estimates so far obtained, we deduce that
\[ \int_0^T \int_{\frac{\epsilon_0}{2}}^{\frac{\epsilon_0}{2}} (\rho_\epsilon(\tau,\eta))^2 d\tau d\eta + \int_0^T \int_{\frac{\epsilon_0}{2}}^{\frac{\epsilon_0}{2}} (\rho_{\epsilon_0}(\tau,\eta))^2 d\tau d\eta \leq K_2, \]
for some constant \( K_2 \), independent of \( \epsilon \). The assertion now follows. \( \Box \)

**Corollary 6.7.** Under the assumptions of Theorem 5.4, there exists a constant \( M > 0 \) such that
\[ \|\rho\|_{C^{0,1}(0,T) \times [-\ell_0/2,\ell_0/2]} \leq M, \]
for any \( \epsilon \in (0, \epsilon_0] \).

**Proof.** In view of Theorem 6.1, we have only to estimate the sup-norm of the function \( \rho \). Since \( \rho \in \mathcal{B}_T \) and \( \rho(0,\cdot) = 0 \), we have
\[ \sup_{\tau \in [0,T]} |\rho(\tau,\eta)| \leq \int_0^T |\rho_\epsilon(\sigma,\eta)| d\sigma, \quad \eta \in [-\ell_0, \ell_0]. \]

Integrating both the sides of the previous inequality with respect to \( \eta \in [-\ell_0/2, \ell_0/2] \), we get
\[ \int_{-\frac{\epsilon_0}{2}}^{\frac{\epsilon_0}{2}} \sup_{\tau \in [0,T]} |\rho(\tau,\eta)| d\eta \leq \int_{-\frac{\epsilon_0}{2}}^{\frac{\epsilon_0}{2}} \int_0^T |\rho_\epsilon(\sigma,\eta)| d\sigma d\eta \leq \sqrt{\ell_0 T} \int_0^T d\sigma \int_{-\frac{\epsilon_0}{2}}^{\frac{\epsilon_0}{2}} |\rho_\epsilon(\sigma,\eta)|^2 d\eta \leq K \sqrt{\ell_0 T}, \]
where \( K \) is the constant in Theorem 6.1. Therefore, the function \( \rho \) remains in a bounded subset of the space \( L^1((-\ell_0/2,\ell_0/2); L^\infty(0,T)) \). Thanks to the uniform estimate on \( \rho_0 \) on \([0,T] \times [-\ell_0/2,\ell_0/2] \), we infer that \( \rho \) is bounded in \( W^{1,1}((-\ell_0/2,\ell_0/2); L^\infty(0,T)) \). Hence, by the Sobolev embedding, \( \rho \) is bounded in \([0,T] \times [-\ell_0/2,\ell_0/2] \). This accomplishes the proof. \( \Box \)

6.2. **Solving Equation (4.20) in \([0,T] \).** We now consider a fixed time interval \([0,T] \) and \( 0 < \epsilon \leq \epsilon_0 \), with \( \epsilon_0 = \epsilon_0(T) \) given by Theorem 6.1. Thanks to the a priori estimates of Subsection 6.1 and a classical result for semilinear problems, we can show that, for any \( \epsilon \in (0, \epsilon_0] \), the solution \( \rho = \rho_\epsilon \) to Problem (4.20), given by Theorem 5.6, can be extended with a function \( \rho \in \mathcal{B}_T \) (see Definition 4.1), which solves the equation in the whole of \([0,T] \).

**Theorem 6.8.** Fix \( T > 0 \) and let \( \epsilon_0 = \epsilon_0(T_0) \) be as in Theorem 6.1. Then, for any \( \epsilon \in (0, \epsilon_0] \), Equation (4.20) admits a unique solution \( \rho \in \mathcal{B}_T \).

**Proof.** Let us fix \( T \) as in the statement of the theorem and let \( \epsilon \in (0, \epsilon_0] \). Suppose by contradiction that \( T_\epsilon < T \). Then, by Theorem 6.4,
\[ \sup_{\tau \in [0,T_\epsilon]} \|\rho_\epsilon(\tau,\cdot)\|_{C^1([-\ell_0/2,\ell_0/2])} < K, \]
for some positive constant \( K \), independent of \( \epsilon \). Hence, the function \( \mathcal{H}_\epsilon(\cdot,\rho_\epsilon^2) \) is bounded in \([0,T_\epsilon] \times [-\ell_0/2,\ell_0/2] \). In view of [8, Prop. 7.1.8], applied to Equation (4.20), this leads us to a contradiction. \( \Box \)
6.3. Proof of Main Theorem. We are now in a position to prove the main result of this paper. Let us fix a function \( \Phi_0 \in C^{4+\beta} \) for some \( \beta \in (1/2, 1) \).

From the results in Subsection 5.2, we know that, for any \( T > 0 \), there exists \( \varepsilon_0 = \varepsilon_0(T) \) such that Equation (4.10) admits a unique solution \( \psi \in \mathcal{Y}_T \) (see Definition 4.1) such that \( \rho(0, \cdot) = \Phi_0 \). Moreover, by Corollary 5.3,

\[
\| \psi(\tau, \cdot) - \Phi_0(\tau, \cdot) \|_{C([-\varepsilon_0/2, \varepsilon_0/2])} \leq \varepsilon M, \quad \tau \in [0, T],
\]

for some positive constant \( M \) and any \( \varepsilon \in (0, \varepsilon_0] \).

In view of Theorem 4.3, there exists a (unique) function \( v \in \mathcal{Y}_T \) such that the pair \((v, \psi)\) is the unique solution to Problem (1.3)–(1.10).

Coming back to Problem (1.3)–(1.10) and setting \( \ell_\varepsilon = \ell_0/\varepsilon \) and \( T_\varepsilon = T/\varepsilon^2 \), it is now immediate to conclude that, for any \( \varepsilon \in (0, \varepsilon_0] \), it admits a unique solution \((u, \varphi)\) \( \in \mathcal{Y}_{T_\varepsilon} \times \mathcal{Y}_{T_\varepsilon} \). Moreover,

\[
\| \varphi(t, \cdot) - \varepsilon \Phi(te^2, \sqrt{\varepsilon} \cdot) \|_{C([-\ell_\varepsilon/2, \ell_\varepsilon/2])} \leq \varepsilon^2 M, \quad t \in [0, T_\varepsilon].
\]

This accomplishes the proof of Main Theorem.

Acknowledgments

J.H. and L.L. were visiting professors at the University of Bordeaux 1 respectively in 2006-2007 and 2007-2009. They greatly acknowledge the Institute of Mathematics of Bordeaux for the warm hospitality during their visits.

Appendix A. Some results from [4]

In this appendix we recall some results from [4] that are used throughout this paper.

A.1. The operator \( L \). Let \( \mathcal{L} \) be the differential operator defined on smooth (generalized) functions \( u \) by

\[
(\mathcal{L}u)(x, \eta) = \begin{cases} 
D_{xx}u(x, \eta) - D_xu(x, \eta) + \varepsilon u(0, \eta), & x \leq 0, \quad |\eta| \leq \frac{4\varepsilon}{5}, \\
D_{xx}u(x, \eta) - D_xu(x, \eta), & x \geq 0, \quad |\eta| \leq \frac{4\varepsilon}{5},
\end{cases}
\]

and let \( L \) be its the realization in \( \mathcal{X} \), defined by

\[
D(L) = \left\{ u \in C^{2,0}(I_-) \times C^{2,0}(I_+) : \mathcal{L}u \in \mathcal{X} \right\}
\]

\[
D_j^{(j)}u_1(0, \cdot) = D_j^{(j)}u_2(0, \cdot), \quad j = 0, 1,
\]

\[
Lu = \begin{cases} 
D_{xx}u_1 - D_xu_1 + u_1(0, \cdot)\varepsilon, & (x, \eta) \in I_- , \\
D_{xx}u_2 - D_xu_2, & (x, \eta) \in I_+.
\end{cases}
\]

Theorem A.1. The following properties are met:

(i) the operator \( L \) is sectorial and, hence, it generates an analytic semigroup in \( \mathcal{X} \);

(ii) the spectrum of the operator \( L \) consists of 0 and the halfline \( (-\infty, -1/4] \);

(iii) the spectral projection on the kernel of \( L \) is the operator \( \mathcal{P} \) defined by

\[
\mathcal{P}(f) = \left( \int_{-\infty}^0 f_1(x, \cdot)dx + \int_{0}^{+\infty} e^{-x}f_2(x, \cdot)dx \right) U := Q(f)U, \quad f \in \mathcal{X};
\]

(iv) let \( f \in \mathcal{X} \). Then, the equation \( Lu = f \) has a solution \( u \in D(L) \) if and only if \( \mathcal{P}(f) = 0 \).
A.2. The operator \( L_\varepsilon \). For any \( \varepsilon > 0 \), we consider the operator \( L + \varepsilon A \) defined by

\[
D(L + \varepsilon A) = \left\{ u \in \mathcal{D}(\mathcal{A}) : D^{(j)} u(0, \cdot) = 0, j = 0, 1, D^{(j)} u(\cdot, \cdot) \in \mathcal{D}^{(j)}(0, \cdot), \right. \\
\left. \mathcal{L}u \in \mathcal{D}, \mathcal{D}(\mathcal{A}) = \mathcal{D}(\mathcal{A}) \cap \mathcal{D}^{(j)}(0, \cdot), j = 0, 1, \mathcal{D}(\mathcal{A}) = \mathcal{D}(\mathcal{A}) \cap \mathcal{D}^{(j)}(0, \cdot), i = 1, 2, j = 0, 1 \right\},
\]

\[
(L + \varepsilon A)u = \begin{cases} 
D_x u + \varepsilon D_{\eta} u - D_x u + u(0, \cdot) e^\tau, & (x, y) \in I, \\
D_{x} u + \varepsilon D_{\eta} u - D_{x} u + u(0, \cdot) e^\tau, & (x, y) \in I.
\end{cases}
\]

**Theorem A.2.** The following properties are met.

(i) The operator \( L + \varepsilon A \) is closable and its closure \( L_\varepsilon \) is sectorial;
(ii) the restriction of \( L_\varepsilon \) to \( (I - \mathcal{A})(\mathcal{L}) \) is sectorial and 0 is in its resolvent set;
(iii) let \( f = h \varphi \) for some \( h \in (I - \mathcal{A})(\mathcal{L}) \), independent of \( y \), and some \( \varphi \in C^{2\alpha} \) \((\alpha \in (0, 1) \setminus \{1/2\}) \). Then, the function \( R(0, L_\varepsilon)f \) belongs to \( D(L + \varepsilon A) \).

Moreover, there exists a positive constant \( C \), depending on \( \varepsilon \) and \( \alpha \) but being independent of \( h \) and \( \varphi \), such that

\[
\|D^i_x R(0, L_\varepsilon)f\|_\mathcal{L} + \|D^i_\eta R(0, L_\varepsilon)f\|_\mathcal{L} \leq C\|h\|_\mathcal{L}\|\varphi\|_{C^{2\alpha}([-\ell_0/2, \ell_0/2])}, \quad (A.2)
\]

for \( i = 0, 1, 2 \).

A.3. Proof of Theorem 5.4. We split the proof into three steps. In the first one, we show that Problem (4.19) admits a unique solution \( \Phi \) in some time domain \([0, T_0]\). Since this result can be proved using the same arguments as in Subsection 5.3, we just sketch the proof. Then, in Steps 2 and 3, we show that \( \Phi \) exists and is smooth in the whole of \([0, +\infty)\).

**Step 1.** As we have already remarked in the proof of Proposition 5.4, the realization \( A \) of the second order derivative in \( C([-\ell_0/2, \ell_0/2]) \), with domain \( C^1([-\ell_0/2, \ell_0/2]) \), is a sectorial operator with spectrum contained in \((-\infty, 0)\). By Prop. 2.4.1 & 2.4.4 the operator \( B := -3A^2 - A \) is sectorial in \( C([-\ell_0/2, \ell_0/2]) \) with domain \( D(A^2) \). Moreover, \( D_B(\alpha, \infty) = C^2_\alpha \), with equivalence of the corresponding norms, for any \( \alpha \in (0, 2) \) such that \( 4\alpha \notin \mathbb{N} \).

The variation of constants formula shows that any solution \( \Phi \in C^{1,4}([0, +\infty) \times \mathbb{R}^N) \) to the Cauchy problem (4.19) is a fixed point of the operator \( \Gamma \), formally defined by

\[
(\Gamma(\Phi))(\tau, \cdot) = e^{\tau B} \Phi_0 + \int_0^\tau e^{(\tau-s)B}(\Phi_{\eta}(s, \cdot))\, ds, \quad \tau > 0,
\]

where \( \{e^{tB}\} \) denotes the semigroup generated by \( B \).
Let us fix $\alpha \in (1/4, 1/2)$. Theorem 7.1.2 in [1] implies that $\Gamma$ has a unique fixed point $\Phi$ in $C([0,T_0]; D_B(\alpha, \infty))$. A bootstrap argument allows to prove that $\Phi$ belongs to $Y_{T_0}$. Using [1, Prop. 4.2.1] and our assumptions on $\Phi_0$, it can be shown, first that $\Phi \in C^{4,\gamma}([0, T_0] \times [-\ell_0/2, \ell_0/2])$ for any $\gamma \in (0, 1)$, and then, that $\Phi_{\cdot t} \in C^{3}([0, T_0] \times [-\ell_0/2, \ell_0/2])$ for any $\beta \in (0, 3/4)$. Moreover, $D_{\eta}^{(j)}(\Phi(-\ell_0/2) = D_{\eta}^{(2)}(\Phi(-\ell_0/2)$ for $j = 0, 1, 2, 3$. Next, applying [3, Thm. 4.3.1(i)], we deduce that $\Phi \in C^{1,4}([0, T] \times [-\ell_0/2, \ell_0/2])$ and satisfies the boundary conditions $\Phi_{x}$ and its derivatives satisfy periodic boundary conditions, from which Estimate (A.3) follows at once.

For this purpose, we fix $\tau$ vanishes for any $\eta$. Since $\Phi$ and its derivatives satisfy periodic boundary conditions, $\Phi_{\cdot x}$ is in $D_{\eta}^{(j)}([0, T_0] \times [-\ell_0/2, \ell_0/2])$ as well, and $D_{\eta}^{(j)}(\Phi(-\ell_0/2) = D_{\eta}^{(2)}(\Phi(-\ell_0/2)$ for $j = 4, 5, 6$.

Using a continuation argument, we can extend $\Phi$ to a maximal domain $[0, T)$ with a function (still denoted by $\Phi$) which belongs to $Y_{T}$, for any $T' < T$.

The rest of the proof is devoted to show that $T = +\infty$. The main step is an a priori estimate suggested by the proof [2, Thm. 2.4], which deals with $L^2$ regularity for the K–S equation.

**Step 2.** Here, we show that

$$\|\Phi_{\cdot x}(\tau, \cdot)\|_2 \leq (\Phi_{\cdot x}^{(4)})^\tau ||D_{\eta}^{4}\Phi_{0}||_2, \quad \tau \in [0, T).$$

(A.3)

For this purpose, we introduce the function $v$, defined by $v(\tau, \eta) = e^{-2\tau}\Phi_{\cdot x}(\tau, \eta)$ for any $\tau, \eta \in [0, T) \times [-\ell_0/2, \ell_0/2]$. The smoothness of $\Phi$ implies that $v \in C^{1,4}([0, T] \times [-\ell_0/2, \ell_0/2])$, solves the parabolic equation

$$v_{\tau} = -3v_{\eta\eta\eta\eta} - v_{\eta\eta} - e^{2\tau}v_{\eta\eta} - 2v,$$

(A.4)

and satisfies the boundary conditions $D_{\eta}^{(j)}(v(\tau, -\ell_0/2) = D_{\eta}^{(j)}(v(\tau, \ell_0/2) for any $v \in [0, T]$ and $k = 0, 1, 2, 3$. Multiplying both the sides of (A.4) by $v(\tau, \cdot)$, integrating on $(-\ell_0/2, \ell_0/2)$ and observing that the integral over $(-\ell_0/2, \ell_0/2)$ of $(v(\tau, \cdot)^2v_{\eta}(\tau, \cdot)$ vanishes for any $\tau \in [0, T]$, we get

$$\frac{d}{d\tau}\|v(\tau, \cdot)\|_2^2 + 3\|v_{\eta\eta}(\tau, \cdot)\|_2^2 - \|v_{\eta}(\tau, \cdot)\|_2^2 + 2\|v(\tau, \cdot)\|_2^2 = 0, \quad \tau \in [0, T).$$

(A.5)

In view of the estimate

$$\|v_{\eta\eta}(\tau, \cdot)\|_2^2 \leq \|v(\tau, \cdot)\|_2^2 \|v_{\eta\eta}(\tau, \cdot)\|_2 \leq 3\|v_{\eta\eta}(\tau, \cdot)\|_2^2 + \frac{5}{3}\|v(\tau, \cdot)\|_2^2, \quad \tau \in [0, T),$$

Formula (A.5) leads us to the inequality

$$\frac{d}{d\tau}\|v(\tau, \cdot)\|_2^2 + \frac{1}{3}\|v(\tau, \cdot)\|_2^2 \leq 0, \quad \tau \in [0, T),$$

from which Estimate (A.3) follows at once.

**Step 3.** Let us consider the function $\Phi$, defined by $\Phi(\tau, \eta) = \Phi(\tau, \eta) - \Pi(\Phi(\tau, \cdot))$ for any $\tau \in [0, T]$ and any $\eta \in [-\ell_0/2, \ell_0/2]$, where $\Pi(\Phi(\tau, \cdot))$ denotes the average of $\Phi(\tau, \cdot)$ over the interval $(-\ell_0/2, \ell_0/2)$. Applying Poincaré-Wirtinger inequality, we get

$$\|\Phi(\tau, \cdot) - \Pi(\Phi(\tau, \cdot))\|_\infty \leq \sqrt{6_0e^{2\tau}}||D_{\eta}\Phi_{0}||_2, \quad \tau \in [0, T).$$

(A.6)

Let us now show that the function $\tau \mapsto \Pi(\Phi(\tau, \cdot))$ satisfies a similar estimate. For this purpose, we fix $T' \in (0, T)$, $\tau \in [0, T')$, and apply the operator $\Pi$ to both the sides of (A.1). Since $\Phi$ and its derivatives satisfy periodic boundary conditions,

$$\frac{d}{d\tau}\Pi(\Phi(\tau, \cdot)) = \Pi(\Phi(\tau, \cdot)) = -\frac{1}{2\ell_0}\Pi((\Phi_{\cdot x}(\tau, \cdot))^2),$$

(A.7)
for any $\tau \in [0, T)$. Taking (A.3) into account, we can then estimate
\begin{align*}
\left| \frac{d}{d\tau} \Pi(\Phi(\tau, \cdot)) \right| & \leq \frac{1}{2\ell_0} \| D_\eta \Phi_0 \|_2^2, \quad \tau \in [0, T).
\end{align*}

Hence,
\begin{align*}
\Pi(\Phi(\tau)) & \leq |\Pi(\Phi_0)| + \int_0^\tau \left| \frac{d}{d\tau} \Pi(\Phi(\tau, \cdot)) \right| d\tau \\
& \leq |\Pi(\Phi_0)| + \frac{3}{26\ell_0} \| D_\eta \Phi_0 \|_2^2 e^{\frac{26}{\ell_0} \tau}, \quad (A.7)
\end{align*}
for any $\tau \in [0, T)$. Estimates (A.6) and (A.7) show that $\Phi$ is bounded in $[0, T) \times [-\ell_0/2, \ell_0/2]$. Therefore, we can apply [9, Prop. 7.2.2] with $X_\alpha = D_B(\alpha, \infty)$, which implies that $T = +\infty$.
