Abstract. We deal with the mathematical analysis of the coupling problem in a bounded domain of \mathbb{R}^n , $n \geq 1$, between a purely quasilinear first-order hyperbolic equation set on a subdomain and a parabolic one, set on its complementary. We start by providing the definition of a weak solution through an entropy inequality on the whole domain. The uniqueness property relies on a pointwise inequality along the interface between the two subdomains and on the method of doubling variables. The existence proof is based on a vanishing viscosity method.

1 Introduction

1.1 Presentation

Let Ω be a bounded domain of \mathbb{R}^n with a Lipschitz boundary $\Gamma = \partial\Omega$, $n \geq 1$, such that $\bar{\Omega} = \bar{\Omega}_h \cup \bar{\Omega}_p$. We suppose that Ω_h (the hyperbolic zone) and Ω_p (the parabolic one) are two disjoint bounded domains with Lipschitz boundaries $\Gamma_l \equiv \partial\Omega_l$, $l \in \{h, p\}$. We denote the interface by $\Gamma_{hp} = \Gamma_h \cap \Gamma_p$ and assume that for l in $\{h, p\}$, the set $(\bar{\Gamma}_{hp} \cap (\bar{\Gamma}_l \setminus \Gamma_{hp}))$ has a zero \mathcal{H}^{n-1} -measure. Let T be a finite positive real number: we are interested in the uniqueness and existence of a measurable and bounded function u on $Q \equiv (0, T) \times \Omega$ satisfying (at least in a distributional sense)

$$\begin{cases} \partial_t u + \operatorname{div}_x(b(x)\mathbf{f}(u)) + g(t, x, u) &= \operatorname{div}_x(\mathbb{I}_{\Omega_p}(x)\nabla\phi(u)) & \text{in } Q, \\ u &= 0 & \text{on } \Sigma \equiv (0, T) \times \Gamma, \\ u(0, \cdot) &= u_0 & \text{on } \Omega, \end{cases} \quad (1)$$

for discontinuous fluxes and reaction terms given by:

$$\begin{aligned} b(x)\mathbf{f}(u) &= b_h(x)\mathbf{f}_h(u)\mathbb{I}_{\Omega_h} + b_p(x)\mathbf{f}_p(u)\mathbb{I}_{\Omega_p}, \\ g(t, x, u) &= g_p(t, x, u)\mathbb{I}_{\Omega_p}(x) + g_h(t, x, u)\mathbb{I}_{\Omega_h}(x). \end{aligned}$$

Here for each set $A \subset \Omega$, $\mathbb{I}_A(x) = \begin{cases} 1 & \text{if } x \in A, \\ 0 & \text{else.} \end{cases}$

With these notations, the equation in (1) is reduced to the hyperbolic first-order equation

$$\partial_t u + \operatorname{div}_x(b_h(x)\mathbf{f}_h(u)) + g_h(t, x, u) = 0 \text{ in } Q_h \equiv (0, T) \times \Omega_h,$$

and to the parabolic one

$$\partial_t u + \operatorname{div}_x(b_p(x)\mathbf{f}_p(u)) + g_p(t, x, u) = \Delta\phi(u) \text{ in } Q_p \equiv (0, T) \times \Omega_p.$$

Furthermore it implicitly contains the (*formal*) transmission condition along the interface:

$$(b_p\mathbf{f}_p(u) - b_h\mathbf{f}_h(u)) \cdot \nu_h = \nabla\phi(u) \cdot \nu_h \text{ on } \Sigma_{hp}. \quad (2)$$

As mentioned in [6], this type of problem arises from several physical applications that are modelled by a global advection-diffusion-reaction in the whole Ω . However, in these problems, the diffusive term may be relevant only in a subregion Ω_p (which clearly depends on the problem in hands) while it can be neglected in the rest of the domain Ω , without affecting the solution in a sensible way.

Fluid dynamics is among the field that benefit largely from a coupling approach of the type considered here. For example, we may consider viscous-compressible flows around a rigid profile (*e.g.* an aerofoil). Physical evidence suggests that viscosity effects are negligible apart from a small region close to the rigid body. So that the mathematical modelling of the problem may lead to use equations with different character (precisely Euler, Navier-Stokes equations) in separate regions, by dropping viscous terms when they are very small.

Another example is provided by a heat transfer problem such as a forced incompressible flow over a heated plate. In such a case, the thermal diffusivity is much more important in the boundary layer than elsewhere (here the reduced equation of conservation of energy can be assumed to describe the flows field). The velocity field can be evaluated independently from the temperature while the latter is the solution to an advection-diffusion equation in which the transport field is given precisely by the (known) velocity. Away from the boundary layer, the diffusive term may be neglected.

We complete this introduction with a last example, within the framework of infiltration processes through a stratified subsoil viewed as an heterogeneous porous medium with different geological characteristics in each layer, and such that, depending of the physical properties of the rocks, the diffusivity effects may be neglected with respect to the transport ones. This approach has mainly motivated the previous studies in [1],[2], and [7].

1.2 Notations and main assumptions on data

Throughout this paper, we give by a subscript h when referring to the hyperbolic zone and a subscript p for the parabolic one. Then, for $l \in \{h, p\}$,

- the coefficients b_l are elements of $W^{2,\infty}(\Omega_l)$ and the vector flux function $\mathbf{f}_l = (f_{l,1}, \dots, f_{l,n})$ belongs to $W^{2,\infty}(\mathbb{R})^n$. For $i = 1, \dots, n$, the positive real M_{f_i} denotes the Lipschitz constant of f_i and set $M_{\mathbf{f}} = \max_{i=1, \dots, n} M_{f_i}$,
- the source term g_l is in $W^{1,\infty}([0, T] \times \Omega_l \times \mathbb{R})$, such that

$$\exists M_{g_l} \in \mathbb{R}^+, \text{ a.e. on }]0, T[\times \Omega_l \times \mathbb{R}, |\partial_u g_l| \leq M_{g_l}.$$

We set $M_g = M_{g_h} + M_{g_p}$.

- the diffusion term ϕ is an increasing function of $W^{1,\infty}(\mathbb{R})$. By normalization, we suppose that $\phi(0) = 0$. In addition, we assume that ϕ^{-1} exists on $\operatorname{Im}(\phi)$. That means that the second order operator set on the parabolic area is *weakly degenerated*. This is in particular fulfilled when $\{x \in \mathbb{R}, \phi'(x) = 0\}$ has a zero Lebesgue measure.
- in order to deal with bounded solutions, the initial datum u_0 belongs to $L^\infty(\Omega)$ and takes values in $[m, M]$ where m and M are two fixed real numbers and we introduce a nondecreasing smooth function M_1 of the time variable and a nonincreasing smooth function M_2 of the time variable such that

$$\begin{cases} M_1(0) \geq M, \\ \forall t \in (0, T) \\ M_1'(t) + \nabla b(\cdot) \cdot \mathbf{f}(M_1(t)) + g(t, \cdot, M_1(t)) \geq 0 \text{ a.e. on } \Omega_L \cup \Omega_R, \end{cases}$$

and

$$\begin{cases} M_2(0) \leq m, \\ \forall t \in (0, T) \\ M_2'(t) + \nabla b(\cdot) \cdot \mathbf{f}(M_2(t)) + g(t, \cdot, M_2(t)) \leq 0 \text{ a.e. on } \Omega_L \cup \Omega_R. \end{cases}$$

Observe that one can propose

$$M_1 : t \in [0, T] \longrightarrow M_1(t) = \operatorname{ess\,sup}_{\Omega} u_0^+ e^{N_1 t} + \frac{N_2}{N_1} (e^{N_1 t} - 1),$$

and

$$M_2 : t \in [0, T] \longrightarrow M_2(t) = \operatorname{ess\,inf}_{\Omega} (-u_0^-) e^{N_1 t} - \frac{N_2}{N_1} (e^{N_1 t} - 1),$$

with

$$N_1 = \max(\|\nabla b_h\|_{L^\infty(\Omega_h)^n}, \|\nabla b_p\|_{L^\infty(\Omega_p)^n}) \sum_{i=1}^n M_{f_i} + M_g,$$

$$\text{and } N_2 = \sum_{l=h,p} \max_{[0,T] \times \bar{\Omega}} |g(t, x, 0) + \nabla b_l(x) \cdot \mathbf{f}(0)|.$$

- Since $\Gamma_p \setminus \Gamma_{hp}$ has a non zero \mathcal{H}^{n-1} -measure we may consider the Hilbert space

$$V = \{v \in H^1(\Omega_p), v = 0 \text{ a.e. on } \Gamma_p \setminus \Gamma_{hp}\},$$

endowed with the norm $\|v\|_V = \|\nabla v\|_{L^2(\Omega_p)^n}$, which is equivalent to the classical $H^1(\Omega_p)$ -norm. Then we denote $\langle \langle \cdot, \cdot \rangle \rangle$ the duality pairing between V and V' .

- The notation $|\cdot|_n$ stands for the Euclidian norm on \mathbb{R}^n .
- For any real numbers a, b , we set $I(a, b)$ is the closed interval bounded by a and b .
- The function sgn_η stands for the Lipschitzian approximation of the function sgn given for any positive η and any nonnegative real number x by $sgn_\eta(x) = \min(\frac{x}{\eta}, 1)$ and $sgn_\eta(-x) = -sgn_\eta(x)$. Lastly, for any real numbers τ, k , we introduce the *classical* Otto flux [9, 10] which is now a standard and useful tool to transcript - through an integral inequality - the boundary condition along the hyperbolic frontier (see (5) below)

$$\mathcal{F}_h(\tau, k) = \frac{1}{2} \{sgn(\tau)(\mathbf{f}_h(\tau) - \mathbf{f}_h(0)) - sgn(k)(\mathbf{f}_h(k) - \mathbf{f}_h(0)) + sgn(\tau - k)(\mathbf{f}_h(\tau) - \mathbf{f}_h(k))\}.$$

This paper is organized as follows. In Section 2 we give the definition of a weak entropy solution to (1). We show in Section 3 the uniqueness of such a solution while Section 4 is mainly devoted to the proof of the existence property, by the vanishing viscosity method.

2 A notion of weak entropy solution

We want to take into account not only the coexistence of known hyperbolic and parabolic areas in the studied field but also the unknown ones in Ω_p coming from the degeneracy of the second order operator set in Ω_p . With this view we define a weak solution to (1) through a global entropy inequality on the whole domain Q in the same spirit as in [7].

To this end we introduce the next mollified entropy pairs:

$$I_\eta(a, b) = \int_b^a sgn_\eta(\phi(\tau) - \phi(b)) d\tau$$

and

$$\mathbf{F}_{l,\eta}(a, b) = \int_{\phi(b)}^{\phi(a)} \mathbf{f}_l \circ \phi^{-1}(\tau) sgn'_\eta(\tau - \phi(b)) d\tau.$$

Moreover we set $\mathbf{F}_\eta = \mathbf{F}_{h,\eta} \mathbb{1}_{\Omega_h} + \mathbf{F}_{p,\eta} \mathbb{1}_{\Omega_p}$. Then it will be said that

Definition 1. A measurable function u on Q is a weak entropy solution to (1) if
(i) $u \in L^\infty(Q)$, $\phi(u) \in L^2(0, T; V)$,
(ii) $\forall \varphi \in \mathcal{D}(Q)$ with $\varphi \geq 0$, $\forall k \in \mathbb{R}$,

$$\begin{aligned} & \int_Q I_\eta(u, k) \partial_t \varphi dx dt - \int_Q \text{sgn}_\eta(\phi(u) - \phi(k)) \nabla \phi(u) \cdot \nabla \varphi dx dt \\ & + \int_Q b(x) \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}(u) - \mathbf{F}_\eta(u, k) \} \cdot \nabla \varphi dx dt \\ & - \int_Q \{ \text{sgn}_\eta(\phi(u) - \phi(k)) g(t, x, u) + \nabla b(x) \cdot \mathbf{F}_\eta(u, k) \} \varphi dx dt \\ & + \int_{\Sigma_{hp}} (b_h(\bar{\sigma}) \mathbf{F}_{h,\eta}(u, k) - b_p(\bar{\sigma}) \mathbf{F}_{p,\eta}(u, k)) \varphi \cdot \boldsymbol{\nu}_h dt d\mathcal{H}_\sigma^{n-1} \geq 0 \end{aligned} \quad (3)$$

(iii) u satisfies the initial condition in the L^1 -sense i.e.

$$\text{ess lim}_{t \rightarrow 0^+} \int_\Omega |u(t, x) - u_0(x)| dx = 0. \quad (4)$$

(iv) For any ζ in $L^1(\Sigma_h \setminus \Sigma_{hp})$, $\zeta \geq 0$, $\forall k \in \mathbb{R}$,

$$\text{ess lim}_{s \rightarrow 0^-} \int_{\Sigma_{hp}} b(\bar{\sigma}) \mathcal{F}_h(u(\sigma + s \boldsymbol{\nu}_h), k) \cdot \boldsymbol{\nu}_h dt d\mathcal{H}_\sigma^{n-1} \geq 0, \quad (5)$$

where $\sigma = (t, \bar{\sigma}) \in \Sigma$.

Entropy inequality (3) is expressed with a mollification of the classical Kruzhkov entropy pairs. This will be used in Lemma 2 to transcript an entropy jump condition across the interface Σ_{hp} for a weak entropy solution. This regularization was not needed in [7], where the characteristics along Σ_{hp} were known so that this jump condition was automatically fulfilled. This is the main feature and contribution of this work in comparison with the previous ones [1, 2, 7]

Remark 1. When we take the limit with respect to η in (3), since for $l = h, p$,

$$\lim_{\eta \rightarrow 0^+} \mathbf{F}_{l,\eta}(u, k) = \text{sgn}(\phi(u) - \phi(k)) \mathbf{f}_l(k) = \text{sgn}(u - k) \mathbf{f}_l(k),$$

ϕ being nondecreasing, we obtain an entropy inequality written with the standard Kruzhkov entropy pairs

$$\begin{aligned} & \int_Q |u - k| \partial_t \varphi dx dt - \int_Q \nabla |\phi(u) - \phi(k)| \cdot \nabla \varphi dx dt \\ & + \int_Q b(x) \Phi(u, k) \cdot \nabla \varphi dx dt \\ & - \int_Q \text{sgn}(u - k) (g(t, x, u) + \nabla b(x) \cdot \mathbf{f}(k)) \varphi dx dt \\ & + \int_{\Sigma_{hp}} \text{sgn}(\phi(u) - \phi(k)) (b_h \mathbf{f}_h(k) - b_p \mathbf{f}_p(k)) \cdot \boldsymbol{\nu}_h \varphi dt d\mathcal{H}^{n-1} \geq 0 \end{aligned} \quad (6)$$

where $\Phi(u, k) = \text{sgn}(u - k) (\mathbf{f}(u) - \mathbf{f}(k))$ is the Kruzhkov flux.

Remark 2. If u is a weak entropy solution then u is a solution to (1) in the sense of distributions, that is to say, for all $\varphi \in \mathcal{D}(Q)$,

$$\int_Q (u \partial_t \varphi + (b(x) \mathbf{f}(u) - \mathbb{I}_{\Omega_p} \nabla \phi(u)) \cdot \nabla \varphi - g(t, x, u) \varphi) dx dt = 0, \quad (7)$$

so that u fulfills

$$\begin{aligned} \partial_t u + \text{div}_x (b_h(x) \mathbf{f}_h(u)) + g_h(t, x, u) &= 0 \text{ in } \mathcal{D}'(Q_h), \\ \partial_t u + \text{div}_x (b_p(x) \mathbf{f}_p(u)) + g_p(t, x, u) &= \Delta \phi(u) \text{ in } \mathcal{D}'(Q_p). \end{aligned}$$

and the transmission condition (2) in a formal sense at this stage.

3 The uniqueness property

Our aim is to establish a time-Lipschitzian dependence in $L^1(\Omega)$ of a weak entropy solution u to (1) with respect to its corresponding initial datum. The idea of the proof is to derive from (3) two local formulations, one in Q_h and one in Q_p and an entropy jump condition along the interface Σ_{hp} . To transcript the latter, we need to define, in a certain way, a trace for u coming from the hyperbolic zone. Observe that a trace for u coming from the parabolic zone is given by the trace of $\phi(u)$ that belongs to $L^2(0, T; H^{1/2}(\Gamma_p))$. So we assume now that the flux function satisfies a non-degeneracy condition i.e. for almost all $x \in \Omega_h$, for all $\xi \in \mathbb{R}^n$ with $\xi \neq 0$, the function

$$\lambda \longmapsto \xi \cdot b_h(x) \mathbf{f}_h(\lambda) \text{ is not linear on any nondegenerated interval} \quad (8)$$

included in $[M_2(T), M_1(T)]$.

Assumption (8) will allow us to define *strong traces* as explained in Section 2 (see Lemma 1). Indeed, following the works of E. Yu. Panov [12] or A. Vasseur [15], it comes:

Lemma 1. *Let u be a function of $L^\infty(Q)$ satisfying (3). Under (8) there exists a function u^τ of $L^\infty(\Sigma_h)$ such that, for every compact K of Σ_h and every regular Lipschitz deformation Ψ of Ω_h ,*

$$\text{ess} \lim_{s \rightarrow 0^+} \int_K |u(\Psi(s, \sigma)) - u^\tau(\sigma)| dt d\mathcal{H}^{n-1} = 0. \quad (9)$$

Let us note that a regular Lipschitz deformation can be defined if Ω_h is, for example, a star-shaped domain (see [4] for more details).

In this framework, the boundary condition (5) on the outer frontier of the hyperbolic zone is written for almost all $t \in (0, T)$, \mathcal{H}^{n-1} -a.e. on $\Gamma_h \setminus \Gamma_{hp}$, $\forall k \in \mathbb{R}$,

$$b_h \mathcal{F}_h(u^\tau, k) \cdot \nu_h \geq 0, \quad (10)$$

which is equivalent to the well-known pointwise Bardos, LeRoux and Nédélec formulation given in [3].

To begin with, let us highlight some local informations included in inequality (3). Indeed, it first contains an entropy formulation on the hyperbolic domain since,

Proposition 1. *Let u be a weak entropy solution to (1). Then for any real number k and any $\varphi \in \mathcal{D}((0, T) \times \mathbb{R}^n)$ with $\varphi \geq 0$,*

$$\begin{aligned} & \int_{Q_h} |u - k| \partial_t \varphi dx dt + \int_{Q_h} b_h(x) \Phi_h(u, k) \cdot \nabla \varphi dx dt - \int_{Q_h} G_h(u, k) \varphi dx dt \\ & \geq \int_{\Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(u^\tau, k) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} + \int_{\Sigma_h \setminus \Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(0, k) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} \\ & - \int_{\Sigma_h \setminus \Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(u^\tau, 0) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} \end{aligned} \quad (11)$$

where

$$G_h(u, k) = \text{sgn}(u - k)(g_h(t, x, u) + \nabla b_h(x) \cdot \mathbf{f}_h(k))$$

and

$$\Phi_h(a, b) = \text{sgn}(u - k)(\mathbf{f}_h(a) - \mathbf{f}_h(b))$$

Proof. Thanks to Remark 1, we have for any $\varphi \in \mathcal{D}(Q_h)$ with $\varphi \geq 0$,

$$\int_{Q_h} (|u - k| \partial_t \varphi + b_h(x) \Phi_h(u, k) \cdot \nabla \varphi - G_h(u, k) \varphi) dx dt \geq 0. \quad (12)$$

Let $(\omega_\varepsilon)_{\varepsilon>0}$ be a sequence of functions such that for every ε , $\omega_\varepsilon \in \mathcal{C}^\infty(\overline{\Omega}_h)$ and

$$\begin{cases} 0 \leq \omega_\varepsilon \leq 1 \text{ on } \Omega_h, \\ \omega_\varepsilon(x) = 1 \text{ if } x \in \Gamma_h, \\ \omega_\varepsilon(x) = 0 \text{ if } d(x, \Gamma_h) > \varepsilon, \\ (\varepsilon \nabla \omega_\varepsilon)_\varepsilon \text{ is bounded on } \Omega_h. \end{cases}$$

We choose in (12) the test function $\varphi(1 - \omega_\varepsilon)$ and we take the limit with respect to ε . From the non-degeneracy condition (8) and Lemma 1, it comes

$$\lim_{\varepsilon \rightarrow 0^+} \int_{Q_h} b_h(x) \Phi_h(u, k) \cdot \nabla \omega_\varepsilon \varphi dx dt = \int_{\Sigma_h} b_h(\bar{\sigma}) \Phi_h(u^\tau, k) \cdot \nu_h dt d\mathcal{H}^{n-1}.$$

Thus

$$\begin{aligned} & \int_{Q_h} (|u - k| \partial_t \varphi + b_h(x) \Phi_h(u, k) \cdot \nabla \varphi - G_h(u, k) \varphi) dx dt \\ & \geq \int_{\Sigma_h} b_h(\bar{\sigma}) \Phi_h(u^\tau, k) \cdot \nu_h dt d\mathcal{H}^{n-1}. \end{aligned}$$

We split the frontier of Q_h into Σ_h and $\Sigma_h \setminus \Sigma_{hp}$. The boundary condition (10) provides

$$\begin{aligned} \int_{\Sigma_h \setminus \Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(u^\tau, k) \cdot \nu_h dt d\mathcal{H}^{n-1} & \geq \int_{\Sigma_h \setminus \Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(0, k) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} \\ & - \int_{\Sigma_h \setminus \Sigma_{hp}} b_h(\bar{\sigma}) \Phi_h(u^\tau, k) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} \end{aligned}$$

The conclusion follows. \square

Entropy inequality (11) is not sufficient to prove the uniqueness on the hyperbolic area: as stated forward in (19), it only provides an $L^1(Q_h)$ -error between two solutions with respect to their interface values and initial data. That is why we are interested now in the behavior of a weak entropy solution u to (1) on the parabolic zone. We prove that it fulfills a local variational equality that involves entering data from the hyperbolic domain:

Proposition 2. *Let u be a weak entropy solution to (1). Then $\partial_t u$ belongs to $L^2(0, T; V')$. Moreover, for any $\varphi \in L^2(0, T; V)$,*

$$\begin{aligned} & \int_0^T \langle \partial_t u, \varphi \rangle dt + \int_{Q_p} (\nabla \phi(u) - b_p \mathbf{f}_p(u)) \cdot \nabla \varphi dx dt \\ & + \int_{Q_p} g_p(t, x, u) \varphi dx dt - \int_{\Sigma_{hp}} b_h \mathbf{f}_h(u^\tau) \cdot \nu_h \varphi dt d\mathcal{H}^{n-1} = 0. \end{aligned} \quad (13)$$

Proof. We sketch this proof, the reasoning being the same as in [7]. By a density argument (7) is still true for any function φ of $\mathcal{D}(0, T; H_0^1(\Omega))$. Let $\xi \in \mathcal{D}(0, T; V)$ and $\hat{\xi}$ an extension of ξ to $\mathcal{D}(0, T; H_0^1(\Omega))$. We choose in (7) the test function $\varphi = \hat{\xi} \lambda_\varepsilon$ with, for any positive constant ε , $\lambda_\varepsilon \in \mathcal{C}^\infty(\overline{\Omega}_p)$ such that

$$\begin{cases} \lambda_\varepsilon(x) = 1 \text{ if } x \in \overline{\Omega}_p, \\ \lambda_\varepsilon(x) = 0 \text{ if } x \in \Omega_h, d(x, \Gamma_{hp}) \geq \varepsilon, \\ \|\varepsilon \nabla \lambda_\varepsilon\|_\infty \text{ is bounded.} \end{cases}$$

Then we take the limit with respect to ε in (7). Thanks to (8) and (9) we assert that

$$\lim_{\varepsilon \rightarrow 0^+} \int_{Q_h} b_h(x) \hat{\xi} \mathbf{f}_h(u) \cdot \nabla \lambda_\varepsilon dx dt = \int_{\Sigma_{hp}} b_h \mathbf{f}_h(u^\tau) \cdot \nu_h \xi dt d\mathcal{H}^{n-1},$$

and that provides (13). \square

Now we give a consequence of Proposition 2 where we may recognize a certain form of the relation (2) and that will be helpful to express the transmission condition along Σ_{hp} . To this purpose we introduce a sequence of $\mathcal{D}(\bar{\Omega})$, denoted by $(\beta_\varepsilon)_{\varepsilon>0}$, such that

$$\begin{cases} \forall \varepsilon > 0, 0 \leq \beta_\varepsilon \leq 1, \beta_\varepsilon = 1 \text{ if } x \in \Gamma_{hp}, \\ \forall \varepsilon > 0, \beta_\varepsilon = 0 \text{ if } x \in \Omega, d(x, \Gamma_{hp}) \geq \varepsilon, \\ \|\varepsilon \nabla \beta_\varepsilon\|_\infty \text{ is bounded,} \\ \forall x \in \Omega \setminus \Gamma_{hp}, \lim_{\varepsilon \rightarrow 0^+} \beta_\varepsilon(x) = 0. \end{cases} \quad (14)$$

Then we have

Lemma 2. *Let u in $L^\infty(Q)$ satisfying (13). Then for any ψ of $H_0^1(Q)$,*

$$\begin{aligned} & \lim_{\varepsilon \rightarrow 0^+} \int_{Q_p} \text{sgn}_\eta(\phi(u) - \phi(k)) \psi \nabla \phi(u) \cdot \nabla \beta_\varepsilon dx dt = \\ & \int_{\Sigma_{hp}} (b_h \mathbf{f}_h(u^\tau) - b_p \mathbf{f}_p(u^\phi)) \cdot \boldsymbol{\nu}_h \text{sgn}_\eta(\phi(u) - \phi(k)) \psi dt d\mathcal{H}^{n-1}, \end{aligned}$$

where $u^\phi = \phi^{-1}(\phi(u)|_{\Sigma_{hp}})$.

Proof. From Proposition 2 it comes for any φ of $L^2(0, T; V)$:

$$\begin{aligned} & \int_0^T \langle \langle \partial_t u, \varphi \beta_\varepsilon \rangle \rangle dt + \int_{Q_p} (\nabla \phi(u) - b_p \mathbf{f}_p(u)) \cdot \nabla \varphi \beta_\varepsilon dx dt + \int_{Q_p} g_p(t, x, u) \varphi \beta_\varepsilon dx dt \\ & + \int_{Q_p} (\nabla \phi(u) - b_p \mathbf{f}_p(u)) \cdot \nabla \beta_\varepsilon \varphi dx dt - \int_{\Sigma_{hp}} b_h \mathbf{f}_h(u^\tau) \cdot \boldsymbol{\nu}_h \varphi dt d\mathcal{H}^{n-1} = 0. \end{aligned}$$

We choose the test function $\varphi = \text{sgn}_\eta(\phi(u) - \phi(k)) \psi|_{Q_p}$, where $\psi \in \mathcal{D}(Q)$, $\psi \geq 0$. We use the F.Mignot time-integration by parts formula (see [5], p.31) to state:

$$\int_0^T \langle \langle \partial_t u, \varphi \beta_\varepsilon \rangle \rangle dt = - \int_{Q_p} I_\eta(u, k) \beta_\varepsilon \partial_t \psi dx dt.$$

Therefore,

$$\lim_{\varepsilon \rightarrow 0^+} \int_0^T \langle \langle \partial_t u, \varphi \beta_\varepsilon \rangle \rangle dt = 0.$$

Since $\mathbf{f}_p(u) = \mathbf{f}_p \circ \phi^{-1}(\phi(u))$ and $\mathbf{f}_p \circ \phi^{-1}$ is continuous, we claim that:

$$\lim_{\varepsilon \rightarrow 0^+} \int_{Q_p} b_p \mathbf{f}_p(u) \cdot \nabla \beta_\varepsilon \varphi dx dt = - \int_{\Sigma_{hp}} b_p \mathbf{f}(u^\phi) \text{sgn}_\eta(\phi(u) - \phi(k)) \cdot \boldsymbol{\nu}_h \psi dx dt$$

Thus

$$\begin{aligned} & \lim_{\varepsilon \rightarrow 0^+} \int_{Q_p} \nabla \phi(u) \cdot \nabla \beta_\varepsilon \text{sgn}_\eta(\phi(u) - \phi(k)) \psi dx dt \\ & = \int_{\Sigma_{hp}} (b_h \mathbf{f}_h(u^\tau) - b_p \mathbf{f}_p(u^\phi)) \cdot \boldsymbol{\nu}_h \text{sgn}_\eta(\phi(u) - \phi(k)) \psi dt d\mathcal{H}^{n-1}. \end{aligned}$$

That completes the proof. \square

Lemma 2 allows us to write a transmission condition along Σ_{hp} that is in fact included in the global formulation (3) on the whole Q . This is a key point of the uniqueness proof. Observe that this interface relation is written as a pointwise inequality on Σ_{hp} that requires the knowledge of strong traces coming from the hyperbolic area and from the parabolic one for a weak entropy solution to (1). Indeed the next entropy jump condition holds:

Lemma 3. *Let u be a weak entropy solution to (1). Then a.e. in $(0, T)$, \mathcal{H}^{n-1} -a.e. on Γ_{hp} , for any $k \in I(u^\tau, u^\phi)$,*

$$\text{sgn}(u^\tau - u^\phi) b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(k)) \cdot \boldsymbol{\nu}_h \geq 0. \quad (15)$$

Proof. For any real number $\varepsilon > 0$, we consider in (3) the test function $\varphi_\varepsilon = \psi \beta_\varepsilon$ with $\psi \in H_0^1(Q)$, $\psi \geq 0$ (that is possible by a density argument). Thus, for any real number k ,

$$\begin{aligned} & \int_Q I_\eta(u, k) \beta_\varepsilon \partial_t \psi dx dt - \int_Q \text{sgn}_\eta(\phi(u) - \phi(k)) \beta_\varepsilon \nabla \phi(u) \cdot \nabla \psi dx dt \\ & - \int_Q \text{sgn}_\eta(\phi(u) - \phi(k)) \psi \nabla \phi(u) \cdot \nabla \beta_\varepsilon dx dt \\ & + \int_Q b(x) \beta_\varepsilon \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}(u) - \mathbf{F}_\eta(u, k) \} \cdot \nabla \psi dx dt \\ & + \int_Q b(x) \psi \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}(u) - \mathbf{F}_\eta(u, k) \} \cdot \nabla \beta_\varepsilon dx dt \\ & - \int_Q \{ \text{sgn}_\eta(\phi(u) - \phi(k)) g(t, x, u) + \nabla b(x) \cdot \mathbf{F}_\eta(u, k) \} \psi \beta_\varepsilon dx dt \\ & + \int_{\Sigma_{hp}} (b_h \mathbf{F}_{h,\eta}(u, k) - b_p \mathbf{F}_{p,\eta}(u, k)) \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1} \geq 0. \end{aligned}$$

All the integrals involving the function β_ε itself goes to zero with ε . To take the limit with respect to ε in the second line we use Lemma 2 and for the fourth one we split the integration field into Q_p and Q_h so that on the parabolic zone, we have by introducing the trace u^ϕ ,

$$\begin{aligned} & \lim_{\varepsilon \rightarrow 0^+} \int_{Q_p} b_p(x) \psi \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}_p(u) - \mathbf{F}_{p,\eta}(u, k) \} \cdot \nabla \beta_\varepsilon dx dt \\ & = - \int_{\Sigma_{hp}} b_p \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}_p(u^\phi) - \mathbf{F}_{p,\eta}(u, k) \} \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1} \end{aligned}$$

and on the hyperbolic one, in view of (9), we ensure that

$$\begin{aligned} & \lim_{\varepsilon \rightarrow 0^+} \int_{Q_h} b_h \psi \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}_h(u) - \mathbf{F}_{h,\eta}(u, k) \} \cdot \nabla \beta_\varepsilon dx dt \\ & = \int_{\Sigma_{hp}} b_h \{ \text{sgn}_\eta(\phi(u^\tau) - \phi(k)) \mathbf{f}_h(u^\tau) - \mathbf{F}_{h,\eta}(u^\tau, k) \} \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1}. \end{aligned}$$

Eventually it follows, for any $\psi \in H_0^1(Q)$,

$$\begin{aligned} & - \int_{\Sigma_{hp}} (b_h \mathbf{f}_h(u^\tau) - b_p \mathbf{f}_p(u^\phi)) \cdot \boldsymbol{\nu}_h \text{sgn}_\eta(\phi(u) - \phi(k)) \psi dt d\mathcal{H}^{n-1}. \\ & - \int_{\Sigma_{hp}} b_p \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}_p(u^\phi) - \mathbf{F}_{p,\eta}(u, k) \} \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1} \\ & + \int_{\Sigma_{hp}} b_h \{ \text{sgn}_\eta(\phi(u^\tau) - \phi(k)) \mathbf{f}_h(u^\tau) - \mathbf{F}_{h,\eta}(u^\tau, k) \} \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1} \\ & + \int_{\Sigma_{hp}} (b_h \mathbf{F}_{h,\eta}(u, k) - b_p \mathbf{F}_{p,\eta}(u, k)) \cdot \boldsymbol{\nu}_h \psi dt d\mathcal{H}^{n-1} \geq 0. \end{aligned}$$

Consequently, for any positive η and any real number k ,

$$\begin{aligned} & - (b_h \mathbf{f}_h(u^\tau) - b_p \mathbf{f}_p(u^\phi)) \cdot \boldsymbol{\nu}_h \text{sgn}_\eta(\phi(u) - \phi(k)) \\ & - b_p \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}_p(u^\phi) - \mathbf{F}_{p,\eta}(u, k) \} \cdot \boldsymbol{\nu}_h \\ & + b_h \{ \text{sgn}_\eta(\phi(u^\tau) - \phi(k)) \mathbf{f}_h(u^\tau) - \mathbf{F}_{h,\eta}(u^\tau, k) \} \cdot \boldsymbol{\nu}_h \\ & + (b_h \mathbf{F}_{h,\eta}(u, k) - b_p \mathbf{F}_{p,\eta}(u, k)) \cdot \boldsymbol{\nu}_h \geq 0 \end{aligned}$$

a.e. on $(0, T)$, \mathcal{H}^{n-1} a.e. on Γ_{hp} . By taking the limit with respect to η in the above inequality we obtain

$$(\text{sgn}(u^\tau - k) - \text{sgn}(u^\phi - k))b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(k)) \cdot \boldsymbol{\nu}_h \geq 0,$$

that is (15) when k belongs to $I(u^\tau, u^\phi)$. \square

Now we are able to state the uniqueness property that is a time-Lipschitzian dependence in $L^1(\Omega)$ of a weak entropy solution to (1) with respect to its initial condition.

Theorem 1. *Assume that there exists a constant $C > 0$ and a real number $\theta \in [\frac{1}{2}, 1]$ such that, for all $(a, b) \in [\phi(M_2(T)), \phi(M_1(T))]^2$,*

$$|(\mathbf{f}_p \circ \phi^{-1})(a) - (\mathbf{f}_p \circ \phi^{-1})(b)|_n \leq C|a - b|^\theta. \quad (16)$$

Let u and v be two weak entropy solutions to (1) for initial data u_0 and v_0 . Then for almost all $t \in (0, T)$,

$$\int_{\Omega} |u(t, \cdot) - v(t, \cdot)| dx \leq e^{M_g t} \int_{\Omega} |u(t, \cdot) - v(t, \cdot)| dx.$$

Proof. First we introduce $(\rho_j)_{j \in \mathbb{N}^*}$ a sequence of mollifiers on \mathbb{R} and \mathcal{W}_j , the sequence of mollifiers on \mathbb{R}^{n+1} defined by

$$\forall j > 0, \forall p = (t, x) \in \mathbb{R}^{n+1}, \mathcal{W}_j(p) = \rho_j(t) \prod_{i=1}^n \rho_j(x_i).$$

In a first step, we focus on the parabolic area and we use the method of doubling the time variable only. Let γ be a nonnegative element of $\mathcal{D}(0, T)$. We consider the mapping $\alpha_j : (t, \tilde{t}) \rightarrow \gamma((t+\tilde{t})/2)\rho_j((t-\tilde{t})/2)$. Note that, for j small enough, α_j belongs to $\mathcal{D}((0, T) \times (0, T))$. Then we choose in (13) written for u in variables (t, x) , the test function $\varphi(t, x) = \text{sgn}_\eta(\phi(u(t, x)) - \phi(v(\tilde{t}, x)))\alpha_j(t, \tilde{t})$ and we integrate with respect to \tilde{t} over $[0, T]$. In (13) written for v in variables (\tilde{t}, x) the test function $\varphi(\tilde{t}, x) = -\text{sgn}_\eta(\phi(u(t, x)) - \phi(v(\tilde{t}, x)))$ and we integrate with respect to t over $[0, T]$. We add up and it comes (by sake of simplicity, we add a “tilde” superscript to any unknown in the \tilde{t} variable).

$$\begin{aligned} & \int_0^T \int_0^T \langle \partial_t u - \partial_{\tilde{t}} \tilde{v}, \text{sgn}_\eta(\phi(u) - \phi(\tilde{v})) \rangle \alpha_j dt d\tilde{t} \\ & + \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) |\nabla(\phi(u) - \phi(\tilde{v}))|_n^2 \alpha_j dx dt d\tilde{t} \\ & - \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) b_p(\mathbf{f}_p(u) - \mathbf{f}_p(\tilde{v})) \cdot \nabla(\phi(u) - \phi(\tilde{v})) \alpha_j dx dt d\tilde{t} \\ & + \int_0^T \int_{Q_p} (g_p(t, x, u) - g_p(\tilde{t}, x, \tilde{v})) \text{sgn}_\eta(\phi(u) - \phi(\tilde{v})) \alpha_j dx dt d\tilde{t} \\ = & \int_0^T \int_{\Sigma_{hp}} \text{sgn}_\eta(\phi(u) - \phi(\tilde{v})) b_h \mathbf{f}_h(u^\tau) \cdot \boldsymbol{\nu}_h \alpha_j dt d\mathcal{H}^{n-1} d\tilde{t} \\ & - \int_0^T \int_{\Sigma_{hp}} \text{sgn}_\eta(\phi(u) - \phi(\tilde{v})) b_h \mathbf{f}_h(\tilde{v}^\tau) \cdot \boldsymbol{\nu}_h \alpha_j dt d\mathcal{H}^{n-1} d\tilde{t} \end{aligned} \quad (17)$$

By using the Young's inequality (with $p = 2$) in the third line of (17) we obtain

$$\begin{aligned} & \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) |\nabla(\phi(u) - \phi(\tilde{v}))|_n^2 \alpha_j dx dt d\tilde{t} \\ & - \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) b_p(\mathbf{f}_p(u) - \mathbf{f}_p(\tilde{v})) \cdot \nabla(\phi(u) - \phi(\tilde{v})) \alpha_j dx dt d\tilde{t} \\ \geq & -\frac{1}{2} \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) b_p^2 |\mathbf{f}_p(u) - \mathbf{f}_p(\tilde{v})|_n^2 \alpha_j dx dt d\tilde{t} \\ & + \frac{1}{2} \int_0^T \int_{Q_p} \text{sgn}'_\eta(\phi(u) - \phi(\tilde{v})) |\nabla(\phi(u) - \phi(\tilde{v}))|_n^2 \alpha_j dx dt d\tilde{t} \end{aligned}$$

So, by virtue of (16), we claim the existence of a constant $C' > 0$ such that

$$\begin{aligned} & \int_0^T \int_{Q_p} sgn'_\eta(\phi(u) - \phi(\tilde{v})) |\nabla(\phi(u) - \phi(\tilde{v}))|^2 \alpha_j dx dt d\tilde{t} \\ & - \int_0^T \int_{Q_p} sgn'_\eta(\phi(u) - \phi(\tilde{v})) b_p(\mathbf{f}_p(u) - \mathbf{f}_p(\tilde{v})) \cdot \nabla(\phi(u) - \phi(\tilde{v})) \alpha_j dx dt d\tilde{t} \\ & \geq -C' \int_0^T \int_{Q_p} b_p^2 |\phi(u) - \phi(\tilde{v})|^{2\theta} sgn'_\eta(\phi(u) - \phi(\tilde{v})) \alpha_j dx dt d\tilde{t}. \end{aligned}$$

Since $\theta \geq \frac{1}{2}$, the term in the right-hand side of the above inequality tends to 0 as η goes to 0^+ . For the evolutionary term of (17) we use again the time integration by parts of F.Mignot Lemma ([5] p.31) to assert that

$$\int_0^T \langle \langle \partial_t u, sgn_\eta(\phi(u) - \phi(\tilde{v})) \rangle \rangle \alpha_j dt = - \int_{Q_p} \left(\int_{\tilde{v}}^u sgn_\eta(\phi(\tau) - \phi(\tilde{v})) d\tau \right) \partial_t \alpha_j dx dt$$

and

$$\int_0^T \langle \langle \partial_{\tilde{t}} \tilde{v}, sgn_\eta(\phi(u) - \phi(\tilde{v})) \rangle \rangle \alpha_j d\tilde{t} = - \int_{Q_p} \left(\int_{\tilde{v}}^u sgn_\eta(\phi(u) - \phi(\tau)) d\tau \right) \partial_{\tilde{t}} \alpha_j dx d\tilde{t}$$

Then we take the limit with respect to η in (17) and that gives:

$$\begin{aligned} & - \int_0^T \int_{Q_p} |u - \tilde{v}| (\partial_t \alpha_j + \partial_{\tilde{t}} \alpha_j) dx dt d\tilde{t} \\ & \leq \int_0^T \int_{Q_p} |g_p(t, x, u) - g_p(t, x, \tilde{v})| \alpha_j dx dt d\tilde{t} \\ & + \int_0^T \int_{\Sigma_{h_p}} sgn(\phi(u) - \phi(\tilde{v})) b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(\tilde{v}^\tau)) \cdot \boldsymbol{\nu}_h \alpha_j d\mathcal{H}^{n-1} dt d\tilde{t}. \end{aligned}$$

Finally when j goes to $+\infty$ we get

$$\begin{aligned} & - \int_{Q_p} |u - v| \gamma'(t) dx dt \leq M_{g_p} \int_{Q_p} |u - v| \gamma(t) dx dt \\ & \int_{\Sigma_{h_p}} sgn(u^\phi - v^\phi) b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h \gamma(t) dt d\mathcal{H}^{n-1}. \end{aligned} \tag{18}$$

Next we focus on the hyperbolic area. We use here the classical method of doubling (all) the variables due to S.N.Kruzhkov [8]. Briefly speaking, for all $(p, \tilde{p}) \in ((0, T) \times \mathbb{R}^n)^2$, we set

$$\psi_j(t, x, \tilde{t}, \tilde{x}) = \psi_j(p, \tilde{p}) = \gamma((t + \tilde{t})/2) \zeta((x + \tilde{x})/2) \mathcal{W}_j(p - \tilde{p})$$

where $\gamma \in \mathcal{D}(0, T)$ with $\gamma \geq 0$, $\zeta \in \mathcal{D}(\mathbb{R}^n)$ with $\zeta \geq 0$. The variables (\tilde{t}, \tilde{x}) being frozen, we choose in (11) written for u in variables (t, x) , $k = \tilde{v} = v(\tilde{t}, \tilde{x})$ and $\varphi(t, x) = \psi_j(p, \tilde{p})$. Now, the variable (t, x) being frozen in (11) written for \tilde{v} in variables (\tilde{t}, \tilde{x}) , we choose $k = u = u(t, x)$ and $\varphi(\tilde{t}, \tilde{x}) = \psi_j(p, \tilde{p})$. We integrate over Q_h with respect to the corresponding frozen variables and we add the two resulting

inequalities. That yields

$$\begin{aligned}
& \int_{Q_h \times Q_h} |u - \tilde{v}| (\partial_t \psi_j + \partial_{\tilde{t}} \psi_j) dp d\tilde{p} \\
& + \int_{Q_h \times Q_h} \Phi(u, \tilde{v}) \cdot (b_h \nabla_x \psi_j + \tilde{b}_h \nabla_{\tilde{x}} \psi_j) dp d\tilde{p} \\
& - \int_{Q_h \times Q_h} (G_h(u, \tilde{v}) + G_h(\tilde{v}, u)) \psi_j dp d\tilde{p} \\
\geq & \int_{Q_h} \int_{\Sigma_h \setminus \Sigma_{hp}} b_h \operatorname{sgn}(\tilde{v}) (\mathbf{f}_h(\tilde{v}) - \mathbf{f}_h(0)) \cdot \boldsymbol{\nu}_h \psi_j(\sigma, \tilde{p}) dt d\mathcal{H}_\sigma^{n-1} d\tilde{p} \\
& + \int_{Q_h} \int_{\Sigma_h \setminus \Sigma_{hp}} \tilde{b}_h \operatorname{sgn}(u) (\mathbf{f}_h(u) - \mathbf{f}_h(0)) \cdot \boldsymbol{\nu}_h \psi_j(p, \tilde{\sigma}) dt d\mathcal{H}_{\tilde{\sigma}}^{n-1} dp \\
& - \int_{Q_h} \int_{\Sigma \setminus \Sigma_{hp}} b_h \operatorname{sgn}(u^\tau) (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(0)) \cdot \boldsymbol{\nu}_h \psi_j(\sigma, \tilde{p}) dt d\mathcal{H}_\sigma^{n-1} d\tilde{p} \\
& - \int_{Q_h} \int_{\Sigma \setminus \Sigma_{hp}} \tilde{b}_h \operatorname{sgn}(\tilde{v}^\tau) (\mathbf{f}_h(\tilde{v}^\tau) - \mathbf{f}_h(0)) \cdot \boldsymbol{\nu}_h \psi_j(p, \tilde{\sigma}) dt d\mathcal{H}_{\tilde{\sigma}}^{n-1} dp \\
& + \int_{Q_h} \int_{\Sigma_{hp}} b_h \Phi_h(u^\tau, \tilde{v}) \cdot \boldsymbol{\nu}_h \psi_j(\sigma, \tilde{p}) dt d\mathcal{H}_\sigma^{n-1} d\tilde{p} \\
& + \int_{Q_h} \int_{\Sigma_{hp}} \tilde{b}_h \Phi_h(\tilde{v}^\tau, u) \cdot \boldsymbol{\nu}_h \psi_j(\tilde{\sigma}, p) dt d\mathcal{H}_{\tilde{\sigma}}^{n-1} dp
\end{aligned}$$

There is no difficulty to take the limit with respect to j in the previous inequality and we obtain

$$\begin{aligned}
- \int_{Q_h} |u - v| \gamma'(t) dx dt & \leq - \int_{Q_h} \operatorname{sgn}(u - v) (g_h(t, x, u) - g_h(t, x, v)) \gamma(t) dx dt \\
& - \int_{\Sigma_{hp}} \operatorname{sgn}(u^\tau - v^\tau) (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h b_h \gamma(t) d\mathcal{H}^{n-1} dt.
\end{aligned} \tag{19}$$

Observe that as soon as, for a.e. $\bar{\sigma}$ in Σ_{hp} , the mapping $\tau \rightarrow b_h(\bar{\sigma}) \mathbf{f}_h(\tau) \cdot \boldsymbol{\nu}_h(\bar{\sigma})$ is nondecreasing, the second term in the right hand side of (19) falls. As a consequence, it warrants the uniqueness on the hyperbolic zone in first and then on the parabolic one by coming back to (18) and using that $u^\tau = v^\tau$ a.e. on Σ_{hp} . This framework that has been investigated in earlier works [1, 7]. Here, we add inequalities (18) and (19). Consequently

$$\begin{aligned}
& - \int_Q |u - v| \gamma'(t) dx dt \leq M_g \int_Q |u - v| \gamma(t) dx dt \\
& + \int_{\Sigma_{hp}} b_h \operatorname{sgn}(u^\phi - v^\phi) (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h \gamma(t) d\mathcal{H}^{n-1} dt \\
& - \int_{\Sigma_{hp}} b_h \operatorname{sgn}(u^\tau - v^\tau) (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h \gamma(t) d\mathcal{H}^{n-1} dt.
\end{aligned} \tag{20}$$

For almost all t in $]0, T[$, \mathcal{H}^{n-1} a.e. on Γ_{hp} , we set

$$J = (\operatorname{sgn}(u^\phi - v^\phi) - \operatorname{sgn}(u^\tau - v^\tau)) b_h (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h.$$

Our aim is to prove that $J \leq 0$ on Σ_{hp} . To do so we make a pointwise reasoning and so we have to distinguish several cases.

If $\operatorname{sgn}(u^\phi - v^\phi) = \operatorname{sgn}(u^\tau - v^\tau)$ or $u^\tau = v^\tau$, then $J = 0$.

If $\operatorname{sgn}(u^\phi - v^\phi) = -\operatorname{sgn}(u^\tau - v^\tau)$ or $u^\phi = v^\phi$ and $u^\tau \neq v^\tau$, then

$$J = -2b_h \operatorname{sgn}(u^\tau - v^\tau) (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h.$$

Let us assume that $u^\tau < v^\tau$, the reasoning when $u^\tau > v^\tau$ being similar. In this framework $J = 2b_h (\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h$. Here we consider three different cases.

i) if $v^\phi \in]u^\tau, v^\tau[$, we choose $k = v^\phi$ in (15) written for u and for v and we add the two resulting inequalities. We have

$$b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \cdot \boldsymbol{\nu}_h \leq 0.$$

ii) if $v^\phi \leq u^\tau$, we have $v^\phi \leq u^\tau < v^\tau$. Then we choose $k = u^\tau$ in (15) written for v . That gives

$$b_h(\mathbf{f}_h(v^\tau) - \mathbf{f}_h(u^\tau)) \cdot \boldsymbol{\nu}_h \geq 0.$$

iii) if $v^\phi \geq v^\tau$, then $u^\tau < v^\tau < u^\phi$. We choose $k = v^\tau$ in (15) written for u and $-b_h(\mathbf{f}_h(u^\tau) - \mathbf{f}_h(v^\tau)) \geq 0$.

Consequently we deduce from (20) that

$$-\int_Q |u - v| \gamma'(t) dx dt \leq M_g \int_Q |u - v| \gamma(t) dx dt.$$

Finally we consider, for almost all t in $(0, T)$, a sequence of test functions approximating the characteristic function $\mathbb{I}_{[0, t]}$. Then we use the initial condition (4) and the Gronwall's Lemma to close the proof of Theorem 1. \square

4 The existence property

We use the vanishing viscosity method to approximate a weak entropy solution to (1). To do so we introduce a viscous problem related to (1) and prove that it has a unique weak solution that fulfills some *a priori* estimates uniform with respect to the viscous parameter. Then by applying E.Yu.Panov's works [11, 13] providing - under suitable non-degeneracy conditions for the flux \mathbf{f}_h and \mathbf{f}_p - a precompactness property in L^1 for the sequence of viscous solutions - we are able to establish that this sequence converges (in the L^1 -sense) towards a weak entropy solution to (1).

4.1 The viscous problem

Let μ be a positive real number. We set

$$\lambda_\mu(x) = \mathbb{I}_{\Omega_p}(x) + \mu \mathbb{I}_{\Omega_h}(x), \quad \phi_\mu = \phi + \mu \mathbb{I}_{\mathbb{R}},$$

and we consider of viscous problem related to (1) that means that we are interested in the existence and uniqueness of a measurable and bounded function u_μ satisfying

$$\begin{cases} \partial_t u_\mu + \operatorname{div}_x(b(x)\mathbf{f}(u_\mu)) + g(t, x, u_\mu) &= \operatorname{div}_x(\lambda_\mu(x)\nabla\phi_\mu(u_\mu)) & \text{in } Q, \\ u_\mu &= 0 & \text{on } \Gamma, \\ u_\mu(0, \cdot) &= u_0 & \text{on } \Omega. \end{cases} \quad (21)$$

In order to deal with bounded solutions, we introduce the following assumptions on \mathbf{f}_h and \mathbf{f}_p that will be discussed below, see proof of (24) in Proposition 3: we suppose that \mathcal{H}^{n-1} a.e. on Γ_{hp} , for almost all t in $(0, T)$,

$$(b_p \mathbf{f}_p(M_1(t)) - b_h \mathbf{f}_h(M_1(t))) \cdot \boldsymbol{\nu}_h \geq 0, \quad (22)$$

$$(b_p \mathbf{f}_p(M_2(t)) - b_h \mathbf{f}_h(M_2(t))) \cdot \boldsymbol{\nu}_h \leq 0. \quad (23)$$

We also introduce the functional space

$$W(0, T) = \{v \in L^2(0, T; H_0^1(\Omega)), \partial_t v \in L^2(0, T; H^{-1}(\Omega))\},$$

and denote by $\langle \cdot, \cdot \rangle$ the pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$.

This way we may state

Proposition 3. *Under (22) and (23) there exists a unique solution $u_\mu \in W(0, T) \cap L^\infty(Q)$ to (21) such that*

$$M_2(t) \leq u_\mu(t, \cdot) \leq M_1(t) \text{ for all } t \in [0, T], \text{ a.e. in } \Omega, \quad (24)$$

$$u_\mu(0, \cdot) = u_0 \text{ a.e. in } \Omega. \quad (25)$$

Moreover, for any $v \in H_0^1(\Omega)$, and for almost all $t \in (0, T)$, u_μ satisfies the variational equality

$$\langle \partial_t u_\mu, v \rangle + \int_\Omega ((\lambda_\mu(x)\nabla\phi_\mu(u_\mu) - b(x)\mathbf{f}(u_\mu)) \cdot \nabla v + g(t, x, u_\mu)v) dx = 0. \quad (26)$$

Proof. We focus on the proof of (24). In a first step we use a troncation process. For any real numbers a , b and c we set $\mathcal{B}(a, b, c) = \max\{a, \min\{b, c\}\}$. Then, for a fixed μ , we introduce the auxiliary problem

$$\begin{cases} \text{Find } u_\mu \text{ in } W(0, T) \text{ such that a.e. on } (0, T) \text{ and for all } v \in H_0^1(\Omega), \\ \langle \partial_t u_\mu, v \rangle + \int_{\Omega} ((\lambda_\mu(x) \phi'_\mu(u_\mu^*) \nabla u_\mu - b(x) \mathbf{f}(u_\mu^*)) \cdot \nabla v + g(t, x, u_\mu^*) v) dx = 0 \\ u_\mu^*(0, \cdot) = u_0 \text{ a.e. on } \Omega \end{cases} \quad (27)$$

where $u_\mu^* = \mathcal{B}(M_2(t), u_\mu, M_1(t))$.

Let us prove that (24) - (26) is equivalent to (27). It is clear that if u_μ satisfies (24) - (26) then u_μ fulfills (27). Conversely let u_μ be a solution to (27). To obtain the majorization for u_μ in (24) we may consider in (27) the test-function $v_\eta = \text{sgn}_\eta(u_\mu - M_1(t))^+$ and we integrate over $(0, s)$, for any $s \in (0, T)$. One adds and substracts $\langle \partial_t M_1(t), u_\mu \rangle$ in the evolution term. Furthermore, since v_η is supported on $\{u_\mu > M_1(t)\}$ we have (by denoting $Q_s = (0, s) \times \Omega$)

$$\begin{aligned} & \int_{Q_s} (-b(x) \mathbf{f}(u_\mu^*)) \cdot \nabla v_\eta + g(t, x, u_\mu^*) v_\eta dx dt \\ &= \int_{Q_s} (-b(x) \mathbf{f}(M_1(t))) \cdot \nabla v_\eta + g(t, x, M_1(t)) v_\eta dx dt \end{aligned}$$

For the convection term, we use a Green's formula to obtain

$$\begin{aligned} - \int_{Q_s} b(x) \mathbf{f}(u_\mu^*) \cdot \nabla v_\eta dx dt &= \sum_{i \in \{h, p\}} \int_{Q_{i, s}} \mathbf{f}_i(M_1(t)) \cdot \nabla b_i(x) v_\eta dx dt \\ &+ \int_{\Sigma_{hp}} (b_p \mathbf{f}_p(M_1(t)) - b_h \mathbf{f}_h(M_1(t))) \cdot \nu_h v_\eta dt d\mathcal{H}^{n-1} \end{aligned}$$

Then, in view of (22), we ensure that the interface integral is nonnegative.

Owing to the definition of v_η the diffusion term is also nonnegative. Then, when η goes to 0^+ thanks to the Lebesgue dominated convergence Theorem it yields,

$$\begin{aligned} & \int_{\Omega} (u_\mu(s, x) - M_1(s))^+ dx + \int_{Q_s} M_1'(t) \text{sgn}(u_\mu - M_1(t))^+ dx dt \\ &+ \sum_{i \in \{h, p\}} \int_{Q_{i, s}} (\mathbf{f}_i(M_1(t)) \cdot \nabla b_i + g_i(t, x, M_1(t))) \text{sgn}(u_\mu - M_1(t))^+ dx dt \leq 0. \end{aligned}$$

Due to the definition of M_1 , everywhere on $Q_{i, s}$,

$$M_1'(t) + (\mathbf{f}_i(M_1(t)) \cdot \nabla b_i + g_i(t, x, M_1(t))) \geq 0,$$

and the conclusion follows.

In a similar way, to prove the minorization in (24) we may consider the test function $v_\eta = -\text{sgn}_\eta(u_\mu - M_2(t))^-$ in (27) and we use (23) to state that the integral over Σ_{hp} that appears when we deal with the convection term is nonnegative.

Thus the existence property for (21) is reduced to an existence result to (27). To do so we use the Schauder-Tychonoff fixed point Theorem as in [7] while the uniqueness of a solution to (24)-(26) is obtained by a Holmgren-type duality method (see [7]). □

Let us now collect an *a priori* estimate for the sequence $(u_\mu)_{\mu > 0}$ proper to study its limit when μ goes to 0^+ .

Proposition 4. *There exists a positive constant C independent of μ such that*

$$\|(\lambda_\mu)^{1/2} \nabla \widehat{\phi}(u_\mu)\|_{L^2(Q)^n}^2 + \|(\mu \lambda_\mu)^{1/2} \nabla u_\mu\|_{L^2(Q)^n}^2 \leq C, \quad (28)$$

where $\widehat{\phi}(u_\mu) = \int_0^{u_\mu} \sqrt{\phi'(\tau)} d\tau$.

Proof. We choose $v = u_\mu$ in (26) and integrate over $]0, T[$. We have:

$$\int_0^T \langle \partial_t u, u \rangle dt = \frac{1}{2} \|u_\mu(T, \cdot)\|_{L^2(\Omega)}^2 - \frac{1}{2} \|u_0\|_{L^2(\Omega)}^2 \leq \frac{1}{2} \|u_\mu(T, \cdot)\|_{L^2(\Omega)}^2.$$

Moreover,

$$\begin{aligned} \int_Q b(x) \mathbf{f}(u_\mu) \cdot \nabla u_\mu dx dt &= \int_Q b(x) \operatorname{div} \left(\int_0^{u_\mu} \mathbf{f}(\tau) d\tau \right) dx dt \\ &= \sum_{i \in \{h, p\}} \int_{Q_i} b_i(x) \operatorname{div} \mathbf{F}_i(u_\mu) dx dt. \end{aligned}$$

where $\mathbf{F}_i(u_\mu) = \int_0^{u_\mu} \mathbf{f}_i(\tau) d\tau$.

So by a Green's formula on each Q_i , $i = h, p$, the convection term can be written as

$$\sum_{i \in \{h, p\}} \int_{Q_i} \nabla b(x) \mathbf{F}_i(u_\mu) dx dt + \int_{\Sigma_{hp}} (b_p(\bar{\sigma}) \mathbf{F}_p(u_\mu) - b_h(\bar{\sigma}) \mathbf{F}_h(u_\mu)) \cdot \boldsymbol{\nu}_h dt d\mathcal{H}^{n-1}.$$

Thanks to (24), we assert that the convection term is bounded independently of μ . The reaction term is also clearly bounded (as a consequence of (24) and for the diffusion term we write:

$$\int_Q \lambda_\mu \nabla \phi_\mu(u_\mu) \cdot \nabla u_\mu dx dt = \int_Q \lambda_\mu \phi'(u_\mu) |\nabla u_\mu|_n^2 dx dt + \mu \int_Q \lambda_\mu |\nabla u_\mu|_n^2 dx dt$$

where,

$$\int_Q \lambda_\mu \phi'(u_\mu) |\nabla u_\mu|_n^2 dx dt = \int_Q (\sqrt{\lambda_\mu} |\nabla \widehat{\phi}(u_\mu)|_n)^2 dx dt.$$

This way,

$$\int_Q \lambda_\mu \nabla \phi_\mu(u_\mu) \cdot \nabla u_\mu dx dt = \|(\lambda_\mu)^{1/2} \nabla \widehat{\phi}(u_\mu)\|_{L^2(Q)^n}^2 + \|(\mu \lambda_\mu)^{1/2} \nabla u_\mu\|_{L^2(Q)^n}^2$$

The conclusion follows. \square

4.2 The viscous limit

Since the estimates (24) and (28) are not sufficient not allow us to pass to the limit with μ on the parabolic zone (mainly it misses an estimate on the time derivative of $u_{\mu|_{Q_p}}$ in $L^2(0, T; V')$), we use E.Yu.Panov's results in [13]. The author introduces a so-called nonlinear condition for the flux \mathbf{f}_p so that the sequence $(u_{\mu|_{Q_p}})_{\mu>0}$ is precompact in $L^1(Q_p)$. Indeed assume that:

Assumption 1. For almost all $x \in \Omega_p$, for all $\xi \in \mathbb{R}^n$ with $\xi \neq 0$, the functions $\lambda \mapsto b_p(x) \mathbf{f}_p(\lambda) \cdot \xi$ and $\lambda \mapsto \phi(\lambda) \xi^2$ are not linear simultaneously on any non-degenerate intervals.

Then, as soon as (24) and (28) hold, there exists a subsequence, still denoted $(u_{\mu|_{Q_p}})_{\mu>0}$, that converges strongly in $L^1(Q_p)$. This way, we may state:

Theorem 2. The sequence $(u_\mu)_{\mu>0}$ of solutions to (21), admits a subsequence that converges strongly in $L^1(Q)$ towards a function $u \in L^\infty(Q)$.

Moreover u is the weak entropy solution of the problem (1).

Remark 3. The strong convergence property on Q_p could also be obtained if we replace Assumption 1 by the following one

$$\phi \text{ is Hölder continuous with an exponent } \tau \in (0, 1),$$

as it is supposed in [7].

Proof of theorem 2. Thanks to Assumption 1 we make sure that we can extract a subsequence of $(u_\mu|_{Q_p})_{\mu>0}$ that strongly converges in $L^1(Q_p)$. Besides, from [13] and by virtue of (8) we know that we can extract a subsequence of $(u_\mu|_{Q_h})_{\mu>0}$ that strongly converges in $L^1(Q_h)$. Thus there exists a subsequence of $(u_\mu)_{\mu>0}$ that converges strongly in $L^1(Q)$ towards a function u of $L^\infty(Q)$. It remains to show that u is a weak entropy solution to (1). To this purpose we choose in (26) the test function $v_\mu^\eta = \text{sgn}_\eta(\phi(u_\mu) - \phi(k))\varphi$, where $k \in \mathbb{R}$, $\varphi \in \mathcal{D}([0, T] \times \Omega)$, $\varphi \geq 0$. We integrate over $[0, T]$ to have

$$\int_0^T \langle \partial_t u_\mu, v_\mu^\eta \rangle dt + \int_Q ((\lambda_\mu \nabla \phi_\mu(u_\mu) - b(x) \mathbf{f}(u_\mu)) \cdot \nabla v_\mu^\eta + g(t, x, u_\mu) v_\mu^\eta) dx dt = 0. \quad (29)$$

An integration-by-parts in the evolution term gives

$$\int_0^T \langle \partial_t u_\mu, v_\mu^\eta \rangle dt = - \int_Q I_\eta(u_\mu, k) \partial_t \varphi dx dt - \int_\Omega I_\eta(u_0, k) \varphi(0, \cdot) dx.$$

Due to the definition of sgn_η and ϕ_μ , we obtain for the diffusion term

$$\begin{aligned} \int_Q \lambda_\mu \nabla \phi_\mu(u_\mu) \cdot \nabla v_\mu^\eta dx dt &\geq \int_Q \lambda_\mu \text{sgn}_\eta(\phi(u_\mu) - \phi(k)) \nabla \phi(u_\mu) \cdot \nabla \varphi dx dt \\ &\quad + \mu \int_Q \lambda_\mu \text{sgn}_\eta(\phi(u_\mu) - \phi(k)) \nabla u_\mu \cdot \nabla \varphi dx dt. \end{aligned}$$

Note that the second term of the right-hand side goes to zero with μ thanks to estimate (28). The convection term is written as

$$\begin{aligned} & - \sum_{i \in \{h, p\}} \int_Q b_i(x) \mathbf{f}_i(u_\mu) \cdot \nabla \phi(u_\mu) \text{sgn}'_\eta(\phi(u_\mu) - \phi(k)) \varphi dx dt \\ & - \sum_{i \in \{h, p\}} \int_Q b_i(x) \text{sgn}_\eta(\phi(u_\mu) - \phi(k)) \mathbf{f}_i(u_\mu) \cdot \nabla \varphi dx dt. \end{aligned}$$

Since the μ and η -limits in second line does not bring difficulties we focus on the first line for $i = h$, the reasoning for $i = p$ being similar. We denote

$$J_{\mu, \eta} = - \int_{Q_h} b_h(x) \mathbf{f}_h(u_\mu) \cdot \nabla \phi(u_\mu) \text{sgn}'_\eta(\phi(u_\mu) - \phi(k)) \varphi dx dt.$$

Thus, owing to definition of $\mathbf{F}_{h, \eta}$,

$$J_{\mu, \eta} = - \int_{Q_h} b(x) \text{div} \mathbf{F}_{h, \eta}(u_\mu, k) \varphi dx dt.$$

So, by a Green's formula, we have

$$\begin{aligned} J_{\mu, \eta} &= \int_{Q_h} \mathbf{F}_{h, \eta}(u_\mu, k) \cdot (\nabla b_h \varphi_2 + \nabla \varphi b_h) dx dt \\ &\quad - \int_{\Sigma_{hp}} b_h \mathbf{F}_{h, \eta}(u_\mu, k) \cdot \boldsymbol{\nu}_h \varphi d\mathcal{H}^{n-1} dt. \end{aligned}$$

Now we take the limit with respect to μ . For the interface integral we assert that the sequence $(\mathbf{F}_{h, \eta}(u_\mu, k) \varphi)_{\mu>0}$ weakly converges towards $\mathbf{F}_{h, \eta}(u, k) \varphi$ in $L^2(\Sigma_{hp})^n$. Indeed, we notice first that since $\phi(u_\mu) \in L^2(0, T; H^1(\Omega))$, for almost all $t \in (0, T)$, \mathcal{H}^{n-1} a.e., $(\phi(u_\mu)|_{\Omega_h})|_{\Gamma_{hp}} = (\phi(u_\mu)|_{\Omega_p})|_{\Gamma_{hp}}$.

Moreover, $\mathbf{F}_{h, \eta}(\cdot, k)$ being a Lipschitz function, for $1 \leq q < \infty$,

$$(\mathbf{F}_{h, \eta}(u_\mu, k))_{\mu>0} \text{ strongly converges towards } \mathbf{F}_{h, \eta}(u, k) \text{ in } L^q(Q_p)^n.$$

Besides, by virtue of (28), the sequence

$$(\mathbf{F}_{h, \eta}(u_\mu, k))_{\mu>0} \text{ is uniformly bounded in } L^2(0, T; V)^n \cap L^\infty(Q)^n.$$

So $(\mathbf{F}_{h, \eta}(u_\mu, k) \varphi)_{\mu>0}$ weakly converges, up to a subsequence, towards

$\mathbf{F}_{h,\eta}(u, k)\varphi$ in $L^2(0, T; V)^n$.

Therefore, as the trace operator from $L^2(0, T; V)$ into $L^2(\Sigma_{hp})$ is linear and continuous, $(\mathbf{F}_{h,\eta}(u_\mu, k)\varphi)_{\mu>0}$ weakly converges towards

$\mathbf{F}_{h,\eta}(u, k)\varphi$ in $L^2(\Sigma_p)^n$ and then in $L^2(\Sigma_{hp})^n$.

Consequently, $\lim_{\mu \rightarrow 0^+} J_{\mu,\eta} = J_\eta$ where

$$J_\eta = \int_{Q_h} \mathbf{F}_{h,\eta}(u, k) \cdot (\nabla b_h \varphi + \nabla \varphi b_h) dx dt - \int_{\Sigma_{hp}} b_h \mathbf{F}_{h,\eta}(u, k) \cdot \boldsymbol{\nu}_h \varphi d\mathcal{H}^{n-1} dt.$$

Then, we can pass to the limit with respect to μ in each term of (26) to have

$$\begin{aligned} & \int_Q I_\eta(u_\mu, k) \partial_t \varphi dx dt + \int_\Omega I_\eta(u_0, k) \varphi(0, \cdot) dx \\ & - \int_Q \text{sgn}_\eta(\phi(u) - \phi(k)) \nabla \phi(u) \cdot \nabla \varphi dx dt \\ & + \int_Q b(x) \{ \text{sgn}_\eta(\phi(u) - \phi(k)) \mathbf{f}(u) - \mathbf{F}_\eta(u, k) \} \cdot \nabla \varphi dx dt \\ & - \int_Q \{ \text{sgn}_\eta(\phi(u) - \phi(k)) g(t, x, u) + \nabla b(x) \cdot \mathbf{F}_\eta(u, k) \} \varphi dx dt \\ & + \int_{\Sigma_{hp}} (b_h \mathbf{F}_{h,\eta}(u, k) - b_p \mathbf{F}_{p,\eta}(u, k)) \varphi \cdot \boldsymbol{\nu}_h dt d\mathcal{H}^{n-1} \geq 0, \end{aligned} \quad (30)$$

and (3) follows.

Now it remains to prove that u fulfills (4)-(5). We consider in (30) a test function φ in $\mathcal{D}([0, T] \times \Omega_h)$ and take the limit with respect to η . We obtain

$$\begin{aligned} & - \int_{Q_h} (|u - k| \partial_t \varphi + b_h(x) \Phi(u, k) \cdot \nabla \varphi) dx dt \\ & + \int_{Q_h} \text{sgn}(u - k) (g_h(t, x, u) + \nabla b_h(x) \cdot \mathbf{f}_h(k)) \varphi dx dt \\ & \leq \int_{\Omega_h} |u_0 - k| \varphi(0, \cdot) dx. \end{aligned}$$

Thus, we refer to F.Otto's work in [10] (see also [9, Chap. 2]) to ensure that

$$\text{ess lim}_{t \rightarrow 0^+} \int_{\Omega_h} |u(t, x) - u_0(x)| dx = 0.$$

In order to show that u fulfills the initial condition on the parabolic zone, we choose a test function $\varphi = \varphi_1 \varphi_2$ where φ_1 belongs to $\mathcal{D}([0, T])$ and φ_2 to $\mathcal{D}(\Omega_p)$, $\varphi_1, \varphi_2 \geq 0$. We pass to the limit with respect to η and we can state that

$$- \int_0^T \left(\int_{\Omega_p} |u - k| \varphi_2 dx + h(t) \right) \varphi_1'(t) \leq \int_{\Omega_p} |u_0 - k| \varphi_2 \varphi_1(0) dx.$$

where

$$\begin{aligned} h(t) &= \int_{\Omega_p} \int_0^t b_p(x) \Phi_p(u(\tau, x), k) \cdot \nabla \varphi_2 d\tau dx \\ &+ \int_{\Omega_p} \int_0^t \text{sgn}(u(\tau, x) - k) g_p(\tau, x, u(\tau, x)) \varphi_2 - |\phi(u(\tau, x)) - \phi(k)| \Delta \varphi_2 d\tau dx. \end{aligned}$$

So the time-dependent function

$$t \mapsto \int_{\Omega_p} |u - k| \varphi_2 dx + h(t)$$

is identified with a nonincreasing and bounded function and consequently has an essential limit when t tends to 0^+ . Since h goes to zero with t it comes, for any $\varphi_2 \in \mathcal{C}_c^\infty(\Omega_p)$ with $\varphi_2 \geq 0$,

$$\operatorname{ess\,lim}_{t \rightarrow 0^+} \int_{\Omega_p} |u(t, x) - k| \varphi_2 dx \leq \int_{\Omega_p} |u_0 - k| \varphi_2 dx.$$

The above inequality implies that u satisfies (4) (see [9] for more details).

To prove (5), we consider the family of boundary entropy - entropy flux pair (see [9, 10]) defined by, for any $\delta > 0$,

$$H_\delta(\tau, k) = ((\operatorname{dist}(\tau, I[0, k]))^2 + \delta^2)^{1/2} - \delta$$

and

$$\mathbf{Q}_{h,\delta}(\tau, k) = \int_k^\tau \partial_1 H_\delta(\lambda, k) \mathbf{f}'_h(\lambda) d\lambda.$$

Then we come back to the viscous problem (21) and choose in (26) the test function $v = \partial_1 H_\delta(u_\mu, k)\varphi$ where φ belongs to $\mathcal{D}((0, T) \times \overline{\Omega}_h)$, $\varphi \geq 0$ and $\varphi_2 = 0$ on Γ_{hp} . Let us note that $\partial_1 H_\delta(u_\mu, k)\varphi$ is an element of $L^2(0, T; H_0^1(\Omega_h))$ so that Green's formula does not give rise to integrals over Σ_{hp} . We integrate over $(0, T)$ and, noticing that $\tau \mapsto H_\delta(\tau, \cdot)$ is a convex function, it provides

$$\begin{aligned} & - \int_{Q_h} (H_\delta(u_\mu, k) \partial_t \varphi + b_h \mathbf{Q}_{h,\delta}(u_\mu, k) \cdot \nabla \varphi - \mathbf{G}_{h,\delta}(u_\mu, k) \varphi) dx dt \\ & \leq -\mu \int_{Q_h} \partial_1 H_\delta(u_\mu, k) \nabla \varphi \cdot \nabla \phi(u_\mu) dx dt \end{aligned}$$

where

$$\mathbf{G}_{h,\delta}(u_\mu, k) = \int_k^{u_\mu} \partial_{11}^2 H_\delta(\tau, k) \mathbf{f}_h(\tau) d\tau \cdot \nabla b_h + g_h(t, x, u_\mu) \partial_1 H_\delta(u_\mu, k).$$

By virtue of Theorem 2 and (28) to deal with the right hand side, there is no difficulties to take the limit with respect to μ . That gives

$$- \int_{Q_h} (H_\delta(u, k) \partial_t \varphi + b_h \mathbf{Q}_{h,\delta}(u, k) \nabla \varphi - \mathbf{G}_{h,\delta}(u, k) \varphi) dx dt \leq 0.$$

From [10] it follows that, for any ζ in $L^1(\Sigma_h \setminus \Sigma_{hp})$ with $\zeta \geq 0$,

$$\operatorname{ess\,lim}_{s \rightarrow 0^-} \int_{\Sigma_h \setminus \Sigma_{hp}} b_h \mathbf{G}_{h,\delta}(u(\sigma + s\nu_h), k) \cdot \nu_h \zeta dt d\mathcal{H}^{n-1} \geq 0,$$

that is

$$\int_{\Sigma_h \setminus \Sigma_{hp}} b_h \mathbf{G}_{h,\delta}(u^\tau, k) \cdot \nu_h \zeta dt d\mathcal{H}^{n-1} \geq 0,$$

in view of (9).

That yields first to boundary condition (5) by observing that $(\mathbf{Q}_{h,\delta})_\delta$ uniformly converges towards \mathcal{F}_h as δ goes to 0^+ et so to (10). \square
