# An elementary proof of an inequality of Maz'ya involving $L^1$ vector fields

Pierre Bousquet\*, Petru Mironeacu†

October 16 2009

## Abstract

We give a short elementary proof of the inequality

$$\|D(-\Delta)^{-1}\mathbf{f}\|_{L^q(|x|^{n(q-1)-q}dx)} \leq c(\|\mathbf{f}\|_{L^1} + \|\nabla(-\Delta)^{-1} \operatorname{div} \mathbf{f}\|_{L^1}), \mathbf{f} \in L^1(\mathbb{R}^n, \mathbb{R}^n), 1 \leq q < \frac{n}{n-1},$$

essentially established by Maz'ya [4].

## 1 Introduction

For any  $\mathbf{f} \in L^1(\mathbb{R}^n, \mathbb{R}^n)$ , we denote by  $\mathbf{u} := (-\Delta)^{-1}\mathbf{f}$  the Newtonian (logarithmic for  $n = 2$ ) potential of  $\mathbf{f}$ :

$$\mathbf{u}(x) = \int_{\mathbb{R}^n} \Gamma(x-y)\mathbf{f}(y) dy,$$

where  $\Gamma$  is the fundamental solution of  $-\Delta$ :

$$\Gamma(x) := \begin{cases} \frac{-1}{2\pi} \ln|x| & \text{if } n = 2 \\ \frac{1}{|S^{n-1}|(n-2)} \frac{1}{|x|^{n-2}} & \text{if } n \geq 3. \end{cases}$$

One of the main results in [3] states that

$$\|Du\|_{L^{n'}(\mathbb{R}^n)} \leq C(\|\mathbf{f}\|_{L^1} + \|\operatorname{div} \mathbf{f}\|_{W^{-2,n'}}) \quad (1)$$

where  $n' = n/(n-1)$ .

In [4], Maz'ya established the following family of estimates related to (1)

---

**Theorem 0** Let  $1 \leq q < n'$  and  $\mathbf{f} \in L^1(\mathbb{R}^n, \mathbb{R}^n)$ . Assume that  $\int_{\mathbb{R}^n} \mathbf{f} = \mathbf{0}$ . Let  $h := \operatorname{div} \mathbf{f}$ .

i)] If  $q > 1$  and  $\nabla(-\Delta)^{-1}h \in L^1$ , then

$$\|D\mathbf{u}\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c (\|\mathbf{f}\|_{L^1} + \|\nabla(-\Delta)^{-1}h\|_{L^1}).$$

ii)] If  $q = 1$  and  $(-\Delta)^{-1/2}h \in \mathcal{H}^1$  (where  $\mathcal{H}^1$  denotes the Hardy space), then

$$\|D\mathbf{u}\|_{L^1(|x|^{-1} dx)} \leq c (\|\mathbf{f}\|_{L^1} + \|(-\Delta)^{-1/2}h\|_{\mathcal{H}^1}).$$

These estimates partly solve Open Problem 1 in [3].

The aim of this note is to unify the two statements of Theorem 0 and to present a proof both shorter and more elementary than the original one in [4]. Our result is

**Theorem 1** Let  $1 \leq q < n'$  and  $\mathbf{f} \in L^1(\mathbb{R}^n, \mathbb{R}^n)$ . Let  $h := \operatorname{div} \mathbf{f}$ . If  $\nabla(-\Delta)^{-1}h \in L^1$ , then

$$\|D\mathbf{u}\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c (\|\mathbf{f}\|_{L^1} + \|\nabla(-\Delta)^{-1}h\|_{L^1}).$$

**Remarks.** i) In Theorem 0, it is required that  $\int_{\mathbb{R}^n} \mathbf{f} = \mathbf{0}$ . In fact, this equality is implied by the assumptions  $\mathbf{f} \in L^1$  and  $\nabla(-\Delta)^{-1}h \in L^1$ .  
ii) If  $(-\Delta)^{-1/2}h \in H$ , then  $\nabla(-\Delta)^{-1}h \in L^1$ , but the converse is false. Thus, when  $q = 1$ , Theorem 1 requires a weaker assumption than Theorem 0.

We start by proving i). The Fourier transform of  $\partial_j(-\Delta)^{-1}h$  is

$$F_j(\xi) = - \sum_k \frac{\xi_j \xi_k}{|\xi|^2} \widehat{f}_k(\xi) = - \sum_k \frac{\xi_j \xi_k}{|\xi|^2} \widehat{f}_k(0) + o(1) \text{ as } \xi \rightarrow 0.$$

The continuity of  $F_j$  at the origin implies  $\widehat{f}_j(0) = 0$ , i. e.,  $\int f_j = 0$ .

We next briefly justify ii). If  $g := (-\Delta)^{-1/2}h \in \mathcal{H}^1$ , then the Riesz transforms of  $g$  satisfy  $R_j g \in L^1$ ,  $1 \leq j \leq n$ , so that  $\nabla(-\Delta)^{-1}h = \iota(R_1 g, \dots, R_n g) \in L^1$ . In order to see that the converse is false, pick a temperate distribution  $g$  such that  $R_j g \in L^1$ ,  $1 \leq j \leq n$ , but  $g \notin L^1$ . Such a  $g$  exists, see [5], 6.16, p. 184 and the references therein. If  $\mathbf{f} := -\iota(R_1 g, \dots, R_n g) \in L^1$ , then  $(-\Delta)^{-1/2} \operatorname{div} \mathbf{f} = g \notin L^1$ , while  $\nabla(-\Delta)^{-1} \operatorname{div} \mathbf{f} = -\mathbf{f} \in L^1$ .

## 2 Proof of Theorem 1

Let  $\rho_0 \in C_c^\infty(\mathbb{R}^+)$  be such that  $0 \leq \rho_0 \leq 1$  and

$$\rho_0(r) = \begin{cases} 1 & \text{if } r \leq 1/4 \\ 0 & \text{if } r \geq 1/2 \end{cases}.$$

We introduce  $\rho(y, x) = \rho_0(|y|/|x|)$  for  $(y, x) \in \mathbb{R}^n \times \mathbb{R}^n \setminus \{0\}$ . For  $1 \leq k \leq n$ , we have

$$\partial_{x_k} \mathbf{u}(x) = c_n \int_{\mathbb{R}^n} \frac{x_k - y_k}{|x - y|^n} \mathbf{f}(y) dy = I_1(x) + I_2(x),$$

where

$$I_1(x) = c_n \int_{\mathbb{R}^n} \rho(y, x) \frac{x_k - y_k}{|x - y|^n} \mathbf{f}(y) dy, \quad I_2(x) = c_n \int_{\mathbb{R}^n} (1 - \rho(y, x)) \frac{x_k - y_k}{|x - y|^n} \mathbf{f}(y) dy.$$

We estimate  $\|I_2\|_{L^q(|x|^{n(q-1)-q} dx)}$  using the following straightforward consequence of Hölder's inequality

$$\left\| x \mapsto \int f(y) g(x, y) dy \right\|_{L^q} \leq \|f\|_{L^1} \sup_y \|g(\cdot, y)\|_{L^q(dx)}. \quad (2)$$

We have

$$|I_2(x)| \leq c \int_{|y| \geq |x|/4} |\mathbf{f}(y)| \frac{dy}{|x - y|^{n-1}}$$

so that, by (2),

$$\|I_2\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c \int |\mathbf{f}(y)| dy \sup_{y \neq 0} \left\{ \int_{|x| \leq 4|y|} \frac{|x|^{n(q-1)-q}}{|x - y|^{(n-1)q}} \right\}^{1/q}.$$

The quantity  $\int_{|x| \leq 4|y|} \frac{|x|^{n(q-1)-q}}{|x - y|^{(n-1)q}} dx$  is finite and does not depend on  $y \neq 0$  (since it depends only on the norm of  $y$  and is homogeneous of degree 0). This implies that

$$\|I_2\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c \int |\mathbf{f}(y)| dy.$$

In order to estimate  $\|I_1\|_{L^q(|x|^{n(q-1)-q} dx)}$ , we note that for  $|y| \leq |x|/2$  we have

$$\left| \frac{x_k - y_k}{|x - y|^n} - \frac{x_k}{|x|^n} \right| \leq c \frac{|y|}{|x|^n}.$$

Thus

$$|I_1(x)| \leq c \left\{ \frac{1}{|x|^n} \int_{|y| \leq |x|/2} |\mathbf{f}(y)| |y| dy + J(x) \right\}$$

where

$$J(x) := \frac{1}{|x|^{n-1}} \left| \int_{\mathbb{R}^n} \rho(y, x) \mathbf{f}(y) dy \right|.$$

Using (2), we obtain

$$\|I_1\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c \int |\mathbf{f}(y)| |y| dy \sup_{y \neq 0} \left\{ \int_{|x| \geq 2|y|} \frac{dx}{|x|^{n+q}} \right\}^{1/q}$$

$$+ c \|J\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c \|\mathbf{f}\|_{L^1} + c \|J\|_{L^q(|x|^{n(q-1)-q} dx)}.$$

It then remains to estimate  $\|J\|_{L^q(|x|^{n(q-1)-q}dx)}$ .

To start with, we assume, in addition to the hypotheses of Theorem 1, that  $\mathbf{f} \in C^\infty$ . Then we have

$$\begin{aligned} 0 &= \int_{\mathbb{R}^n} \operatorname{div} (y_1 \rho(y, x) \mathbf{f}(y)) dy \\ &= \int_{\mathbb{R}^n} \left[ \rho(y, x) f_1(y) + \frac{y_1}{|y||x|} \rho'_0 \left( \frac{|y|}{|x|} \right) \sum_i y_i f_i(y) + y_1 \rho(y, x) \operatorname{div} \mathbf{f}(y) \right] dy. \end{aligned}$$

Thus

$$\begin{aligned} \left| \int_{\mathbb{R}^n} \rho(y, x) f_1(y) dy \right| &\leq c \int_{|y| \leq |x|/2} \frac{|y|}{|x|} |\mathbf{f}(y)| dy \\ &\quad + \left| \int_{\mathbb{R}^n} y_1 \rho(y, x) \operatorname{div} \mathbf{f}(y) dy \right|. \end{aligned} \quad (3)$$

We claim that, with  $h = \operatorname{div} \mathbf{f}$ , we have

$$\left| \int_{\mathbb{R}^n} y_1 \rho(y, x) \operatorname{div} \mathbf{f}(y) dy \right| \leq c \int_{|y| \leq |x|/2} \frac{|y|}{|x|} |\nabla(-\Delta)^{-1} h(y)| dy. \quad (4)$$

Indeed, let  $\mathbf{k} := \nabla(y_1 \rho(y, x))$  and

$$\mathbf{l} := \left( -\frac{\partial}{\partial y_2}(y_2 \rho(y, x)), \frac{\partial}{\partial y_1}(y_2 \rho(y, x)), 0, \dots, 0 \right).$$

Then  $\operatorname{div} \mathbf{k} = \Delta(y_1 \rho(y, x))$ ,  $\operatorname{div} \mathbf{l} = 0$  and

$$(\mathbf{k} + \mathbf{l})_i = \begin{cases} y_1 \frac{\partial}{\partial y_1} \rho(y, x) - y_2 \frac{\partial}{\partial y_2} \rho(y, x) & \text{if } i = 1, \\ y_1 \frac{\partial}{\partial y_2} \rho(y, x) + y_2 \frac{\partial}{\partial y_1} \rho(y, x) & \text{if } i = 2, \\ y_1 \frac{\partial}{\partial y_i} \rho(y, x) & \text{if } i \geq 3. \end{cases}$$

Thus  $|\mathbf{k} + \mathbf{l}| \leq c \frac{|y|}{|x|} \mathbf{1}_{|y| \leq |x|/2}$ .

Therefore,

$$\begin{aligned} \int_{\mathbb{R}^n} y_1 \rho(y, x) \operatorname{div} \mathbf{f}(y) dy &= - \int_{\mathbb{R}^n} \operatorname{div} (\mathbf{k} + \mathbf{l})(-\Delta)^{-1}(\operatorname{div} \mathbf{f}) \\ &= \int_{\mathbb{R}^n} (\mathbf{k} + \mathbf{l}) \nabla(-\Delta)^{-1}(\operatorname{div} \mathbf{f}). \end{aligned}$$

By taking the absolute values in the above identity, we find that (4) holds under the additional assumption that  $\mathbf{f}$  is smooth. The general case follows by noting that  $(-\Delta)^{-1} \operatorname{div}$  and  $\nabla(-\Delta)^{-1} \operatorname{div}$  commute with convolution of vector fields with a scalar mollifier. Applying (4) to  $\mathbf{f} * \rho_\varepsilon$ , where  $\rho$  is a compactly supported mollifier, and letting  $\varepsilon \rightarrow 0$ , we find that (4) holds for all  $\mathbf{f}$ .

Now, (3) and (4) imply that

$$\left| \int_{\mathbb{R}^n} \rho(y, x) f_1(y) dy \right| \leq c \int_{|y| \leq |x|/2} \frac{|y|}{|x|} (|\mathbf{f}(y)| + |\nabla(-\Delta)^{-1} h(y)|) dy.$$

The same is true with  $\mathbf{f}$  instead of  $f_1$  on the left hand side. Using again (2), it follows that

$$\|J\|_{L^q(|x|^{n(q-1)-q} dx)} \leq c \{ \|\mathbf{f}\|_{L^1} + \|\nabla(-\Delta)^{-1} h\|_{L^1} \}. \quad (5)$$

This completes the proof of Theorem 1. □
