HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

DENDROIDAL SETS AS MODELS FOR HOMOTOPY OPERADS

DENIS-CHARLES CISINSKI AND IEKE MOERDIJK

ABSTRACT. The homotopy theory of ∞ -operads is defined by extending Joyal's homotopy theory of ∞ -categories to the category of dendroidal sets. We prove that the category of dendroidal sets is endowed with a model category structure whose fibrant objects are the ∞ -operads (i.e. dendroidal inner Kan complexes). This extends the theory of ∞ -categories in the sense that the Joyal model category structure on simplicial sets whose fibrant objects are the ∞ -categories is recovered from the model category structure on dendroidal sets by simply slicing over the point.

INTRODUCTION

The notion of dendroidal set is an extension of that of simplicial set, suitable for defining and studying nerves of (coloured) operads in the same way as nerves of categories feature in the theory of simplicial sets. It was introduced by one of the authors and I. Weiss in [MW07]. As explained in that paper, the category $dSet$ of dendroidal sets carries a symmetric monoidal structure, which is closely related to the Boardman-Vogt tensor product for operads [BV73]. There is also a corresponding internal Hom of dendroidal sets. The category of dendroidal sets extends the category $sSet$ of simplicial sets, in the precise sense that there are adjoint functors (left adjoint on the left)

$$i_! : sSet \rightleftarrows dSet : i^*$$

2000 *Mathematics Subject Classification.* 55P48, 55U10, 55U40, 18D10, 18D50, 18G30.

Key words and phrases. Inner Kan complex, operad, ∞ -operad, dendroidal set, ∞ -category, quasi-category, simplicial set.

with good properties. In particular, the functor $i_!$ is strong monoidal and fully faithful, and identifies \mathcal{sSet} with the slice category $dSet/\eta$, where η is the unit of the monoidal structure on $dSet$. (In fact, this adjunction is an open embedding of toposes.)

Using these adjoint functors $i_!$ and i^* , we can say more precisely how various constructions and results from the theory of simplicial sets extend to that of dendroidal sets. For example, the nerve functor $N : Cat \rightarrow \mathcal{sSet}$ and its left adjoint, which we denote by τ , naturally extend to a pair of adjoint functors

$$\tau_d : dSet \rightleftarrows Operad : N_d$$

which plays a central role in our work.

The goal of this paper is to lay the foundations for a homotopy theory of dendroidal sets and “ ∞ -operads” (or “operads-up-to-homotopy”, or “quasi-operads”) which extends the simplicial theory of ∞ -categories (or quasi-categories) which has recently been developed by Joyal, Lurie and others. Our main result is the existence of a Quillen closed model structure on the category of dendroidal sets, having the following properties:

1. This Quillen model structure on $dSet$ is symmetric monoidal (in the sense of [Hov99]) and left proper;
2. The fibrant objects of this model structure are precisely the ∞ -operads.
3. The induced model structure on the slice category $dSet/\eta$ is precisely the Joyal model structure on simplicial sets [JT07, Lur06].

The existence of such a model structure was suggested in [MW07]. The ∞ -operads referred to in 2. are the dendroidal analogues of the ∞ -categories forming the fibrant objects in the Joyal model structure. They are the dendroidal sets satisfying a lifting condition analogous to the weak Kan condition of Boardman-Vogt, and were introduced in [MW07, MW09] under the name “(dendroidal) inner Kan complexes”. The dendroidal nerve of every operad is such an ∞ -operad; conversely, intuitively speaking, ∞ -operads are operads in which the composition of operations is only defined up to homotopy, in a way which is associative up to homotopy. For example, the homotopy coherent nerve of a symmetric monoidal topological category is an ∞ -operad. The theory of ∞ -operads contains the theory of ∞ -categories, as well as the theory of symmetric monoidal ∞ -categories and of operads in them. The theory of ∞ -operads is also likely to be of use in studying the notion of ∞ -category enriched in a symmetric monoidal ∞ -category (e.g. the various notions of A_∞ -categories, dg categories, weak n -categories).

The proof of our main theorem is based on three sources: First of all, we use the general methods of constructing model structures on presheaf categories developed in [Cis06] (we only use the first chapter and Section 8.1 of that book, which are both elementary). Secondly, we use some fundamental properties of dendroidal inner Kan complexes proved in [MW09]. And finally, we use some important notions and results from Joyal’s seminal paper [Joy02]: namely, the theory of join operations and the notions of left or right fibration of simplicial sets. Apart from these sources, our proof is entirely self-contained. In particular, we do not use the Joyal model structure in our proof, but instead deduce this model structure as a corollary, as expressed in 3. above.

It is known that there are several (Quillen) equivalent models for ∞ -categories: one is given by a left Bousfield localisation of the Reedy model structure on simplicial spaces and has as its fibrant objects Rezk’s complete Segal spaces; another is given by a Dwyer-Kan style model structure on topological categories established by Bergner, in which all objects are fibrant. The equivalence of these approaches is extensively discussed in Lurie’s book [Lur06]; see also [Ber07, JT07]. It is natural to ask whether analogous models exist for ∞ -operads. In two subsequent papers [CMA, CMB], we will show that this is indeed the case. We will prove there that the model structure on dendroidal sets described above is equivalent to a model structure on topological operads in which all objects are fibrant, as well as to a model structure on dendroidal spaces whose fibrant objects are “dendroidal complete Segal spaces”. The models for ∞ -categories just mentioned as well as the equivalences between them will again emerge simply by slicing over suitable unit objects of the respective monoidal structures. Together these model categories fit into a row of Quillen equivalences

$$\begin{array}{ccccc}
 sOperad & \xrightarrow{\sim} & dSet & \xrightarrow{\sim} & dSpaces \\
 \uparrow & & \uparrow & & \uparrow \\
 sCat & \xrightarrow{\sim} & sSet & \xrightarrow{\sim} & sSpaces
 \end{array}$$

in which the vertical arrows are (homotopy) full embeddings.

This paper is organized as follows. In the first section, we recall the basics about dendroidal sets. In Section 2, we state the main results of this paper: the existence of a model category structure on the category of dendroidal sets whose fibrant objects are the ∞ -operads, as well as its main properties. In Section 3, we construct this model structure through rather formal arguments. At this stage, it is clear, by construction, that the fibrant objects are ∞ -operads, but the converse is not obvious. Sections 4 and 5 provide the tools to prove that any ∞ -operad is fibrant, following the arguments which are known to hold in the case of simplicial sets for the theory of ∞ -categories. More precisely, in Section 4, we develop a dendroidal analog of Joyal’s join operations, and prove a generalization of a theorem of Joyal which ensures a right lifting property for inner Kan fibrations with respect to certain non-inner horns, under an additional hypothesis of weak invertibility of some 1-cells. In Section 5, we construct and examine a subdivision of cylinders of trees in terms of dendroidal horns. At last, in Section 6, we prove that any ∞ -operad is fibrant, and study some of the good properties of fibrations between ∞ -operads. This is done by proving an intermediate result which is important by itself: a morphism of diagrams in an ∞ -operad is weakly invertible if and only if it is locally (i.e. objectwise) weakly invertible (this is where Sections 4 and 5 have their roles to play).

We also added two appendices, which are independent of the rest of this paper. In Appendix A, we study the join operations on leaves (while in Section 4, we studied join operations on roots), and in Appendix B, we study another subdivision of cylinders of trees. In fact, these appendices can be used to provide another proof of our main results: Section 6 might have been written using Appendices A and B instead of Sections 4 and 5 respectively, without any changes (except, sometimes, replacing the evaluation by 1 by the evaluation by 0, whenever necessary). However,

these appendices are not formal consequences of the rest of these notes, and it will be useful to have this kind of results available for further work on the subject.

1. DENDROIDAL SETS

1.1. Recall from [MW07] the category of trees Ω . The objects of Ω are non-empty non-planar trees with a designated root, and given two trees T and T' , a map from T to T' is a morphism of the corresponding operads which, in these notes, we will denote by T and T' again. Hence, by definition, the category of trees is a full subcategory of the category of operads. Recall that the category $dSet$ of *dendroidal sets* is defined as the category of presheaves of sets on the category of trees Ω . Given a tree T , we denote by $\Omega[T]$ the dendroidal set represented by T .

Let 0 be the tree with only one edge, and set $\eta = \Omega[0]$. Then the category Ω/η identifies canonically with the category Δ of simplices, so that the category $dSet/\eta$ is canonically equivalent to the category $sSet$ of simplicial sets. The corresponding functor

$$(1.1.1) \quad i : \Delta \longrightarrow \Omega, \quad [n] \longmapsto i[n] = n$$

is fully faithful and its image is a sieve in Ω . This functor i induces an adjunction

$$(1.1.2) \quad i_! : sSet \rightleftarrows dSet : i^*$$

(where $i_!$ is the left Kan extension of i). Under the identification $sSet = dSet/\eta$, the functor $i_!$ is simply the forgetful functor from $dSet/\eta$ to $dSet$. The functor $i_!$ is fully faithful and makes $sSet$ into an open subtopos of $dSet$. In other words, if there is a map of dendroidal sets $X \longrightarrow Y$ with Y a simplicial set, then X has to be a simplicial set as well.

We also recall the pairs of adjoint functors

$$(1.1.3) \quad \tau : sSet \rightleftarrows Cat : N \quad \text{and} \quad \tau_d : dSet \rightleftarrows Operad : N_d$$

where N and N_d denote the nerve functors from the category of categories to the category of simplicial sets and from the category of (symmetric coloured) operads to the category of dendroidal sets.

The category of operads is endowed with a closed symmetric monoidal structure: the tensor product is defined as the Boardman-Vogt tensor product; see [MW07, Section 5]. This defines canonically a unique closed symmetric monoidal structure on the category of dendroidal sets such that the functor τ_d is symmetric monoidal, and such that, for two trees T and S , we have

$$\Omega[T] \otimes \Omega[S] = N_d(T \otimes_{BV} S),$$

where $T \otimes_{BV} S$ is the Boardman-Vogt tensor product of operads. We will denote internal Hom objects by $\mathcal{H}om(A, X)$ or by X^A .

Note that the functor $i_! : sSet \longrightarrow dSet$ is a symmetric monoidal functor, if we consider $sSet$ with its closed cartesian monoidal structure.

The functor i^* turns the category of dendroidal sets into a simplicial category; given two dendroidal sets A and X , we will write $\mathit{hom}(A, X)$ for $i^*(\mathcal{H}om(A, X))$, the simplicial set of maps from A to X .

1.2. We recall here from [MW07] the different kinds of faces of trees in Ω .

Let T be a tree.

If e is an inner edge of T , we will denote by T/e the tree obtained from T by contracting e . We then have a canonical inclusion

$$(1.2.1) \quad \partial_e : T/e \longrightarrow T.$$

A map of type (1.2.1) is called an *inner face* of T .

If v is a vertex of T , with the property that all but one of the edges incident to v are outer, we will denote by T/v the tree obtained from T by removing the vertex v and all the outer edges incident to it. We then have a canonical inclusion

$$(1.2.2) \quad \partial_v : T/v \longrightarrow T.$$

A map of type (1.2.2) is called an *outer face* of T .

A map of type (1.2.1) or (1.2.2) will be called an *elementary face* of T .

We define $\partial\Omega[T]$ as the union in $d\mathbf{Set}$ of all the images of elementary face maps $\Omega[T/x] \longrightarrow \Omega[T]$. We thus have, by definition, an inclusion

$$(1.2.3) \quad \partial\Omega[T] \longrightarrow \Omega[T].$$

Maps of shape (1.2.3) are called *boundary inclusions*. The image of a face map ∂_x will sometimes be denoted by $\partial_x(T)$ for short.

We will call *faces* the maps of Ω which are obtained, up to an isomorphism, as compositions of elementary faces. It can be checked that faces are exactly the monomorphisms in Ω ; see [MW07, Lemma 3.1].

1.3. A monomorphism of dendroidal sets $X \longrightarrow Y$ is *normal* if for any tree T , any non degenerate dendrex $y \in Y(T)$ which does not belong to the image of $X(T)$ has a trivial stabilizer $\text{Aut}(T)_y \subset \text{Aut}(T)$. A dendroidal set X is *normal* if the map $\emptyset \longrightarrow X$ is normal. For instance, for any tree T , the dendroidal set $\Omega[T]$ is normal.

Proposition 1.4. *The class of normal monomorphisms is stable by pushouts, transfinite compositions and retracts. Furthermore, this is the smallest class of maps in $d\mathbf{Set}$ which is closed under pushouts and transfinite compositions, and which contains the boundary inclusions $\partial\Omega[T] \longrightarrow \Omega[T]$, $T \in \Omega$.*

Proof. This follows from [Cis06, Proposition 8.1.35]. □

Proposition 1.5. *A monomorphism of dendroidal sets $X \longrightarrow Y$ is normal if and only if for any tree T , the action of $\text{Aut}(T)$ on $Y(T) - X(T)$ is free.*

Proof. It is easily seen that the class of monomorphisms which satisfy the above property is stable by pushouts and transfinite compositions, and contains the boundary inclusions $\partial\Omega[T] \longrightarrow \Omega[T]$. It thus follows from the preceding proposition that any normal monomorphism has this property. But it is also obvious that any monomorphism with this property is normal. □

Corollary 1.6. *A dendroidal set X is normal if and only if for any tree T , the action of the group $\text{Aut}(T)$ on $X(T)$ is free.*

Corollary 1.7. *Given any map of dendroidal sets $X \longrightarrow Y$, if Y is normal, then X is normal.*

Corollary 1.8. *Any monomorphism $i : A \longrightarrow B$ with B normal is a normal monomorphism.*

Proposition 1.9. *Let $A \longrightarrow B$ and $X \longrightarrow Y$ be two normal monomorphisms. The induced map*

$$A \otimes Y \amalg_{A \otimes X} B \otimes X \longrightarrow B \otimes Y$$

is a normal monomorphism.

Proof. As the class of normal monomorphisms is generated by the boundary inclusions, it is sufficient to check this property in this case; see e.g. [Hov99, Lemma 4.2.4].

Consider now two trees S and T . We have to show that the map

$$\partial\Omega[S] \otimes \Omega[T] \amalg_{\partial\Omega[S] \otimes \partial\Omega[T]} \Omega[S] \otimes \partial\Omega[T] \longrightarrow \Omega[S] \otimes \Omega[T]$$

is a normal monomorphism. But as $\Omega[S] \otimes \Omega[T]$ is the dendroidal nerve of the Boardman-Vogt tensor product of S and T , which is Σ -free, it is a normal dendroidal set. Hence we are reduced to prove that the above map is a monomorphism. This latter property is equivalent to the fact that the commutative square

$$\begin{array}{ccc} \partial\Omega[S] \otimes \partial\Omega[T] & \longrightarrow & \partial\Omega[S] \otimes \Omega[T] \\ \downarrow & & \downarrow \\ \Omega[S] \otimes \partial\Omega[T] & \longrightarrow & \Omega[S] \otimes \Omega[T] \end{array}$$

is a pullback square in which any map is a monomorphism. As the nerve functor preserves pullbacks, this reduces to the following property: for any elementary faces $S/x \longrightarrow S$ and $T/y \longrightarrow T$ the commutative square

$$\begin{array}{ccc} S/x \otimes_{BV} T/y & \longrightarrow & S/x \otimes_{BV} T \\ \downarrow & & \downarrow \\ S \otimes_{BV} T/y & \longrightarrow & S \otimes_{BV} T \end{array}$$

is a pullback square of monomorphisms in the category of operads. This is an elementary consequence of the definitions involved. \square

1.10. Under the assumptions of Proposition 1.9, we shall write $A \otimes Y \cup B \otimes X$ instead of $A \otimes Y \amalg_{A \otimes X} B \otimes X$.

2. STATEMENT OF MAIN RESULTS

In this section, we state the main results of this paper.

2.1. Recall from [MW09, Section 5] the notion of *inner horn*. Given an inner edge e in a tree T , we get an inclusion

$$(2.1.1) \quad \Lambda^e[T] \longrightarrow \Omega[T],$$

where $\Lambda^e[T]$ is obtained as the union of all the images of elementary face maps which are distinct from the face $\partial_e : T/e \longrightarrow T$. The maps of shape (2.1.1) are called *inner horn inclusions*.

A map of dendroidal sets is called an *inner anodyne extension* if it belongs to the smallest class of maps which is stable by pushouts, transfinite composition and retracts, and which contains the inner horn inclusions.

A map of dendroidal sets is called an *inner Kan fibration* if it has the right lifting property with respect to the class of inner anodyne extensions (or, equivalently, to the set of inner horn inclusions).

A dendroidal set X is an *inner Kan complex* if the map from X to the terminal dendroidal set is an inner Kan fibration. We will also call inner Kan complexes ∞ -operads. For example, for any operad \mathcal{P} , the dendroidal set $N_d(\mathcal{P})$ is an ∞ -operad; see [MW09, Proposition 5.3]. In particular, for any tree T , the dendroidal set $\Omega[T]$ is an ∞ -operad. For a simplicial set K , its image by $i_!$ is an ∞ -operad if and only if K is an ∞ -category (i.e. K is a quasi-category in the sense of [Joy02]).

A map of dendroidal sets will be called a *trivial fibration* if it has the right lifting property with respect to normal monomorphisms.

Note that the small object argument implies that we can factor any map of dendroidal sets into a normal monomorphism followed by a trivial fibration (resp. into an inner anodyne extension followed by an inner Kan fibration).

Remark 2.2. A morphism between normal dendroidal sets is a trivial fibration if and only if it has the right lifting property with respect to monomorphisms: this follows immediately from Corollaries 1.7 and 1.8.

2.3. Recall the naive model structure on the category of operads [Wei07]: the weak equivalences are the equivalences of operads, i.e. the maps $f : \mathcal{P} \rightarrow \mathcal{Q}$ which are fully faithful and essentially surjective: for any $n + 1$ -uple of objects (a_1, \dots, a_n, a) in \mathcal{P} , f induces a bijection

$$\mathcal{P}(a_1, \dots, a_n; a) \rightarrow \mathcal{Q}(f(a_1), \dots, f(a_n); f(a)),$$

and any object of \mathcal{Q} is isomorphic to the image of some object in \mathcal{P} . The fibrations are *operadic fibrations*, i.e. the maps $f : \mathcal{P} \rightarrow \mathcal{Q}$ such that, given any isomorphism $\beta : b_0 \rightarrow b_1$ in \mathcal{Q} , and any object a_1 in \mathcal{P} such that $f(a_1) = b_1$, there exists an isomorphism $\alpha : a_0 \rightarrow a_1$ in \mathcal{P} , such that $f(\alpha) = \beta$.

This model structure is closely related with the naive model structure on Cat (for which the weak equivalences are the equivalences of categories). In fact, the latter can be recovered from the one on operads by slicing over the unit operad (which is also the terminal category). The fibrations of the naive model structure on Cat will be called the *categorical fibrations*.

Theorem 2.4. *The category of dendroidal sets is endowed with a model category structure for which the cofibrations are the normal monomorphisms, the fibrant objects are the ∞ -operads, and the fibrations between fibrant objects are the inner Kan fibrations between ∞ -operads whose image by τ_d is an operadic fibration. The class of weak equivalences is the smallest class of maps of dendroidal sets \mathbb{W} which satisfies the following three properties.*

- (a) (*'2 out 3 property'*) *In any commutative triangle, if two maps are in \mathbb{W} , then so is the third.*
- (b) *Any inner anodyne extension is in \mathbb{W} .*
- (c) *Any trivial fibration between ∞ -operads is in \mathbb{W} .*

Proof. This follows from Proposition 3.12, Theorem 6.10, and Corollary 6.11. \square

Corollary 2.5. *The adjunction $\tau_d : d\mathit{Set} \rightleftarrows \mathit{Operad} : N_d$ is a Quillen pair. Moreover, the two functors τ_d and N_d both preserve weak equivalences. In particular, a morphism of operads is an equivalence of operads if and only if its dendroidal nerve is a weak equivalence.*

Proof. See 6.17. \square

Proposition 2.6. *The model category structure of Theorem 2.4 has the following additional properties:*

- (a) *it is left proper;*
- (b) *it is cofibrantly generated (it is even combinatorial);*
- (c) *it is symmetric monoidal.*

Proof. See Propositions 3.12 and 3.17. □

Corollary 2.7. *For any normal dendroidal set A and any ∞ -operad X , the set of maps $[A, X] = \mathrm{Hom}_{\mathbf{Ho}(\mathcal{dSet})}(A, X)$ is canonically identified with the set of isomorphism classes of objects in the category $\tau\mathit{hom}(A, X)$.*

Proof. See Proposition 6.20. □

Corollary 2.8. *Let $f : X \rightarrow Y$ be a morphism of ∞ -operads. The following conditions are equivalent.*

- (a) *The map $f : X \rightarrow Y$ is a weak equivalence.*
- (b) *For any normal dendroidal set A , the map*

$$\tau_d \mathcal{H}\mathrm{om}(A, X) \longrightarrow \tau_d \mathcal{H}\mathrm{om}(A, Y)$$

is an equivalence of operads.

- (c) *For any normal dendroidal set A , the map*

$$\tau\mathit{hom}(A, X) \longrightarrow \tau\mathit{hom}(A, Y)$$

is an equivalence of categories.

Proof. Remember that, by definition (and any ∞ -operad being fibrant), the map f is a weak equivalence if and only if, for any normal dendroidal set A , the induced map

$$[A, X] \longrightarrow [A, Y]$$

is bijective. This corollary is thus a direct consequence of Corollaries 2.5 and 2.7 and of the fact the model category structure on \mathcal{dSet} is monoidal. □

Corollary 2.9. *Let $u : A \rightarrow B$ be a morphism of normal dendroidal sets. The following conditions are equivalent.*

- (a) *The map $u : A \rightarrow B$ is a weak equivalence.*
- (b) *For any ∞ -operad X , the map*

$$\tau_d \mathcal{H}\mathrm{om}(B, X) \longrightarrow \tau_d \mathcal{H}\mathrm{om}(A, X)$$

is an equivalence of operads.

- (c) *For any ∞ -operad X , the map*

$$\tau\mathit{hom}(B, X) \longrightarrow \tau\mathit{hom}(A, X)$$

is an equivalence of categories.

Proof. The fibrant objects of \mathcal{dSet} are exactly the ∞ -operads. Hence, the map $u : A \rightarrow B$ is a weak equivalence if and only if, for any ∞ -operad X , the map

$$[B, X] \longrightarrow [A, X]$$

is bijective. We conclude the proof using the same arguments as in the proof of Corollary 2.8. □

Corollary 2.10 (Joyal). *The category of simplicial sets is endowed with a left proper, cofibrantly generated, symmetric monoidal model category structure for which the cofibrations are the monomorphisms, the fibrant objects are the ∞ -categories, and the fibrations between fibrant objects are the inner Kan fibrations between ∞ -categories whose image by τ is a categorical fibration.*

Proof. The model category structure on $dSet$ induces a model category structure on $dSet/\eta \simeq sSet$; see also Remark 3.14 for $B = \eta$. \square

Remark 2.11. Note that, the functor $i_! : sSet \rightarrow dSet$ is fully faithful and symmetric monoidal. Moreover, for any simplicial sets A and X , we have $hom(i_!(A), i_!(X)) = X^A$. We deduce from this that the induced map

$$\mathrm{Hom}_{\mathbf{Ho}(sSet)}(A, X) \longrightarrow \mathrm{Hom}_{\mathbf{Ho}(dSet)}(i_!(A), i_!(X))$$

is bijective (where $\mathbf{Ho}(sSet)$ denotes the homotopy category of the Joyal model structure, given by Corollary 2.10). As a consequence, we also have formally the simplicial analogs of Corollaries 2.7, 2.8 and 2.9.

3. CONSTRUCTION OF AN ABSTRACT MODEL CATEGORY FOR ∞ -OPERADS

This section is devoted to the construction of a model category structure on $dSet$. The construction is relatively formal and uses very little of the theory of dendroidal sets. By definition, we will have that any fibrant object of this model category is an ∞ -operad. The proof of the converse (any ∞ -operad is fibrant) is the ‘raison d’être’ of the next sections.

Proposition 3.1. *Let $A \rightarrow B$ and $X \rightarrow Y$ be an inner anodyne extension and a normal monomorphism respectively. The induced map*

$$A \otimes Y \cup B \otimes X \longrightarrow B \otimes Y$$

is an inner anodyne extension.

Proof. Using [Cis06, Corollary 1.1.8], we see that it is sufficient to check this property when $A \rightarrow B$ is an inner horn inclusion and when $X \rightarrow Y$ is a boundary inclusion. This proposition thus follows from [MW09, Proposition 9.2]. \square

3.2. We denote by J the nerve of the contractible groupoid with two objects 0 and 1 (i.e. J is the nerve of the fundamental groupoid of $\Delta[1]$). We will write $J_d = i_!(J)$ for the corresponding dendroidal set.

A morphism of dendroidal sets is a *J-anodyne extension* if it belongs to the smallest class of maps which contains the inner anodyne extensions and the maps

$$\partial\Omega[T] \otimes J_d \cup \Omega[T] \otimes \{e\} \longrightarrow \Omega[T] \otimes J_d \quad T \in \Omega, e = 0, 1, ,$$

and which is closed under pushouts, transfinite compositions and retracts.

A morphism of dendroidal sets will be called a *J-fibration* if it has the right lifting property with respect to *J-anodyne extensions*.

A dendroidal set X is *J-fibrant* if the map from X to the terminal dendroidal set is a *J-fibration*.

Proposition 3.3. *Let $A \rightarrow B$ and $X \rightarrow Y$ be a J-anodyne extension and a normal monomorphism respectively. The induced map*

$$A \otimes Y \cup B \otimes X \longrightarrow B \otimes Y$$

is a J-anodyne extension.

Proof. Using [Cis06, Corollary 1.1.8], this follows formally from the definition and from Proposition 3.1. \square

3.4. Let B be a dendroidal set. Denote by \mathbf{An}_B the class of maps of \mathbf{dSet}/B whose image in \mathbf{dSet} is J -anodyne. For each dendroidal set X over B , with structural map $a : X \rightarrow B$, we define a cylinder of X over B

$$(3.4.1) \quad \begin{array}{ccc} X \amalg X & \xrightarrow{(\partial_X^0, \partial_X^1)} & J_d \otimes X \xrightarrow{\sigma_X} X \\ & \searrow (a, a) & \downarrow a' \\ & & B \end{array}$$

in which ∂_X^e is the tensor product of $\{e\} \rightarrow J_d$ with 1_X , while σ_X is the tensor product of $J_d \rightarrow \eta$ with 1_X , and a' is the composition of $1_{J_d} \otimes a$ with the map σ_B .

These cylinders over B define the notion J -homotopy over B (or *fiberwise J -homotopy*) between maps in \mathbf{dSet}/B . Given two dendroidal sets A and X over B , we define $[A, X]_B$ as the quotient of the set $\mathrm{Hom}_{\mathbf{dSet}/B}(A, X)$ by the equivalence relation generated by the relation of J -homotopy over B . A morphism $A \rightarrow A'$ of dendroidal sets over B is a B -equivalence if, for any dendroidal set X over B such that the structural map $X \rightarrow B$ is a J -fibration, the map

$$[A', X]_B \rightarrow [A, X]_B$$

is bijective.

In the case B is normal, any monomorphism over B is normal; see Corollaries 1.7 and 1.8. We see from Proposition 3.3 and from [Cis06, Lemma 1.3.52] that the class \mathbf{An}_B is a class of anodyne extensions with respect to the functorial cylinder (3.4.1) in the sense of [Cis06, Definition 1.3.10]. In other words, the functorial cylinder (3.4.1) and the class \mathbf{An}_B form a *homotopical structure* on the category \mathbf{dSet}/B in the sense of [Cis06, Definition 1.3.14]. As a consequence, a direct application of [Cis06, Theorem 1.3.22, Proposition 1.3.36 and Lemma 1.3.52] leads to the following statement¹.

Proposition 3.5. *For any normal dendroidal set B , the category \mathbf{dSet}/B of dendroidal sets over B is endowed with a left proper cofibrantly generated model category structure for which the weak equivalences are the B -equivalences, the cofibrations are the monomorphisms, and the fibrant objects are the dendroidal sets X over B such that the structural map is a J -fibration. Moreover, a morphism between fibrant objects is a fibration in \mathbf{dSet}/B if and only if its image in \mathbf{dSet} is a J -fibration.*

Remark 3.6. Any J -anodyne extension over B is a trivial cofibration in the model structure of the preceding proposition; see [Cis06, Proposition 1.3.31].

Lemma 3.7. *Let $p : X \rightarrow Y$ be a trivial fibration between normal dendroidal sets. Any section $s : Y \rightarrow X$ is a J -anodyne extension.*

Proof. This is a particular case of [Cis06, Corollary 1.3.35] applied to the homotopical structure defined in 3.4 on \mathbf{dSet}/Y . \square

¹The results of [Cis06] are stated for presheaves categories, so that, strictly speaking, to apply them, we implicitly use the canonical equivalence of categories between \mathbf{dSet}/B and the category of presheaves on Ω/B .

3.8. We fix once and for all a normalization E_∞ of the terminal dendroidal set: i.e., we choose a normal dendroidal set E_∞ such that the map from E_∞ to the terminal dendroidal set is a trivial fibration.

Lemma 3.9. *For any normal dendroidal set X , and any map $a : X \rightarrow E_\infty$, the map $(a, 1_X) : X \rightarrow E_\infty \times X$ is a J -anodyne extension.*

Proof. This follows immediately from Lemma 3.7 because $(a, 1_X)$ is a section of the projection $X \times E_\infty \rightarrow X$, which is a trivial fibration by definition of E_∞ . \square

Lemma 3.10. *Let $i : A \rightarrow B$ be a morphism of normal dendroidal sets, and $p : X \rightarrow Y$ a morphism of dendroidal sets. The map p has the right lifting property with respect to i in $dSet$ if and only if, for any morphism $B \rightarrow E_\infty$, the map $1_{E_\infty} \times p$ has the right lifting property with respect to i in $dSet/E_\infty$.*

Proof. Suppose that $1_{E_\infty} \times p$ has the right lifting property with respect to i , and consider the lifting problem below.

$$\begin{array}{ccc} A & \xrightarrow{a} & X \\ i \downarrow & \nearrow \ell & \downarrow p \\ B & \xrightarrow{b} & Y \end{array}$$

As B is normal, there exists a map $\beta : B \rightarrow E_\infty$. If we write $\alpha = \beta i$, we see immediately that the lifting problem above is now equivalent to the lifting problem

$$\begin{array}{ccc} A & \xrightarrow{(\alpha, a)} & E_\infty \times X \\ i \downarrow & \nearrow (\beta, \ell) & \downarrow 1_{E_\infty} \times p \\ B & \xrightarrow{(\beta, b)} & E_\infty \times Y \end{array}$$

and this proves the lemma. \square

3.11. Given a normal dendroidal set A and a J -fibrant dendroidal set X , we denote by $[A, X]$ the quotient of $\text{Hom}_{dSet}(A, X)$ by the equivalence relation generated by the J -homotopy relation (i.e., with the notations of 3.4, $[A, X] = [A, X]_e$, where e denotes the terminal dendroidal set).

Proposition 3.12. *The category of dendroidal sets is endowed with a left proper cofibrantly generated model category in which the cofibrations are the normal monomorphisms, the fibrant objects are the J -fibrant dendroidal sets, and the fibrations between fibrant objects are the J -fibrations. Furthermore, given a normal dendroidal set A and a J -fibrant dendroidal set X , we have a canonical identification*

$$[A, X] = \text{Hom}_{\mathbf{Ho}(dSet)}(A, X).$$

Proof. Proposition 3.5 applied to $B = E_\infty$ gives us a model category structure on $dSet/E_\infty$. Consider the adjunction

$$p_! : dSet/E_\infty \rightleftarrows dSet : p^*,$$

where p^* is the functor $X \mapsto E_\infty \times X$. It follows obviously from Lemma 3.9 that the functor $p^*p_!$ is a left Quillen equivalence from the category $dSet/E_\infty$ to itself. This implies immediately that the adjunction $(p_!, p^*)$ satisfies all the necessary hypotheses to define a model structure on $dSet$ by transfer; see e.g. [Cra95]

or [Cis06, Proposition 1.4.23]. In other words, the category of dendroidal sets is endowed with a cofibrantly generated model category structure for which the weak equivalences (resp. the fibrations) are the maps whose image by p^* is a weak equivalence (resp. a fibration) in \mathcal{dSet}/E_∞ . The description of cofibrations follows from Proposition 1.4. We know that the fibrations between fibrant objects in \mathcal{dSet}/E_∞ are the maps whose image in \mathcal{dSet} is a J -fibration; see Proposition 3.5. The description of fibrant objects and of fibrations between fibrant objects in \mathcal{dSet} as J -fibrant objects and J -fibrations is thus a direct consequence of Lemma 3.10. The identification $[A, X] = \text{Hom}_{\mathbf{Ho}(\mathcal{dSet})}(A, X)$ is obtained from the general description of the set of maps from a cofibrant object to a fibrant object in an abstract model category. It remains to prove left properness: this follows from the left properness of the model category structure of Proposition 3.5 for $B = E_\infty$ (which is obvious, as any object over E_∞ is cofibrant), and from the fact that p^* preserves cofibrations as well as colimits, while it preserves and detects weak equivalences. \square

3.13. The weak equivalences of the model structure defined in Proposition 3.12 will be called the *weak operadic equivalences*.

Given a dendroidal set A , a *normalization* of A is a trivial fibration $A' \rightarrow A$ with A' normal. For instance, the projection $E_\infty \times A \rightarrow A$ is a normalization of A (as E_∞ is normal, it follows from Corollary 1.7 that $E_\infty \times A$ is normal). For a morphism of dendroidal sets $f : A \rightarrow B$, the following conditions are equivalent.

- (a) The map f is a weak operadic equivalence.
- (b) For any commutative square

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B \end{array}$$

in which the horizontal maps are normalizations, and for any J -fibrant dendroidal set X , the map $[B', X] \rightarrow [A', X]$ is bijective.

- (c) There exists a commutative square

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B \end{array}$$

in which the horizontal maps are normalizations such that, for any J -fibrant dendroidal set X , the map $[B', X] \rightarrow [A', X]$ is bijective.

Remark 3.14. Given a normal J -fibrant dendroidal set B , the model structure induced on \mathcal{dSet}/B by the model structure of Proposition 3.12 coincide with the model structure of Proposition 3.5 (this follows, for instance, from the fact these model structures have the same cofibrations and fibrations between fibrant objects).

Remark 3.15. The model category structure of Proposition 3.12 is cofibrantly generated. The generating cofibrations are the inclusions of shape $\partial\Omega[T] \rightarrow \Omega[T]$ for any tree T . We don't know any explicit set of generating trivial cofibrations. However, we know (from the proof of Proposition 3.12) that there exists a generating set of trivial cofibrations \mathcal{J} for the model structure on \mathcal{dSet}/E_∞ , such that

$p_!(\mathcal{J})$ is a generating set of trivial cofibrations of $dSet$. In particular, there exists a generating set of trivial cofibrations of $dSet$ which consists of trivial cofibrations between normal dendroidal sets. Statements about trivial cofibrations will often be reduced to statements about J -anodyne extensions using the following argument.

Proposition 3.16. *The class of trivial cofibrations between normal dendroidal sets is the smallest class C of monomorphisms between normal dendroidal sets which contains J -anodyne extensions, and such that, given any monomorphisms between normal dendroidal sets*

$$A \xrightarrow{i} B \xrightarrow{j} C,$$

if j and ji are in C , so is i .

Proof. Let $i : A \rightarrow B$ be a monomorphism between normal dendroidal sets. As B is normal, we can choose a map from B to E_∞ . We can then choose a commutative diagram over E_∞

$$\begin{array}{ccc} A & \xrightarrow{a} & A' \\ i \downarrow & & \downarrow i' \\ B & \xrightarrow{b} & B' \end{array}$$

in which a and b are J -anodyne extensions, A' and B' are fibrant in $dSet/E_\infty$, and i' is a monomorphism: this follows, for instance, from the fact that any J -fibrant resolution functor constructed with the small object argument applied to the generating set of J -anodyne extensions preserves monomorphisms; see [Cis06, Proposition 1.2.35]. Applying [Cis06, Corollary 1.3.35] to the model structure of Proposition 3.5 for $B = E_\infty$, we see that i is a trivial cofibration if and only if i' is a J -anodyne extension. This proves the proposition. \square

Proposition 3.17. *The model category structure on $dSet$ is symmetric monoidal.*

Proof. As we already know that normal monomorphisms are well behaved with respect to the tensor product (Proposition 1.9) it just remains to prove that, given a normal monomorphism $i : A \rightarrow B$ and a trivial cofibration $j : C \rightarrow D$, the induced map

$$A \otimes D \cup B \otimes C \rightarrow B \otimes D$$

is a trivial cofibration. According to [Hov99, Lemma 4.2.4], we can assume that i is a generating cofibration, and j a generating trivial cofibration. In particular, we can assume that i and j are monomorphisms between normal dendroidal sets; see Remark 3.14. It is thus sufficient to prove that, given a normal dendroidal set A , the functor $X \mapsto A \otimes X$ preserves trivial cofibrations between normal dendroidal sets. By Proposition 3.16, it is even sufficient to prove that tensor product by A preserves J -anodyne extensions, which follows from Proposition 3.3. \square

4. THE JOIN OPERATION ON TREES

The aim of this section is to study a dendroidal analog of the join operations on simplicial sets introduced by Joyal in [Joy02]. We shall prove a generalization of [Joy02, Theorem 2.2]; see Theorem 4.2.

4.1. Let X be a ∞ -operad. A 1-simplex of X (i.e. a map $\Delta[1] \rightarrow i^*(X)$) will be called *weakly invertible* if the corresponding morphism in the category $\tau(i^*(X))$ is an isomorphism.

Note that, for any ∞ -operad X , the category $\tau(i^*(X))$ is canonically isomorphic to the category underlying the operad $\tau_d(X)$: this comes from the explicit description of $\tau(i^*(X))$ given by Boardman and Vogt (see [Joy02, Proposition 1.2]) and from its dendroidal generalization, which describes $\tau_d(X)$ explicitly; see [MW09, Proposition 6.10]. As a consequence, weakly invertible 1-cells in X can be described as the maps $i_! \Delta[1] = \Omega[1] \rightarrow X$ which induce invertible morphisms in the underlying category of the operad $\tau_d(X)$.

Theorem 4.2. *Let T be a tree with at least two vertices as well as a unary vertex r at the root, and let $p : X \rightarrow Y$ be an inner Kan fibration between ∞ -operads. Then any solid commutative square of the form*

$$\begin{array}{ccc} \Lambda^r[T] & \xrightarrow{f} & X \\ \downarrow & \nearrow h & \downarrow p \\ \Omega[T] & \xrightarrow{g} & Y \end{array}$$

in which $f(r)$ is weakly invertible in X has a diagonal filling h .

4.3. In order to prove this theorem, we will introduce join operations on forests.

A *forest* is a finite set of trees (i.e. of objects of Ω). Given a forest $\mathcal{T} = (T_1, \dots, T_k)$, $k \geq 0$, we write $\mathcal{T}/dSet$ for the category of dendroidal sets under the coproduct $\Omega[\mathcal{T}] = \coprod_{i=1}^k \Omega[T_i]$. The objects of $\mathcal{T}/dSet$ are thus of shape $(X, x_i) = (X, x_1, \dots, x_k)$, where X is a dendroidal set, and $x_i \in X(T_i)$, for $1 \leq i \leq k$. Morphisms $(X, x_i) \rightarrow (Y, y_i)$ are maps $f : X \rightarrow Y$ such that $f(x_i) = y_i$ for all i , $1 \leq i \leq k$.

Given an integer $n \geq 0$, we construct the tree $\mathcal{T} \star n$ by joining the trees T_1, \dots, T_k together over a new vertex v , and then grafting the result onto $i[n]$ (i.e. onto $[n]$ viewed as a tree).

$$(4.3.1) \quad (T_1, \dots, T_k) \star n = \begin{array}{c} \begin{array}{ccc} T_1 & & T_2 & & \dots & & T_k \\ & \swarrow & & \swarrow & & \swarrow & \\ & a_1 & & a_2 & & & a_k \\ & & v & & & & \\ & & | & & & & \\ & & 0 & & & & \\ & & | & & & & \\ & & 1 & & & & \\ & & \vdots & & & & \\ & & n & & & & \end{array} \end{array}$$

We insist that the forest \mathcal{T} might be empty: for $k = 0$, we have

$$(4.3.2) \quad () \star n = \begin{array}{c} v \\ | \\ 0 \\ | \\ 1 \\ \vdots \\ n \end{array}$$

As each T_i , $1 \leq i \leq k$, embeds canonically into $\mathcal{T} \star n$, we can view $\Omega[\mathcal{T} \star n]$ as an object of $\mathcal{T}/dSet$. One checks that there is a unique functor

$$\Delta \longrightarrow \Omega, \quad [n] \longmapsto \mathcal{T} \star n$$

such that the inclusions $T_i \longrightarrow \mathcal{T} \star n$ are functorial in T_i and such that the canonical inclusion $i[n] \longrightarrow \mathcal{T} \star n$ is functorial in $[n]$. This defines a functor

$$(4.3.3) \quad \mathcal{T} \star (-) : \Delta \longrightarrow \mathcal{T}/dSet.$$

By Kan extension, we obtain a colimit preserving functor which extends (4.3.3):

$$(4.3.4) \quad \mathcal{T} \star (-) : sSet \longrightarrow \mathcal{T}/dSet.$$

We have $\mathcal{T} \star \Delta[n] = \Omega[\mathcal{T} \star n]$. The functor (4.3.4) has a right adjoint

$$(4.3.5) \quad \mathcal{T} \setminus (-) : \mathcal{T}/dSet \longrightarrow sSet.$$

For a one tree forest $\mathcal{T} = (T)$, we will simply write $\mathcal{T} \star K = T \star K$ and $\mathcal{T} \setminus X = T \setminus X$ for any simplicial set K and any dendroidal set X under $\Omega[T]$. Under these conventions, these operations extend the join operations introduced by Joyal in [Joy02] in the sense that we have the following formulas.

$$\begin{aligned} i[n] \star i_1(K) &= i_1(\Delta[n] \star K) \\ i[n] \setminus i_1(L) &= i_1(\Delta[n] \setminus L) \end{aligned}$$

Note that the inclusions $\Omega[n] \longrightarrow \mathcal{T} \star \Delta[n]$ in $dSet$ induce a natural projection map

$$(4.3.6) \quad \pi_X : \mathcal{T} \setminus X \longrightarrow i^*(X)$$

for any dendroidal set X under \mathcal{T} .

Remark 4.4. Note that any tree with at least one vertex T is obtained by joining a forest with an ordinal, i.e. as $T = \mathcal{T} \star n$ for some forest \mathcal{T} and some integer $n \geq 0$. A tree T has at least two vertices and a unary vertex at the root (as in the statement of Theorem 4.2) if and only if there exists a forest \mathcal{T} such that $T = \mathcal{T} \star 1$.

4.5. In order to prove Theorem 4.2, we will have also to consider some specific maps of forests. For this purpose, we introduce the following terminology.

Let T be a tree. A set A of edges in T is called *admissible* if, for any input edge e of T , and any vertex v in T , if A contains a path (branch) from e to v , then A contains all the edges above v .

If A is an admissible set of edges in T , we will define a forest $\partial_A(T)$, and for each tree S in $\partial_A(T)$, a face map $S \longrightarrow T$ in the category Ω . Roughly speaking, one deletes from T all edges in A , and defines $\partial_A(T)$ as the resulting connected components. A formal definition is by induction on the cardinality of A .

- (i) If A is empty, then $\partial_A(T) = T$.
- (ii) If A contains the root edge e of T , let T_1, \dots, T_k be the trees obtained from T by deleting e and the vertex immediately above it, let $A_i = T_i \cap A$, and define $\partial_A(T)$ as the union of the forests $\partial_{A_i}(T_i)$, $1 \leq i \leq k$.
- (iii) If A contains an input edge a of T , it must contain all the edges above the vertex v just below a . Let $T_{(v)}$ be the tree obtained from T by pruning away v and all the edges above it. Let $A_{(v)} = T_{(v)} \cap A$, and define $\partial_A(T) = \partial_{A_{(v)}}(T_{(v)})$.
- (iv) If A contains an inner edge a of T , let T/a be the tree obtained by contracting a , and define $\partial_A(T)$ to be $\partial_{A-\{a\}}(T/a)$.

One can check that the steps (i)–(iv) can be performed in any order, so that the forest $\partial_A(T)$ is well defined. Each tree S in this forest $\partial_A(T)$ is a face of T , hence comes with a canonical map $S \rightarrow T$.

Example 4.6. The tree

has two input edges c and d . The edges b and c form a path from c down to v . So any admissible set A which contains b and c , for example, must contain d and e as well.

4.7. This construction extends to forests in the following way. Let $\mathcal{T} = (T_1, \dots, T_k)$ be a forest. An *admissible subset of edges* A in \mathcal{T} is a k -tuple $A = (A_1, \dots, A_k)$, where A_i is an admissible set of edges of T_i for $1 \leq i \leq k$. We can then define the forest $\partial_A(\mathcal{T})$ as the union of the forests $\partial_{A_i}(T_i)$. Given any integer $n \geq 0$, we have a canonical map

$$(4.7.1) \quad \partial_A(\mathcal{T}) \star n \longrightarrow \mathcal{T} \star n$$

which is characterized by the fact that, given any tree S in some $\partial_{A_i}(T_i)$, for $1 \leq i \leq k$, the diagram

$$(4.7.2) \quad \begin{array}{ccc} S \star n & \longrightarrow & T_i \star n \\ \downarrow & & \downarrow \\ \partial_A(\mathcal{T}) \star n & \longrightarrow & \mathcal{T} \star n \end{array}$$

commutes. The map (4.7.1) is a monomorphism of trees in Ω and is natural in $[n]$ (as an object of Δ). More generally, given an inclusion $A \subset B$ between admissible subsets of edges in \mathcal{T} , we have canonical monomorphisms of trees

$$(4.7.3) \quad \partial_B(\mathcal{T}) \star n \longrightarrow \partial_A(\mathcal{T}) \star n$$

(which is just another instance of (4.7.1) for the forest $\partial_A(\mathcal{T})$ with admissible subset of edges given by the sets $B_i \cap \partial_{A_i}(T_i)$). The maps (4.7.3) define a contravariant functor from the set of admissible subsets of edges in \mathcal{T} (partially ordered by inclusion) to Ω . Given an inclusion $A \subset B$ of admissible subsets of edges in \mathcal{T} , there exists a unique morphism

$$(4.7.4) \quad \Omega[\partial_B(\mathcal{T})] \longrightarrow \Omega[\partial_A(\mathcal{T})]$$

such that the following diagram commutes for any simplicial set K .

$$(4.7.5) \quad \begin{array}{ccc} \Omega[\partial_B(\mathcal{T})] & \longrightarrow & \Omega[\partial_A(\mathcal{T})] \\ \downarrow & & \downarrow \\ \partial_B(\mathcal{T}) \star K & \longrightarrow & \partial_A(\mathcal{T}) \star K \end{array}$$

By adjunction, we also have natural morphisms

$$(4.7.6) \quad \partial_B(\mathcal{T}) \setminus X \longrightarrow \partial_A(\mathcal{T}) \setminus X$$

for all dendroidal sets X under $\Omega[\partial_A(\mathcal{T})]$.

Example 4.8. If a is the root of T , and if T is obtained by grafting trees T_i with root edges a_i onto a corolla, then the map of type (4.7.3) for $A = \emptyset$ and $B = \{a\}$ is the map ∂_a given by contracting a :

4.9. We will now study an elementary combinatorial situation which we will have to consider twice to prove Theorem 4.2: in the proof of Proposition 4.11 and in the proof of 4.15.2.

Consider a tree T . Assume that $T = \mathcal{T} \star n$ for a non-empty forest $\mathcal{T} = (T_1, \dots, T_k)$ and an ordinal $[n]$, $n > 0$.

Let i , $0 \leq i < n$, be an integer, and $\{A_1, \dots, A_s\}$, $s \geq 1$, a finite family of admissible subsets of edges in \mathcal{T} . Define

$$C \subset D \subset \Omega[T]$$

by

$$C = \left(\bigcup_{r=1}^s \partial_{A_r}(\mathcal{T}) \star \Lambda^i[n] \right) \cup \Omega[n] \quad \text{and} \quad D = \bigcup_{r=1}^s \partial_{A_r}(\mathcal{T}) \star \Delta[n],$$

where $\Omega[n]$ is considered as a subcomplex of $\Omega[T]$ through the canonical map.

Lemma 4.10. *Under the assumptions of 4.9, the map $C \rightarrow D$ is an inner anodyne extension.*

Proof. If \mathcal{T} is the empty forest, we must have $s = 1$ and $A_1 = \emptyset$, so that $D = \Omega[T]$, and $C = \Lambda^i[T]$ is an inner horn. From now on, we will assume that \mathcal{T} is non-empty.

Given a forest \mathcal{T}' , the number of edges in \mathcal{T}' is simply defined as the sum of the number of edges in each of the trees which occur in \mathcal{T}' . For each integer $p \geq 0$, write \mathcal{F}_p for the set of faces F which belong to D but not to C , and which are of shape $F = \Omega[\partial_A(\mathcal{T}) \star n]$ for an admissible subset of edges A in \mathcal{T} , such that $\partial_A(\mathcal{T})$ has exactly p edges.

Define a filtration

$$C = C_0 \subset C_1 \subset \dots \subset C_p \subset \dots \subset D$$

by

$$C_p = C_{p-1} \cup \bigcup_{F \in \mathcal{F}_p} F, \quad p \geq 1.$$

We have $D = C_p$ for p big enough, and it is sufficient to prove that the inclusions $C_{p-1} \rightarrow C_p$ are inner anodyne for $p \geq 1$. If F and F' are in \mathcal{F}_p , then $F \cap F'$ is in C_{p-1} . Moreover, if $F = \Omega[\partial_A(\mathcal{T}) \star n]$ for an admissible subset of edges A , then we have

$$F \cap C_{p-1} = \Lambda^i[\partial_A(\mathcal{T}) \star n],$$

which is an inner horn. Hence we can describe the inclusion $C_{p-1} \longrightarrow C_p$ as a finite composition of pushouts by inner horn inclusions of shape $F \cap C_{p-1} \longrightarrow F$ for $F \in \mathcal{F}_p$. \square

Proposition 4.11. *Let $\mathcal{T} = (T_1, \dots, T_k)$ be a forest, and $n \geq 1$, $0 \leq i < n$, be integers. The inclusion $(\mathcal{T} \star \Lambda^i[n]) \cup \Omega[n] \longrightarrow \mathcal{T} \star \Delta[n]$ is an inner anodyne extension.*

Proof. This is a particular case of the preceding lemma. \square

4.12. Remember from [Joy02] that a morphism of simplicial sets is called a *left* (resp. *right*) *fibration* if it has the right lifting property with respect to inclusions of shape $\Lambda^i[n] \longrightarrow \Delta[n]$ for $n \geq 1$ and $0 \leq i < n$ (resp. $0 < i \leq n$).

A morphism between ∞ -categories $X \longrightarrow Y$ is *conservative* if the induced functor $\tau(X) \longrightarrow \tau(Y)$ is conservative (which can be reformulated by saying that a 1-simplex of X is weakly invertible if and only if its image in Y is weakly invertible). For instance, by virtue of [Joy02, Proposition 2.7], any left (resp. right) fibration between ∞ -categories is conservative.

Proposition 4.13. *Let $p : X \longrightarrow Y$ be an inner Kan fibration of dendroidal sets under a forest \mathcal{T} . The map*

$$\mathcal{T} \setminus X \longrightarrow \mathcal{T} \setminus Y \times_{i^*(Y)} i^*(X)$$

is a left fibration.

In particular, for any ∞ -operad X under a forest \mathcal{T} , the map $\mathcal{T} \setminus X \longrightarrow i^(X)$ is a left fibration.*

Proof. This follows immediately from Proposition 4.11 by a standard adjunction argument. \square

Corollary 4.14. *For any ∞ -operad X and any forest \mathcal{T} over X , the simplicial set $\mathcal{T} \setminus X$ is an ∞ -category. Similarly, for any inner Kan fibration between ∞ -operads $X \longrightarrow Y$ and any forest \mathcal{T} over X , the simplicial set $\mathcal{T} \setminus Y \times_{i^*(Y)} i^*(X)$ is an ∞ -category.*

Proof. If X is an ∞ -operad, then $i^*(X)$ is clearly an ∞ -category. Since the projection $\mathcal{T} \setminus X \longrightarrow i^*(X)$ is a left fibration, this implies this corollary. \square

As a warm up to prove Theorem 4.2, we shall consider a particular case.

Lemma 4.15. *Theorem 4.2 is true if $T = () \star 1$ (where $()$ denotes the empty forest).*

Proof. In this case, T is a tree of shape

and $\Lambda^r[T]$ is the union of the two faces

In other words, we get $\Lambda^r[T] = (\) \star \Lambda^1[1] \cup \Omega[1]$. Thus, a lifting problem of shape

$$\begin{array}{ccc} \Lambda^r[T] & \xrightarrow{f} & X \\ \downarrow & \nearrow h & \downarrow p \\ \Omega[T] & \xrightarrow{g} & Y \end{array}$$

is equivalent to a lifting problem of shape

$$\begin{array}{ccc} \{1\} & \xrightarrow{\bar{f}} & (\) \setminus X \\ \downarrow & \nearrow \bar{h} & \downarrow \varphi \\ \Delta[1] & \xrightarrow{\bar{g}} & (\) \setminus Y \times_{i^*(Y)} i^*(X) \end{array}$$

By virtue of Proposition 4.13, the map φ is a left fibration, and, as left fibrations are stable by pullback and by composition, so is the projection of $(\) \setminus Y \times_{i^*(Y)} i^*(X)$ to $i^*(X)$. The image of \bar{g} by the latter is nothing but $f(r)$, and, as we know that left fibrations between ∞ -categories are conservative (see [Joy02, Proposition 2.7]), the 1-cell \bar{g} is quasi-invertible in $(\) \setminus Y \times_{i^*(Y)} i^*(X)$. We conclude the proof using [Joy02, Propositions 2.4 and 2.7]. \square

Proof of Theorem 4.2. Let T be a tree with at least two vertices and a unary vertex r at the root. There is a forest $\mathcal{T} = (T_1, \dots, T_k)$, $k \geq 0$, such that $T = \mathcal{T} \star 1$. By virtue of Lemma 4.15, we may assume that \mathcal{T} is not the empty forest, or, equivalently, that $k \geq 1$. We will write $T' = \mathcal{T} \star 0$. The trees T and T' can be represented as follows.

Given a dendroidal set X , a map $\Lambda^r[T] \rightarrow X$ corresponds to a compatible family of maps of simplicial sets

$$\{1\} = \Delta[0] \rightarrow \partial_A(T') \setminus X,$$

indexed by the *non-empty* admissible subset of edges A in T' . This family corresponds to a map

$$\Delta[0] \rightarrow \varprojlim_A \partial_A(T') \setminus X.$$

By separating the case $A = \{0\}$ (the root edge of T') from the others, the map $\Lambda^r[T] \rightarrow X$ corresponds to a commutative square of shape

$$\begin{array}{ccc} \Delta[0] & \longrightarrow & \mathcal{T} \setminus X \\ \partial_0 \downarrow & & \downarrow \\ \Delta[1] & \longrightarrow & \varprojlim \partial_{\bar{B}}(\mathcal{T}) \setminus X \end{array}$$

in which the limit $\varprojlim \partial_{\bar{B}}(\mathcal{T}) \setminus X$ is over the non-empty admissible subsets of edges B in \mathcal{T}' with $0 \notin B$, and $\bar{B} = (B \cap T_1, \dots, B \cap T_k)$.

Consider from now on an inner Kan fibration between ∞ -operads $p : X \rightarrow Y$. Lifting problems of shape

$$\begin{array}{ccc} \Lambda^r[T] & \xrightarrow{f} & X \\ \downarrow & \nearrow h & \downarrow p \\ \Omega[T] & \xrightarrow{g} & Y \end{array}$$

correspond to lifting problems

$$\begin{array}{ccc} \Delta[0] & \xrightarrow{\tilde{f}} & P \\ \partial_0 \downarrow & \nearrow \tilde{h} & \downarrow \varphi \\ \Delta[1] & \xrightarrow{\tilde{g}} & Q \end{array}$$

where $P = \mathcal{T} \setminus X$ and $Q = U \times_W V$, with

$$U = \varprojlim \partial_{\bar{B}}(\mathcal{T}) \setminus X, \quad V = \mathcal{T} \setminus Y, \quad W = \varprojlim \partial_{\bar{B}}(\mathcal{T}) \setminus Y.$$

Exactly like in the proof of Proposition 4.15, it now suffices to prove the following three statements:

- (i) the map $\varphi : P \rightarrow Q$ is a left fibration;
- (ii) the simplicial set Q is an ∞ -category;
- (iii) if $f(r)$ is weakly invertible in X , then the 1-cell \tilde{g} is weakly invertible in $i^*(Q)$.

Note that, as left fibrations are conservative and are stable by pullback and composition, statements (ii) and (iii) will follow from the following two assertions:

- (iv) the map $V \rightarrow W$ is a left fibration;
- (v) the map $U \rightarrow i^*(X)$ is a left fibration.

But (iv) is a particular case of (i): just replace p by the map from Y to the terminal dendroidal set. It thus remains to prove (i) and (v).

4.15.1. Proof of (i).

For $0 \leq i < n$, a lifting problem of the form

$$\begin{array}{ccc} \Lambda^i[n] & \longrightarrow & P \\ \downarrow & \nearrow & \downarrow \varphi \\ \Delta[n] & \longrightarrow & Q \end{array}$$

correspond to a lifting problem of the form

$$\begin{array}{ccc} \Lambda^i[\mathcal{T} \star n] & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow p \\ \Omega[\mathcal{T} \star n] & \longrightarrow & Y \end{array}$$

As $\Lambda^i[\mathcal{T} \star n]$ is an inner horn, (i) thus follows from the fact p is an inner Kan fibration.

4.15.2. Proof of (v).

For $0 \leq i < n$, a lifting problem of the form

$$\begin{array}{ccc} \Lambda^i[n] & \longrightarrow & U \\ \downarrow & \nearrow & \downarrow \\ \Delta[n] & \longrightarrow & i^*(X) \end{array}$$

corresponds to a lifting problem of the form

$$\begin{array}{ccc} C & \longrightarrow & X \\ \downarrow & \nearrow & \\ D & & \end{array}$$

where the inclusion $C \longrightarrow D$ can be described as follows. The dendroidal set D is the union of all the faces $\partial_x(\mathcal{T} \star n)$ given by contracting an inner edge or a root edge in one of the trees T_i , or by deleting a top vertex in the tree $\mathcal{T} \star n$. The dendroidal set C is the union of the image of $\Omega[n] \longrightarrow \Omega[\mathcal{T} \star n]$ and all the ‘codimension 2’ faces of $\Omega[\mathcal{T} \star n]$ of shape $\partial_j \partial_x(\mathcal{T} \star n)$, where ∂_x is as above, and $0 \leq j \leq n$ is distinct from i . It is now sufficient to check that the inclusion $C \longrightarrow D$ is an inner anodyne extension, which follows from a straightforward application of Lemma 4.10. \square

5. SUBDIVISION OF CYLINDERS

5.1. Let S be a tree with at least one vertex, and consider the tensor product $\Omega[S] \otimes \Delta[1]$. It has a subobject

$$A_0 = \partial\Omega[S] \otimes \Delta[1] \cup \Omega[S] \otimes \{1\}$$

where $\{1\} \longrightarrow \Delta[1]$ is $\partial_0 : \Delta[0] \longrightarrow \Delta[1]$. In this section, we will prove the following result.

Theorem 5.2. *There exists a filtration of $\Omega[S] \otimes \Delta[1]$ of the form*

$$A_0 \subset A_1 \subset \cdots \subset A_{N-1} \subset A_N = \Omega[S] \otimes \Delta[1],$$

where:

- (i) the inclusion $A_i \longrightarrow A_{i+1}$ is inner anodyne for $0 \leq i < N - 1$;
- (ii) the inclusion $A_{N-1} \longrightarrow A_N$ fits into a pushout of the form

$$\begin{array}{ccc} \Lambda^r[T] & \longrightarrow & A_{N-1} \\ \downarrow & & \downarrow \\ \Omega[T] & \longrightarrow & A_N \end{array}$$

for a tree T with at least two vertices and a unary vertex r at the root;

- (iii) the map

$$\Delta[1] \longrightarrow \Lambda^r[T] \longrightarrow A_{N-1} \subset \Omega[S] \otimes \Delta[1]$$

corresponding to the vertex r in (ii) coincides with the inclusion

$$\{e_S\} \otimes \Delta[1] \longrightarrow \Omega[S] \otimes \Delta[1]$$

where e_S is the edge at the root of the tree S .

5.3. The proof of Theorem 5.2 is in fact very similar to that of [MW09, Proposition 9.2], stated here as Proposition 3.1. We recall from *loc. cit.* that, for any two trees S and T , one can write

$$\Omega[S] \otimes \Omega[T] = \bigcup_{i=1}^N \Omega[T_i],$$

where $\Omega[T_i] \rightarrow \Omega[S] \otimes \Omega[T]$ are ‘percolation schemes’. Drawing vertices of S as white, and those of T as black, these percolation schemes are partially ordered in a natural way, starting with the tree obtained by stacking a copy of the black tree T on top of each input edge of the white tree S , and ending with the tree obtained by stacking copies of S on top of T . The intermediate trees are obtained by letting the black vertices of T percolate through the white tree S , by successive ‘moves’ of the form

In the special case where $T = [1]$, the filtration referred to in Theorem 5.2 is given by

$$A_i = A_0 \cup \Omega[T_1] \cup \cdots \cup \Omega[T_i],$$

where T_1, \dots, T_N is any linear order on the percolation schemes extending the natural partial order.

Remark 5.4. For any tree S with at least one vertex, and root edge named e_S (e for ‘exit’), the last tree T_N in the partial order of percolation schemes for $\Omega[S] \otimes \Delta[1]$ is of shape

It always has a unique predecessor T_{N-1} of the form

where S is of the form $(S_1, \dots, S_n) \star [0]$.

This observation already enables us to get

Proof of parts (ii) and (iii) of Theorem 5.2. Consider all the faces of T_N . For such a face $F \rightarrow T_N$, there are three possibilities;

- (a) it misses an S -colour entirely (i.e. there is an edge s in S so that neither $(s, 0)$ nor $(s, 1)$ are in F , so that $\Omega[F]$ factors through $\partial\Omega[S] \otimes \Delta[1]$;
- (b) F is given by contracting the edge $(e_S, 0)$, in which case $\Omega[F]$ factors through $\Omega[T_{N-1}]$ (since the face F then coincides with the face of T_{N-1} obtained by contracting $(s_1, 1), \dots, (s_n, 1)$);
- (c) F is given by chopping off the edge $(e_S, 1)$ and the black vertex above it, i.e. $\Omega[F] = \Omega[S] \otimes \{0\}$. This face cannot factor through A_0 , nor through any of the earlier percolation schemes since none of these has an edge coloured $(e_S, 0)$.

Thus, $\Omega[T_N] \cap A_{N-1} = \Lambda^r[T_N]$, where r denotes the black vertex as pictured above. This shows that

$$\begin{array}{ccc} \Lambda^r[T] & \longrightarrow & A_{N-1} \\ \downarrow & & \downarrow \\ \Omega[T] & \longrightarrow & A_N \end{array}$$

is a pushout, exactly as stated in part (ii) of Theorem 5.2. Moreover, the statement of part (iii) of Theorem 5.2 is obvious from the construction. \square

5.5. The proof of part (i) of Theorem 5.2 is more involved, but it is completely analogous to the proof of [MW09, Proposition 9.2]. The difference with the situation in *loc. cit.* is that, now, we are dealing with an inclusion of the form

$$\partial\Omega[S] \otimes \Omega[T] \cup \Omega[S] \otimes \Lambda^e[T] \longrightarrow \Omega[S] \otimes \Omega[T],$$

where e is an outer edge of $T = i[1]$, whereas in *loc. cit.*, we dealt with

$$\Omega[S] \otimes \partial\Omega[T] \cup \Lambda^e[S] \otimes \Omega[T] \longrightarrow \Omega[S] \otimes \Omega[T],$$

where e is an inner edge of S . This forces us to look at different ‘spines’ and ‘characteristic edges’ compared to the ones in *loc. cit.* (notice also in this connection that although the tensor product is symmetric, the partial order on the percolation schemes is reversed).

The following lemma was also used (implicitly) in [MW09].

Lemma 5.6. *Let T_i and T_j be two distinct percolation schemes for $\Omega[S] \otimes \Delta[1]$. Then*

$$\Omega[T_i] \cap \Omega[T_j] \subset \cup_k \Omega[T_k]$$

as subobjects of $\Omega[S] \otimes \Delta[1]$, where the union ranges over all the percolation schemes T_k which precede both T_i and T_j in the partial order.

Proof. Let F be a common face of $\Omega[T_i]$ and $\Omega[T_j]$. If $T_j \leq T_i$ in the partial order, there is nothing to prove. Otherwise, we will give an algorithm for replacing T_j by successively earlier percolation schemes,

$$T_j = T_{j_0} \geq T_{j_1} \geq T_{j_2} \geq \dots$$

each having F as a face, and eventually preceding T_i in the partial order. As a first step, T_j is obtained from an earlier percolation scheme $T_{j'}$ by changing

If F is also a face of $T_{j'}$, we ‘push up the black vertices’ by replacing T_j by $T_{j_1} = T_{j'}$. If not, then the colour $(s,0)$ must occur in F , hence in T_j as well as in T_i . So the occurrence of $(s,0)$ in T_j is not the reason that $T_j \not\leq T_i$, and we put $T_{j_1} = T_j$. Treating all black vertices in this way, we can push them up if they occur below black vertices in T_i , until we eventually reach a percolation scheme $T_{j_n} \leq T_j$, still having F as a face, for which $T_{j_n} \leq T_i$. \square

5.7. We return to the proof of Theorem 5.2. Consider the inclusion

$$(5.7.1) \quad A_k \longrightarrow A_{k+1} = A_k \cup \Omega[T_{k+1}],$$

for $k+1 < N$. The percolation scheme T_{k+1} will have at least one black vertex. Consider all the black vertices in T_{k+1} , and the corresponding faces of T_{k+1} which are formed by paths from these black vertices to the root of T_{k+1} :

The face β is the minimal external face which contains the given black vertex as well as the root edge. We call a face β of T_{k+1} of this form a *spine* in T_{k+1} . Notice that the vertex just above $(e_S, 1)$ is indeed white, as in the picture, because $k+1 < N$. Notice also that the outer face of β given by chopping off this vertex misses the colour e_S , hence belongs to $\partial\Omega[S] \otimes \Delta[1] \subset A_0$. Furthermore, the outer face of β given by chopping off its black top vertex belongs to $\Omega[S] \otimes \{1\} \subset A_0$. Finally, all the inner faces of β miss an S -colour, hence factor through $\partial\Omega[S] \otimes \Delta[1]$, except possibly the one given by contracting the edge $(s, 1)$ near the top. However, if this last face $\partial_{(s,1)}(\beta)$ of β belongs to A_k , then some earlier T_i , $1 \leq i \leq k$, contains the edge $(s, 0)$, hence all of β . Thus, either $\Omega[\beta]$ is contained in A_k , or we can adjoin it

by an inner anodyne extension

$$(5.7.3) \quad \begin{array}{ccc} \Lambda^{(s,1)}[\beta] & \longrightarrow & A_k \\ \downarrow & & \downarrow \\ \Omega[\beta] & \longrightarrow & A_k \cup \Omega[\beta]. \end{array}$$

Such a spine β is an example of an *initial segment* of T_{k+1} . Recall from [MW09] that a face $R \rightarrow T_{k+1}$ is called an *initial segment* if it is obtained by successively chopping off top vertices. Our strategy will be to adjoin more initial segments of T_{k+1} to A_k , starting with the spines. To this end, we need the following definition and lemma from [MW09], in which we use the notation $m(R) \subset \Omega[T_{k+1}]$ for the image of the map $\Omega[R] \rightarrow \Omega[T_{k+1}]$ given by an initial segment R .

Definition 5.8 ([MW09]). Let R, Q_1, \dots, Q_p be initial segments of T_{k+1} , and let $B = m(Q_1) \cup \dots \cup m(Q_p)$. Suppose that, for every top face F of R , we have $m(F) \subset A_k \cup B$. In this situation, an inner edge ξ of R is called *characteristic* with respect to Q_1, \dots, Q_p if, for any inner face F of R , if $m(F/\xi)$ is contained in $A_k \cup B$, then so is $m(F)$ (where $F/\xi \rightarrow F$ is the face obtained by contracting ξ).

Example 5.9. In any spine β as in picture (5.7.2), the edge $\xi = (s, 1)$ is characteristic with respect to any family of initial segments.

Example 5.10. More generally, suppose R is an initial segment of T_{k+1} given by a spine β expanded by one (or more) white vertices, say

Then $\xi = (s, 1)$ is again characteristic with respect to any family Q_1, \dots, Q_p . Indeed, if R/ξ is a face of an initial segment Q_i , then so is R itself; see [MW09, Remark 9.6 (iv)]. And if R/ξ is a face of T_j for a percolation scheme T_j , then T_j either contains R , or looks like

But, by Lemma 5.6, we can assume T_j comes before T_{k+1} in the partial order, so this is impossible. Finally, if $\Omega[R/\xi] \rightarrow \Omega[S] \otimes \Delta[1]$ factors through A_0 , then R/ξ misses an S -colour, and hence so does R .

5.11. The proof of Theorem 5.2 (i) is based on a repeated use of arguments like the preceding one in Example 5.10. We quote the following lemma on characteristic edges from [MW09].

Lemma 5.12 ([MW09, Lemma 9.7]). *Let R, Q_1, \dots, Q_p be initial segments of T_{k+1} . Let $B = m(Q_1) \cup \dots \cup m(Q_p)$, and suppose each top face of R has the property that $m(F)$ is contained in $A_k \cup B$. If R possesses a characteristic edge with respect to Q_1, \dots, Q_p , then the inclusion*

$$A_k \cup B \longrightarrow A_k \cup B \cup m(R)$$

of subobjects of $\Omega[S] \otimes \Delta[1]$ is inner anodyne.

Lemma 5.13. *Let R, Q_1, \dots, Q_p be initial segments of T_{k+1} , satisfying condition (i) in Definition 5.8, and let β be a spine in R . Then the edge $\xi = (s, 1)$ immediately below the black vertex on the spine is a characteristic edge for R .*

Hint for a proof. This is proved exactly as Example 5.10; cf. also [MW09, Lemma 9.8]. \square

5.14. Using the characteristic edges from Lemma 5.13, one can now copy the proof of [MW09, Lemma 9.9], repeated below as Lemma 5.15, verbatim. This proof is by induction on l , and describes a precise strategy for adjoining more and/or larger initial segments of T_{k+1} to A_k .

Lemma 5.15. *Fix $l \leq 0$, and let Q_1, \dots, Q_p be a family of initial segments in T_{k+1} , each containing at least one spine, and at most l spines (so, necessarily, $p = 0$ if $l = 0$). Let R_1, \dots, R_q be initial segments which each contain exactly $l + 1$ spines. Then the inclusion $A_k \longrightarrow A_k \cup B \cup C$ is inner anodyne, where $B = m(Q_1) \cup \dots \cup m(Q_p)$ and $C = m(R_1) \cup \dots \cup m(R_q)$.*

5.16. This strategy terminates when one arrives at the number l of all spines in T_{k+1} . Indeed, for this l and $p = 0, q = 1$, Lemma 5.15 states for $R_1 = T_{k+1}$ that $A_k \longrightarrow A_{k+1}$ is inner anodyne, as asserted in Theorem 5.2 (i). This completes the proof of Theorem 5.2.

6. ∞ -OPERADS AS FIBRANT OBJECTS

6.1. The aim of this section is to characterize ∞ -operads as the fibrant objects of the model category structure on the the category of dendroidal sets given by Proposition 3.12. This characterization is stated in Theorem 6.10 below.

Given an ∞ -category X , we denote by $k(X)$ the maximal Kan complex contained in X ; see [Joy02, Corollary 1.5].

Recall that, given two dendroidal sets A and X , we write

$$\mathit{hom}(A, X) = i^* \mathcal{H}om(A, X).$$

Note that, by virtue of Proposition 3.1, if X is an ∞ -operad, and if A is normal, then $\mathcal{H}om(A, X)$ is an ∞ -operad, so that $\mathit{hom}(A, X)$ is an ∞ -category.

For an ∞ -operad X and a simplicial set K , we will write $X^{(K)}$ for the subcomplex of $\mathcal{H}om(i_l(K), X)$ which consists of dendrices

$$a : \Omega[T] \times i_l(K) \longrightarrow X$$

such that, for any 0-cell u in T , the induced map

$$a_u : K \longrightarrow i^*(X)$$

factors through $k(i^*(X))$ (i.e. all the 1-cells in the image of a_u are weakly invertible in $i^*(X)$).

For an ∞ -operad X and a normal dendroidal set A , we will write $k(A, X)$ for the subcomplex of $\mathit{hom}(A, X)$ which consists of maps

$$u : A \otimes i_!(\Delta[n]) \longrightarrow X$$

such that, for all vertices a of A (i.e. maps $a : \eta \longrightarrow A$), the induced map

$$u_a : \Delta[n] \longrightarrow i^*(X)$$

factors through $k(i^*(X))$. So, by definition, for any normal dendroidal set A , any simplicial set K , and any ∞ -operad X , there is a natural bijection:

$$(6.1.1) \quad \mathrm{Hom}_{\mathit{sSet}}(K, k(A, X)) \simeq \mathrm{Hom}_{\mathit{dSet}}(A, X^{(K)}).$$

Remark 6.2. The simplicial set $k(A, X)$ is by definition the ∞ -category of objectwise weakly invertible 1-cells in $\mathit{hom}(A, X)$. We can reformulate the definition of $k(A, X)$ as follows (still with A normal and X an ∞ -operad). Define

$$(6.2.1) \quad \mathrm{Ob} A = \prod_{A_0} \eta.$$

We have a unique monomorphism $i : \mathrm{Ob} A \longrightarrow A$ which is the identity on 0-cells. As A is normal, i is a normal monomorphism. We also have

$$(6.2.2) \quad k(\mathrm{Ob} A, X) = k(\mathit{hom}(\mathrm{Ob} A, X)) = \prod_{A_0} k(i^* X),$$

and $k(A, X)$ fits by definition in the following pullback square.

$$(6.2.3) \quad \begin{array}{ccc} k(A, X) & \longrightarrow & \mathit{hom}(A, X) \\ \downarrow & & \downarrow \\ k(\mathit{hom}(\mathrm{Ob} A, X)) & \longrightarrow & \mathit{hom}(\mathrm{Ob} A, X) \end{array}$$

In particular, the projection of $k(A, X)$ on $k(\mathrm{Ob} A, X)$ is an inner Kan fibration, and as the latter is a Kan complex, this shows that $k(A, X)$ is an ∞ -category. One of the key results of this section asserts that $k(A, X)$ is a Kan complex as well, which can be reformulated by saying that the inclusion $k(\mathit{hom}(A, X)) \subset k(A, X)$ is in fact an equality. In other words, a map in the ∞ -category $\mathit{hom}(A, X)$ is weakly invertible if and only if it is objectwise weakly invertible; see Corollary 6.8.

6.3. Before stating the next theorem, we recall that, for a morphism between ∞ -categories $f : X \longrightarrow Y$, the induced map $\tau(f) : \tau(X) \longrightarrow \tau(Y)$ is a categorical fibration if and only if the map

$$ev_1 : X^{(\Delta[1])} \longrightarrow Y^{(\Delta[1])} \times_Y X$$

induced by evaluating at 1 (i.e. by the inclusion $\{1\} \longrightarrow \Delta[1]$) has the right lifting property with respect to $\partial\Delta[0] \longrightarrow \Delta[0]$; see [Joy02, Proposition 2.4].

Theorem 6.4. *Let $p : X \longrightarrow Y$ be an inner Kan fibration between ∞ -operads. The map $ev_1 : X^{(\Delta[1])} \longrightarrow Y^{(\Delta[1])} \times_Y X$ has the right lifting property with respect to inclusions $\partial\Omega[S] \longrightarrow \Omega[S]$ for any tree S with at least one vertex. Consequently, the functor $\tau i^*(p)$ is a categorical fibration if and only if the evaluation at 1 map $X^{(\Delta[1])} \longrightarrow Y^{(\Delta[1])} \times_Y X$ is a trivial fibration of dendroidal sets.*

Proof. Consider a tree S with at least one vertex and a solid commutative square

$$\begin{array}{ccc} \partial\Omega[S] & \xrightarrow{f} & X^{(\Delta[1])} \\ \downarrow & \nearrow h & \downarrow \\ \Omega[S] & \xrightarrow{g} & Y^{(\Delta[1])} \times_Y X \end{array}$$

We want to prove the existence of a diagonal filling h . This corresponds by adjunction to a filling \tilde{h} in the following commutative square

$$\begin{array}{ccc} \partial\Omega[S] \otimes \Delta[1] \cup \Omega[S] \otimes \{1\} & \xrightarrow{\tilde{f}} & X \\ \downarrow & \nearrow \tilde{h} & \downarrow \\ \Omega[S] \otimes \Delta[1] & \xrightarrow{\tilde{g}} & Y \end{array}$$

(as the inclusion of $\partial\Omega[S]$ in $\Omega[S]$ is bijective on objects, and as the restriction of \tilde{h} to $\partial\Omega[S] \otimes \Delta[1] \cup \Omega[S] \otimes \{1\}$ coincides with \tilde{f} , the map $\Omega[S] \rightarrow X^{\Delta[1]}$ corresponding to a filling \tilde{h} will automatically factor through $X^{(\Delta[1])}$).

Consider the filtration

$$\partial\Omega[S] \otimes \Delta[1] \cup \Omega[S] \otimes \{1\} = A_0 \subset A_1 \subset \cdots \subset A_{N-1} \subset A_N = \Omega[S] \otimes \Delta[1]$$

given by Theorem 5.2. As the map $X \rightarrow Y$ is an inner Kan fibration, using Theorem 5.2 (i), it is sufficient to find a filling in a solid commutative diagram of shape

$$\begin{array}{ccc} A_{N-1} & \xrightarrow{f'} & X \\ \downarrow & \nearrow \tilde{h} & \downarrow \\ \Omega[S] \otimes \Delta[1] & \xrightarrow{\tilde{g}} & Y \end{array}$$

in which the restriction of f' to $\partial\Omega[S] \otimes \Delta[1] \cup \Omega[S] \otimes \{1\}$ coincides with \tilde{f} . By virtue of Theorem 5.2 (ii), it is even sufficient to find a filling k in a solid commutative diagram of shape

$$\begin{array}{ccc} \Lambda^r[T] & \xrightarrow{a} & X \\ \downarrow & \nearrow k & \downarrow \\ \Omega[T] & \xrightarrow{b} & Y \end{array}$$

in which T is a tree with unary vertex r at the root, and a is the restriction of f' to $\Lambda^r[T] \subset A_{N-1}$. Furthermore, by Theorem 5.2 (iii), we may assume that $a(r)$ is weakly invertible in $i^*(X)$. Thus, the existence of the filling k is ensured by Theorem 4.2.

The last assertion of the theorem follows from 6.3. \square

Lemma 6.5. *Any left fibration between Kan complexes is a Kan fibration.*

Proof. This follows from [Joy02, Theorem 2.2 and Proposition 2.7]. \square

Lemma 6.6. *A morphism of simplicial sets $X \rightarrow Y$ is a left (resp. right) fibration if and only if it has the right lifting property with respect to maps of shape*

$$\partial\Delta[n] \times \Delta[1] \cup \Delta[n] \times \{e\} \rightarrow \Delta[n] \times \Delta[1]$$

for $e = 1$ (resp. for $e = 0$) and $n \geq 0$.

Proof. The map $\partial\Delta[n] \times \Delta[1] \cup \Delta[n] \times \{0\} \longrightarrow \Delta[n] \times \Delta[1]$ is obtained as a finite composition of pushouts of horns of shape $\Lambda^k[n+1] \longrightarrow \Delta[n+1]$ with $0 \leq k < n+1$; see (the dual version of) [GZ67, Chapter IV, 2.1.1].

Conversely, the inclusion map $\Lambda^k[n] \longrightarrow \Delta[n]$, $0 \leq k < n$, is a retract of the map $\Lambda^k[n] \times \Delta[1] \cup \Delta[n] \times \{0\} \longrightarrow \Delta[n] \times \Delta[1]$; see [GZ67, Chapter IV, 2.1.3].

We deduce easily from this that a morphism of simplicial sets $X \longrightarrow Y$ is a right fibration if and only if the evaluation at 0 map $X^{\Delta[1]} \longrightarrow Y^{\Delta[1]} \times_Y X$ is a trivial fibration (i.e. has the right lifting property with respect to monomorphisms). The case of left fibrations follows by duality. \square

Proposition 6.7. *Let $p : X \longrightarrow Y$ be an inner Kan fibration between ∞ -operads. If $\tau i^*(p)$ is a categorical fibration, then, for any monomorphism between normal dendroidal sets $A \longrightarrow B$, the map*

$$k(B, X) \longrightarrow k(B, Y) \times_{k(A, Y)} k(A, X)$$

is a Kan fibration between Kan complexes.

Proof. The functor $i_! : sSet \longrightarrow dSet$ being symmetric monoidal and preserving inner anodyne extensions, Proposition 3.1 implies that the map

$$hom(B, X) \longrightarrow hom(B, Y) \times_{hom(A, Y)} hom(A, X)$$

is an inner Kan fibration between ∞ -categories. This implies the map

$$k(B, X) \longrightarrow k(B, Y) \times_{k(A, Y)} k(A, X)$$

is an inner Kan fibration between ∞ -categories.

We claim that this map has the right lifting property with respect to the inclusion $\{1\} \longrightarrow \Delta[1]$. Using the identification (6.1.1), we see that lifting problems of shape

$$(6.7.1) \quad \begin{array}{ccc} \{1\} & \longrightarrow & k(B, X) \\ \downarrow & \nearrow \text{dotted} & \downarrow \\ \Delta[1] & \longrightarrow & k(B, Y) \times_{k(A, Y)} k(A, X) \end{array}$$

correspond to lifting problems of shape

$$(6.7.2) \quad \begin{array}{ccc} A & \longrightarrow & X^{(\Delta[1])} \\ \downarrow & \nearrow \text{dotted} & \downarrow \\ B & \longrightarrow & Y^{(\Delta[1])} \times_Y X \end{array}$$

so that our claim follows from Theorem 6.4.

More generally, the map $k(B, X) \longrightarrow k(B, Y) \times_{k(A, Y)} k(A, X)$ has the right lifting property with respect to maps of shape

$$(6.7.3) \quad \partial\Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} \longrightarrow \Delta[n] \times \Delta[1], \quad n \geq 0.$$

We have just checked it above in the case where $n = 0$, so that it remains to prove the case where $n > 0$. Consider a lifting problem of shape

$$(6.7.4) \quad \begin{array}{ccc} \partial\Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} & \xrightarrow{u} & k(B, X) \\ \downarrow & \nearrow g & \downarrow \\ \Delta[n] \times \Delta[1] & \xrightarrow{v} & k(B, Y) \times_{k(A, Y)} k(A, X) \end{array}$$

This lifting problem gives rise to a lifting problem of shape

$$(6.7.5) \quad \begin{array}{ccc} \partial\Omega[n] \otimes B \cup \Omega[n] \otimes A & \xrightarrow{\quad} & X^{(\Delta[1])} \\ \downarrow & \nearrow h & \downarrow \\ \Omega[n] \otimes B & \xrightarrow{\quad} & Y^{(\Delta[1])} \times_Y X. \end{array}$$

The existence of the lifting h is provided again by Theorem 6.4. The map h defines a map

$$l : i_!(\Delta[n] \times \Delta[1]) \otimes B \longrightarrow X.$$

As a consequence, it is sufficient to check that, for every non-degenerate m -simplex $\delta : \Delta[m] \longrightarrow \Delta[n] \times \Delta[1]$, $m \geq 1$, and for any object $b : \eta \longrightarrow B$, the map $(li_!(\delta))_b : \Delta[m] \longrightarrow i^*(X)$ factors through $k(i^*(X))$. Using the ‘2 out of 3 property’ for weakly invertible 1-cells in $i^*(X)$, we can assume that $m = 1$. But then, as $n > 0$, using again the ‘2 out of 3 property’ for weakly invertible 1-cells, we may assume that δ factors through $\partial\Delta[n] \times \Delta[1]$, which implies then that $(l \circ i_!(\delta)) \otimes 1_B$ factors through the subcomplex $i_!(\partial\Delta[n] \times \Delta[1]) \otimes B$: the required property thus follows from the fact that the restriction of the transpose of h to the object $i_!(\Delta[n] \times \Delta[1] \cup \partial\Delta[n] \times \{1\}) \otimes B$ corresponds to the map u in (6.7.4).

By virtue of Lemma 6.6, the map $k(B, X) \longrightarrow k(B, Y) \times_{k(A, Y)} k(A, X)$ is a left fibration, hence, by [Joy02, Proposition 2.7], is conservative. By applying [Joy02, Corollary 1.4], we deduce, from the case where $A = \emptyset$ and Y is the terminal dendroidal set, that $k(B, X)$ is a Kan complex for any normal dendroidal set B and any ∞ -operad X . As any left fibration between Kan complexes is a Kan fibration (Lemma 6.5), the maps $k(B, X) \longrightarrow k(A, X)$ are thus Kan fibrations between Kan complexes for any monomorphisms between normal dendroidal sets $A \longrightarrow B$ and any ∞ -operad X . As a consequence, Kan fibrations being stable by pullback, we see that the fiber product $k(B, Y) \times_{k(A, Y)} k(A, X)$ is a Kan complex. Using again Lemma 6.5, we conclude that $k(B, X) \longrightarrow k(B, Y) \times_{k(A, Y)} k(A, X)$ is a Kan fibration between Kan complexes. \square

Corollary 6.8. *For any normal dendroidal set A and any ∞ -operad X , we have*

$$k(\mathfrak{hom}(A, X)) = k(A, X).$$

For any inner Kan fibration between ∞ -operads $p : X \longrightarrow Y$ such that $\tau i^(p)$ is a categorical fibration, and for any monomorphism between normal dendroidal sets $A \longrightarrow B$, we have*

$$k(\mathfrak{hom}(B, Y) \times_{\mathfrak{hom}(A, Y)} \mathfrak{hom}(A, X)) = k(B, Y) \times_{k(A, Y)} k(A, X).$$

Proof. If A is normal, then, for any operad X , $k(A, X)$ is a Kan complex which contains $k(\mathit{hom}(A, X))$. As $k(\mathit{hom}(A, X))$ is the maximal sub Kan complex contained in the ∞ -category $\mathit{hom}(A, X)$, this proves the first assertion. The second assertion is proved similarly. \square

Corollary 6.9. *Let $p : X \rightarrow Y$ be an inner Kan fibration between ∞ -operads. If $\tau i^*(p)$ is a categorical fibration, then, for any anodyne extension of simplicial sets $K \rightarrow L$, the map*

$$X^{(L)} \rightarrow Y^{(L)} \times_{Y^{(K)}} X^{(K)}$$

is a trivial fibration of dendroidal sets.

Proof. This follows from Proposition 6.7 and from the natural identification (6.1.1). \square

Theorem 6.10. *A dendroidal set is J -fibrant if and only if it is an ∞ -operad. An inner Kan fibration between ∞ -operads $p : X \rightarrow Y$ is a J -fibration (i.e. a fibration for the model category structure of Proposition 3.12) if and only if $\tau i^*(p)$ is a categorical fibration.*

Proof. Let $p : X \rightarrow Y$ be inner Kan fibration between ∞ -operads. We have to prove that, for $e = 0, 1$, the anodyne extension $\{e\} \rightarrow J$ induces a trivial fibration of dendroidal sets

$$X^{J_e} \rightarrow Y^{J_e} \times_Y X$$

if and only if $\tau i^*(p)$ is a categorical fibration. But, for any ∞ -operad Z , we clearly have $Z^{J_e} = Z^{(J)}$ and $Z = Z^{\{e\}}$. Hence, by virtue of Corollary 6.9, if $\tau i^*(p)$ is a categorical fibration, then p is a J -fibration. The converse is a direct consequence of [Joy02, Corollary 1.6]. \square

Corollary 6.11. *The class of weak operadic equivalences is the smallest class of maps of dendroidal sets \mathcal{W} which satisfies the following three properties.*

- (a) (“2 out 3 property”) *In any commutative triangle, if two maps are in \mathcal{W} , then so is the third.*
- (b) *Any inner anodyne extension is in \mathcal{W} .*
- (c) *Any trivial fibration between ∞ -operads is in \mathcal{W} .*

Proof. Consider a class of maps \mathcal{W} satisfying conditions (a), (b) and (c) above. We want to prove that any weak operadic equivalence is in \mathcal{W} .

Let $f : A \rightarrow B$ be a morphism of dendroidal sets. Using the small object argument applied to the set of inner horns, we can see there exists a commutative square

$$\begin{array}{ccc} A & \xrightarrow{a} & X \\ f \downarrow & & \downarrow p \\ B & \xrightarrow{b} & Y \end{array}$$

in which the maps a and b are inner anodyne extensions, and X and Y are ∞ -operads. It is clear that f is a weak operadic equivalence (resp. is in \mathcal{W}) if and only if p has the same property. Hence it is sufficient to prove that any weak operadic equivalence between ∞ -operads is in \mathcal{W} . As any trivial fibration between ∞ -operads is in \mathcal{W} by assumption, and as ∞ -operads are the fibrant objects of a model category, this corollary follows from Ken Brown’s Lemma [Hov99, Lemma 1.1.12]. \square

6.12. We will write C_n for the corolla with $n + 1$ edges,

$$C_n = \begin{array}{c} \text{.....} \\ \diagup \quad | \quad \diagdown \\ a_1 \quad a_2 \quad a_n \\ \bullet \\ a \end{array} .$$

Let X be an ∞ -operad. Given an $(n + 1)$ -tuple of 0-cells (x_1, \dots, x_n, x) in X , the space of maps $X(x_1, \dots, x_n; x)$ is obtained by the pullback below, in which the map p is the map induced by the inclusion $\eta \amalg \dots \amalg \eta \longrightarrow \Omega[C_n]$ (with $n + 1$ copies of η , corresponding to the $n + 1$ objects (a_1, \dots, a_n, a) of C_n).

$$\begin{array}{ccc} X(x_1, \dots, x_n; x) & \longrightarrow & \mathcal{H}om(\Omega[C_n], X) \\ \downarrow & & \downarrow p \\ \eta & \xrightarrow{(x_1, \dots, x_n, x)} & X^{n+1} \end{array}$$

Using the identification $sSet = dSet/\eta$, we shall consider $X(x_1, \dots, x_n; x)$ as a simplicial set.

Proposition 6.13. *The simplicial set $X(x_1, \dots, x_n; x)$ is a Kan complex.*

Proof. The first assertion of Corollary 6.8 for $A = \Omega[C_n]$ can be reinterpreted by saying we have the pullback square below (see Remark 6.2).

$$\begin{array}{ccc} k(\mathit{hom}(\Omega[C_n], X)) & \longrightarrow & \mathcal{H}om(\Omega[C_n], X) \\ \downarrow & & \downarrow \\ k(i^* X)^{n+1} & \longrightarrow & X^{n+1} \end{array}$$

As the terminal simplicial set η is certainly a Kan complex, it thus follows from the construction of $X(x_1, \dots, x_n; x)$ that we have a pullback square

$$\begin{array}{ccc} X(x_1, \dots, x_n; x) & \longrightarrow & k(\mathit{hom}(\Omega[C_n], X)) \\ \downarrow & & \downarrow \\ \eta & \xrightarrow{(x_1, \dots, x_n, x)} & k(i^* X)^{n+1} \end{array}$$

in which the right vertical map in this diagram is a Kan fibration (by Proposition 6.7, applied for $A = \eta \amalg \dots \amalg \eta$ and $B = \Omega[C_n]$). The stability of Kan fibrations by pullback achieves the proof. \square

Proposition 6.14. *There is a canonical bijection*

$$\pi_0(X(x_1, \dots, x_n; x)) \simeq \tau_d(X)(x_1, \dots, x_n; x).$$

Proof. We will use the explicit description of $\tau_d(X)$ given by [MW09, Lemma 6.4 and Proposition 6.6]. The unit map $X \longrightarrow N_d\tau_d(X)$ induces a map

$$X(x_1, \dots, x_n; x) \longrightarrow (N_d\tau_d(X))(x_1, \dots, x_n; x).$$

It is easily seen that $(N_d\tau_d(X))(x_1, \dots, x_n; x)$ is the discrete simplicial set associated to $\tau_d(X)(x_1, \dots, x_n; x)$, so that we get a surjective map

$$\pi_0(X(x_1, \dots, x_n; x)) \longrightarrow \tau_d(X)(x_1, \dots, x_n; x).$$

Using the explicit description of $\tau_d(X)$ given by [MW09, Lemma 6.4 and Proposition 6.6], it is now sufficient to prove that, if f and g are two 0-simplices of $X(x_1, \dots, x_n; x)$ which are homotopic along the edge 0 in the sense of [MW09, Definition 6.2], then they belong to the same connected component. But then, f and g define two objects of $\tau(\mathit{hom}(\Omega[C_n], X))$ which are isomorphic, which can be expressed by the existence of a map

$$h : \Delta[1] \longrightarrow k(\mathit{hom}(\Omega[C_n], X))$$

which connect f and g . Using that $k(\mathit{hom}(\Omega[C_n], X)) \longrightarrow i^*(X)^{n+1}$ is a Kan fibration between Kan complexes, we can see by a path lifting argument that such a map h is homotopic under $\partial\Delta[1]$ to a map $\Delta[1] \longrightarrow X(x_1, \dots, x_n; x)$ which connects f and g . \square

Lemma 6.15. *Let $X \longrightarrow Y$ be a trivial fibration between ∞ -operads. Then, for any $(n+1)$ -tuple of 0-cells (x_1, \dots, x_n, x) in X , the induced map*

$$X(x_1, \dots, x_n; x) \longrightarrow Y(f(x_1), \dots, f(x_n); f(x))$$

is a trivial fibration of simplicial sets.

Proof. We know that the map

$$\mathcal{H}om(\Omega[C_n], X) \longrightarrow \mathcal{H}om(\Omega[C_n], Y) \times_{Y^{n+1}} X^{n+1}$$

is a trivial fibration (this follows from Proposition 1.9 by adjunction). As we have a pullback of shape

$$\begin{array}{ccc} X(x_1, \dots, x_n; x) & \longrightarrow & \mathcal{H}om(\Omega[C_n], X) \\ \downarrow & & \downarrow \\ Y(f(x_1), \dots, f(x_n); f(x)) & \longrightarrow & \mathcal{H}om(\Omega[C_n], Y) \times_{Y^{n+1}} X^{n+1} \end{array}$$

this proves the lemma. \square

Proposition 6.16. *The functor $\tau_d : \mathit{dSet} \longrightarrow \mathit{Operad}$ sends weak operadic equivalences to equivalences of operads.*

Proof. We know that τ_d sends inner horn inclusions to isomorphisms of operads (this follows from [MW09, Theorem 6.1] by the Yoneda Lemma). As τ_d preserves colimits, we deduce that τ_d sends inner anodyne extensions to isomorphisms of operads. By virtue of Corollary 6.11, it is thus sufficient to prove that τ_d sends trivial fibrations between ∞ -operads to equivalences of operads. Let $f : X \longrightarrow Y$ be a trivial fibration between ∞ -operads. By virtue of Proposition 6.14 and of Lemma 6.15, we see that $\tau_d(f)$ is fully faithful. As f is obviously surjective on 0-cells, $\tau_d(f)$ has to be an equivalence of operads. \square

Corollary 6.17. *The adjunction $\tau_d : \mathit{dSet} \rightleftarrows \mathit{Operad} : N_d$ is a Quillen pair. Moreover, the two functors τ_d and N_d both preserve weak equivalences. In particular, a morphism of operads is an equivalence of operads if and only if its dendroidal nerve is a weak operadic equivalence.*

Given an integer $n \geq 0$, we define the tree $n \star_e T$ as the tree obtained by joining the n -simplex to the edge e by a new vertex v .

$$(A.1.2) \quad n \star_e T = \begin{array}{c} \begin{array}{c} 0 \\ \bullet \\ 1 \\ | \\ \vdots \\ \bullet \\ n \\ \bullet \\ v \\ | \\ e \\ \bullet \\ \vdots \\ \bullet \end{array} \\ \dashrightarrow \\ \bullet \end{array}$$

This defines a unique functor

$$(A.1.3) \quad \Delta \longrightarrow \Omega, \quad [n] \longmapsto n \star_e T$$

such that the obvious inclusions $i[n] \longrightarrow n \star_e T$ are functorial. We thus get a functor

$$(A.1.4) \quad (-) \star_e T : \Delta \longrightarrow T/dSet$$

(where $T/dSet$ denotes the category of dendroidal sets under $\Omega[T]$). By Kan extension, we obtain a colimit preserving functor

$$(A.1.5) \quad (-) \star_e T : sSet \longrightarrow T/dSet.$$

We have $\Delta[n] \star_e T = \Omega[n \star_e T]$. The functor (A.1.5) has a right adjoint

$$(A.1.6) \quad (-)/_e T : T/dSet \longrightarrow sSet.$$

Remark A.2 (Functoriality in T). We shall say that a face map $R \longrightarrow T$ is *e-admissible* if it does not factor through the external face map which chops off e . For such a face $R \longrightarrow T$, e is also a leaf of R , and there are natural maps

$$(A.2.1) \quad n \star_e R \longrightarrow n \star_e T.$$

Thus, we obtain, for each simplicial set K , and each dendroidal set X under T (i.e. under $\Omega[T]$), natural maps

$$(A.2.2) \quad K \star_e R \longrightarrow K \star_e T$$

and

$$(A.2.3) \quad X/_e T \longrightarrow X/_e R.$$

Similarly, the inclusions $\Omega[n] \longrightarrow \Delta[n] \star_e T$ induce a projection

$$(A.2.4) \quad X/_e T \longrightarrow i^*(X)$$

for any dendroidal set X under T .

A.3. Let $0 < i \leq n$ be integers. Let $\{R_1, \dots, R_t\}$, $t \geq 1$, be a finite family of *e*-admissible faces of T , and define

$$C \subset D \subset \Omega[n \star_e T]$$

by

$$C = \left(\bigcup_{s=1}^t \Lambda^i [n] \star_e R_s \right) \cup \Omega[n] \quad \text{and} \quad D = \bigcup_{s=1}^t \Delta[n] \star_e R_s,$$

where $\Omega[n]$ is seen as a subcomplex of $\Omega[n \star_e T]$ through the canonical embedding.

Lemma A.4. *Under the assumptions of A.3, the map $C \rightarrow D$ is an inner anodyne extension.*

Proof. For $p \geq 1$, write \mathcal{F}_p for the set of faces F of $\Omega[n \star_e T]$ which belong to D but not to C , and which are of the form $F = \Omega[n \star_e R]$ for an e -admissible face R of T with exactly p edges. Define a filtration

$$C = C_0 \subset C_1 \subset \dots \subset C_p \subset \dots \subset D$$

by

$$C_p = C_{p-1} \cup \bigcup_{F \in \mathcal{F}_p} F, \quad p \geq 1.$$

We have $D = C_p$ for p big enough, and it is sufficient to prove that the inclusions $C_{p-1} \rightarrow C_p$ are inner anodyne for $p \geq 1$. If F and F' are in \mathcal{F}_p , then $F \cap F'$ is in C_{p-1} . Moreover, if $F = \Omega[n \star_e R]$ for an e -admissible face R of T , then we have

$$F \cap C_{p-1} = \Lambda^i[n \star_e R],$$

which is an inner horn. Hence we can describe the inclusion $C_{p-1} \rightarrow C_p$ as a finite composition of pushouts by inner horn inclusions of shape $F \cap C_{p-1} \rightarrow F$ for $F \in \mathcal{F}_p$. \square

Proposition A.5. *Let $0 < i \leq n$ be integers. The inclusion*

$$(\Lambda^i[n] \star_e T) \cup \Omega[n] \rightarrow \Omega[n \star_e T]$$

is an inner anodyne extension.

Proof. Apply Lemma A.4. \square

Proposition A.6. *For any inner Kan fibration $p : X \rightarrow Y$ under T , the morphism $X/_e T \rightarrow Y/_e \times_{i^*(Y)} i^*(X)$ is a right fibration of simplicial sets.*

In particular, for any ∞ -operad X under T , the map $X/_e T \rightarrow i^(X)$ is a right fibration between ∞ -categories.*

Proof. This follows from Proposition A.5 by a standard adjunction argument. \square

Theorem A.7. *Let S be a tree with at least two vertices, let v be a unary top vertex in S , and let $p : X \rightarrow Y$ be an inner Kan fibration between ∞ -operads. Then any solid commutative square of the form*

$$\begin{array}{ccc} \Lambda^v[S] & \xrightarrow{\varphi} & X \\ \downarrow & \nearrow h & \downarrow p \\ \Omega[S] & \xrightarrow{\psi} & Y \end{array}$$

in which $\varphi(v)$ is weakly invertible in X has a diagonal filling h .

Proof. The tree S has to be of shape $S = 1 \star_e T$ for a tree T with a given leaf e . Under this identification, we have $\Lambda^v[S] = \Lambda^0[1 \star_e T]$. A lifting h in the solid commutative square

$$\begin{array}{ccc} \Lambda^0[1 \star_e T] & \xrightarrow{\varphi} & X \\ \downarrow & \nearrow h & \downarrow p \\ \Omega[1 \star_e T] & \xrightarrow{\psi} & Y \end{array}$$

is thus equivalent to a lifting k in the diagram

$$\begin{array}{ccc} \{0\} & \xrightarrow{\tilde{\varphi}} & P \\ \downarrow & \nearrow k & \downarrow \\ \Delta[1] & \xrightarrow{\tilde{\psi}} & Q \end{array}$$

in which $P = X/eT$ and $Q = U \times_W V$, with

$$U = \varprojlim_R X/eR, \quad V = Y/eT, \quad W = \varprojlim_R Y/eR,$$

where R ranges over all the proper e -admissible faces of T . As in the proof of Theorem 4.2, it is now sufficient to prove the three following properties:

- (i) the map $P \rightarrow Q$ is a right fibration;
- (ii) Q is an ∞ -category.
- (iii) if $\varphi(x)$ is weakly invertible in X , then so is the 1-cell $\tilde{\psi}$ in Q .

Properties (ii) and (iii) will follow from the two assertions below:

- (iv) the map $V \rightarrow W$ is a right fibration;
- (v) the map $U \rightarrow i^*(X)$ is a right fibration.

As (iv) is a particular case of (i), we are thus reduced to prove (i) and (v).

A.7.1. *Proof of (i).*

A lifting problem of shape

$$\begin{array}{ccc} \Lambda^i[n] & \longrightarrow & P \\ \downarrow & \nearrow & \downarrow \\ \Delta[n] & \longrightarrow & Q \end{array} \quad 0 < i \leq n$$

is equivalent to a lifting problem of shape

$$\begin{array}{ccc} C & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow p \\ \Omega[n \star_e T] & \longrightarrow & Y \end{array}$$

where C is the union of $\Lambda^i[n] \star_e T$ with the union of the faces of $\Omega[n \star_e T]$ which are of the form $n \star_e S \rightarrow n \star_e T$, where S ranges over the e -admissible elementary faces of T . In other words, $C = \Lambda^i[n \star_e T]$ is an inner horn, so that the required lifting exists, because p is assumed to be an inner Kan fibration.

A.7.2. *Proof of (v).*

A lifting problem of shape

$$\begin{array}{ccc} \Lambda^i[n] & \longrightarrow & U \\ \downarrow & \nearrow & \downarrow \\ \Delta[n] & \longrightarrow & i^*(X) \end{array} \quad 0 < i \leq n$$

is equivalent to a lifting problem of shape

$$\begin{array}{ccc} C & \longrightarrow & X \\ \downarrow & \nearrow & \\ D & & \end{array}$$

in which the inclusion $C \longrightarrow D$ can be described as follows:

$$C = \Omega[n] \cup \bigcup_R \Lambda^i[n] \star_e R \subset D = \bigcup_R \Omega[n \star_e R] \subset \Omega[n \star_e T],$$

where R ranges over the e -admissible elementary faces of T . It is easily seen that the inclusion $C \longrightarrow D$ is an inner anodyne extension by Lemma A.4. \square

APPENDIX B. ANOTHER SUBDIVISION OF CYLINDERS

B.1. We will refer to the horn inclusions of shape $\Lambda^x[S] \longrightarrow \Omega[S]$, where S is a tree with a unary top vertex x , as *end extensions*. A composition of pushouts of end extensions will be called an *end anodyne* map.

The goal of this section is to prove a dual version of Theorem 5.2, namely:

Theorem B.2. *Let T be a tree with at least one vertex, and consider the subobject*

$$B_0 = \{0\} \otimes \Omega[T] \cup \Delta[1] \otimes \partial\Omega[T] \subset \Delta[1] \otimes \Omega[T].$$

There exists a filtration of $\Delta[1] \otimes \Omega[T]$ of the form

$$B_0 \subset B_1 \subset \dots \subset B_{N-1} \subset B_N = \Delta[1] \otimes \Omega[T]$$

where, for each i , $0 \leq i < N$, the map $B_i \longrightarrow B_{i+1}$ is either inner anodyne or end anodyne.

Moreover, the end anodyne maps are all push outs of the form

$$\begin{array}{ccc} \Lambda^v[S] & \longrightarrow & B_i \\ \downarrow & & \downarrow \\ \Omega[S] & \longrightarrow & B_{i+1} \end{array}$$

with the following properties:

- (i) *the tree S has at least two vertices, and v is a unary top vertex;*
- (ii) *the map*

$$\Delta[1] \longrightarrow \Lambda^v[S] \longrightarrow B_i \subset \Delta[1] \otimes \Omega[T],$$

corresponding to the vertex v in S , coincides with an inclusion of shape

$$\Delta[1] \otimes \{t\} \longrightarrow \Delta[1] \otimes \Omega[T]$$

for some edge t in T .

B.3. As in the proof of Theorem 5.2, we will follow the convention of [MW09], and write

$$\Omega[S] \otimes \Omega[T] = \bigcup_{i=1}^m \Omega[T_i],$$

where the union ranges over the partially ordered set of percolation schemes, starting with a number of copies of T grafted on top of S , and ending with the reverse grafting. For

$$S = [1] = \begin{array}{c} | \\ \circ \\ | \end{array},$$

the first tree is of shape

$$(B.3.1) \quad T_1 = \begin{array}{c} \diagup \quad \diagdown \\ \quad \bullet \quad T \\ \quad | \\ \quad \circ \\ \quad | \end{array},$$

and the last one is

$$(B.3.2) \quad T_m = \begin{array}{c} \circ \quad \circ \quad \dots \quad \circ \quad \circ \\ | \quad | \quad \dots \quad | \quad | \\ \diagdown \quad \dots \quad \diagup \\ \quad \bullet \quad T \\ \quad | \end{array}.$$

Let us fix a linear order on the percolation schemes for $\Delta[1] \otimes \Omega[T]$ which extends the natural partial order. Such a linear ordering induces a filtration on the tensor product $\Delta[1] \otimes \Omega[T]$,

$$(B.3.3) \quad C_0 \subset C_1 \subset \dots \subset C_{m-1} \subset C_m = \Delta[1] \otimes \Omega[T]$$

by setting

$$(B.3.4) \quad C_0 = B_0 = \{0\} \otimes \Omega[T] \cup \Delta[1] \otimes \partial\Omega[T] \text{ and } C_i = B_0 \cup \Omega[T_1] \cup \dots \cup \Omega[T_i].$$

the filtration of Theorem B.2 will be a refinement of this one.

Let us start by considering T_1 . If the root edge of T is called r , then T_1 looks like

$$(B.3.5) \quad \begin{array}{c} \vdots \quad \vdots \quad \vdots \quad \vdots \\ \diagdown \quad \dots \quad \diagup \\ \quad \bullet \quad (0,r) \\ \quad | \\ \quad \circ \quad (1,r) \\ \quad | \end{array}$$

With the exception of the faces $\partial_{(0,r)}(T_1)$ (which contracts $(0,r)$) and $\partial_{(1,r)}(T_1)$ (which chops off $(1,r)$ as well as the white vertex), any face F of T_1 misses a colour of T (by this, we mean there is an edge a in T such that no edge in F is named (i,a)). Hence, $\Omega[F] \subset \Delta[1] \otimes \partial\Omega[T]$ for these F . Moreover, $\partial_{(1,r)}(T_1) = \{0\} \otimes T_1$. So $\Omega[T_1] \cap B_0 = \Lambda^{(0,r)}[T_1]$, and

$$(B.3.6) \quad \begin{array}{ccc} \Lambda^{(0,r)}[T_1] & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ \Omega[T_1] & \longrightarrow & B_0 \cup \Omega[T_1] \end{array}$$

is a pushout. So, if we let $B_1 = C_1$, then $B_0 \longrightarrow B_1$ is obviously inner anodyne.

Suppose we have defined a filtration up to some B_l

$$(B.3.7) \quad B_0 \subset B_1 \subset \dots \subset B_l \quad l \geq 1,$$

so that $B_l = C_k$ for some k , $1 \leq k \leq m$. We will extend this filtration as $B_l \subset B_{l+1} \subset \dots \subset B_{l'}$, so that $B_{l'} = C_{k+1}$. The percolation scheme T_{k+1} is obtained from an earlier one T_j by pushing a white vertex in T_j one step up through a black vertex x , as in

$$(B.3.8) \quad \begin{array}{ccc} \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \bullet \\ x \\ | \\ \circ \\ \text{---} \end{array} & \Longrightarrow & \begin{array}{c} \diagup \quad \diagdown \\ \circ \quad \circ \\ \text{---} \\ \bullet \\ x \\ | \\ \text{---} \end{array} \\ \text{in } T_j & & \text{in } T_{k+1} \end{array}$$

(we have denoted by x the black vertex in both trees, although it would be more accurate to write x for the relevant vertex of T , and write $0 \otimes x$ and $1 \otimes x$ for the corresponding vertices in T_j and T_{k+1} respectively). The Boardman-Vogt relation states that, as subobjects of $\Delta[1] \otimes \Omega[T]$, the face of T_{k+1} obtained by contracting all input edges of x coincides with the face of T_j obtained by contracting the output edge of x in T_j . In particular, notice that if x has no input edges at all (i.e. if x is a ‘nullary operation’ in T), then T_{k+1} is a face of T_j , so $C_{k+1} = C_k$, and we let $B_{l'} = B_l$, and there is nothing to prove. Therefore, from now on, we will assume that the set of input edges of x , denoted $\text{input}(x)$, is non-empty, and we proceed as follows.

Let E be the set of all colours (edges) e in T for which

$$(B.3.9) \quad \begin{array}{c} \circ \\ | \\ \circ \end{array} \begin{array}{l} (0,e) \\ (1,e) \end{array}$$

occurs in T_{k+1} . For $U \subset E$, let

$$(B.3.10) \quad T_{k+1}^{(U)} \subset T_{k+1}$$

be the face given by contracting all the edges $(1, e)$ for $e \in E$ but e not in U . Notice that if $U \cap \text{input}(x) = \emptyset$, then $\Omega[T_{k+1}^{(U)}] \subset B_l$ by the Boardman-Vogt relation just mentioned. Therefore, we will only consider U with $U \cap \text{input}(x) \neq \emptyset$. We will successively adjoin $\Omega[T_{k+1}^{(U)}]$ to B_l for larger and larger such U , until we reach the case where $U = E$ and $T_{k+1}^{(U)} = T_{k+1}$.

If $U = \{e\}$ is a singleton (with e an input edge of x), then the face $\partial_{(1,e)}\Omega[T_{k+1}^{\{\{e\}\}}]$ is contained in B_l as said, while the face $\partial_{(0,e)}\Omega[T_{k+1}^{\{\{e\}\}}]$ is not (it cannot belong to an earlier T_i , and is obviously not contained in $B_0 = C_0$). Any other face of $T_{k+1}^{\{\{e\}\}}$ misses a colour of T and hence is contained in B_0 . Thus,

$$(B.3.11) \quad \Omega[T_{k+1}^{\{\{e\}\}}] \cap B_l \subset \Omega[T_{k+1}^{\{\{e\}\}}]$$

is either an inner horn (if $(0, e)$ is an inner edge of T_{k+1}) or an end extension (if $(1, e)$ is an input edge of T_{k+1}). In either case, we can adjoin $\Omega[T_{k+1}^{\{\{e\}\}}]$ by forming

the pushout below.

$$(B.3.12) \quad \begin{array}{ccc} \Omega[T_{k+1}^{\{\{e\}\}}] \cap B_l & \longrightarrow & B_l \\ \downarrow & & \downarrow \\ \Omega[T_{k+1}^{\{e\}}] & \longrightarrow & \Omega[T_{k+1}^{\{\{e\}\}}] \cup B_l \end{array}$$

We successively adjoin $\Omega[T_{k+1}^{\{\{e\}\}}]$ to B_l in this way for all e in E which are input edges of x in T : if these are e_1, \dots, e_p , let

$$(B.3.13) \quad B_{l+r} = B_l \cup \Omega[T_{k+1}^{\{\{e_1\}\}}] \cup \dots \cup \Omega[T_{k+1}^{\{\{e_r\}\}}].$$

Then, for each $r < p$, the map $B_{l+1} \longrightarrow B_{l+r+1}$ is inner anodyne or end anodyne.

In general, we proceed by induction on U . Choose $U \subset E$ with $U \cap \text{input}(x) \neq \emptyset$, and assume we have adjoined $\Omega[T_{k+1}^{(U')}]$ already, for all U' of smaller cardinality than U . We will write $B_{l'}$ for the last object in the filtration constructed up to that point. Fix an order on the set of elements of U , and write it as

$$(B.3.14) \quad U = \{\alpha_1, \dots, \alpha_s\}.$$

Consider $\Omega[T_{k+1}^{(U)}]$. The tree $T_{k+1}^{(U)}$ has edges $(0, c)$ or $(1, c)$ for c not in E , and the corresponding face misses the colour c altogether, hence $\partial_{(i,c)}\Omega[T_{k+1}^{(U)}]$ is contained in B_0 for these c . Next, the tree $T_{k+1}^{(U)}$ has edges coloured $(1, \alpha_i)$ for $1 \leq i \leq s$, and contracting any of these gives a face

$$(B.3.15) \quad \partial_{(1,\alpha_i)}\Omega[T_{k+1}^{(U)}] = \Omega[T_{k+1}^{(U-\{\alpha_i\})}]$$

which is contained in $B_{l'}$ by the inductive assumption on U . None of the faces given by contracting (if it is inner) or by chopping off (if it is outer) an edge $(0, \alpha_i)$ in $T_{k+1}^{(U)}$ can be contained in $B_{l'}$, however.

Let A_1, \dots, A_t be all the subsets of the set of these edges $\{(0, \alpha_1), \dots, (0, \alpha_s)\}$ of $T_{k+1}^{(U)}$ which contain $(0, \alpha_1)$, and order them by some linear order extending the inclusion order. So there are $t = 2^{s-1}$ such A_i , and we could fix the order to be

$$\begin{aligned} A_1 &= \{(0, \alpha_1)\} \\ A_2 &= \{(0, \alpha_1), (0, \alpha_2)\} \\ &\vdots \\ A_s &= \{(0, \alpha_1), (0, \alpha_s)\} \\ A_{s+1} &= \{(0, \alpha_1), (0, \alpha_2), (0, \alpha_3)\} \\ &\vdots \\ A_t &= \{(0, \alpha_1), \dots, (0, \alpha_s)\}. \end{aligned}$$

For $q = 1, \dots, t$, let $T_{k+1}^{(U,q)}$ be the tree obtained from $T_{k+1}^{(U)}$ by contracting or chopping off all the edges $(0, \alpha_i)$ not in A_q . So

$$(B.3.16) \quad T_{k+1}^{(U,1)} = \partial_{(0,\alpha_s)}\partial_{(0,\alpha_{s-1})} \cdots \partial_{(0,\alpha_2)}T_{k+1}^{(U)},$$

and

$$(B.3.17) \quad T_{k+1}^{(U,t)} = T_{k+1}^{(U)}.$$

We will successively adjoin these $\Omega[T_{k+1}^{(U,q)}]$ to the filtration, to form the part

$$(B.3.18) \quad B_{l''} \subset B_{l''+1} \subset \dots \subset B_{l''+t} = B_{l''} \cup \Omega[T_{k+1}^{(U)}]$$

of the filtration, as

$$(B.3.19) \quad B_{l''+q} = B_{l''} \cup \Omega[T_{k+1}^{(U,1)}] \cup \dots \cup \Omega[T_{k+1}^{(U,q)}].$$

We start with $T_{k+1}^{(U,1)}$. The only face of $\Omega[T_{k+1}^{(U,1)}]$ not contained in $B_{l''}$ is the one given by the edge $(0, \alpha_1)$. Thus

$$(B.3.20) \quad \Omega[T_{k+1}^{(U,1)}] \cap B_{l''} \subset \Omega[T_{k+1}^{(U,1)}]$$

is either an inner horn (if $(0, \alpha_1)$ is an inner edge) or an end extension (if $(0, \alpha_1)$ is an input edge of $T_{k+1}^{(U)}$, i.e. α_1 is an input edge of T). So the pushout $B_{l''} \longrightarrow B_{l''+1}$ is either inner anodyne or end anodyne.

Suppose we have adjoined $\Omega[T_{k+1}^{(U,q')}]$ for all $1 \leq q' < q$, so have arrived at the stage $B_{l''+q-1}$ of the filtration. Consider now A_q and the corresponding dendroidal set $\Omega[T_{k+1}^{(U,q)}]$. As before, its faces given by edges coloured by (i, c) for $i = 0, 1$ with c not in E are contained in B_0 , and its faces given by edges coloured $(1, e)$ with $e \in U$ are contained in $\Omega[T_{k+1}^{(U')}]$ for a smaller $U' = U - \{e\}$, hence are contained in $B_{l''}$. Let us consider the remaining faces given by the edges $(0, \alpha_1), \dots, (0, \alpha_r)$ in A_q . If $i \neq 1$, the face of $\Omega[T_{k+1}^{(U,q)}]$ given by $(0, \alpha_i) \in A_q$ is contained in $\Omega[T_{k+1}^{(U,q')}]$ for some $q' < q$ with $A_{q'} = A_q - \{(0, \alpha_i)\}$. So the only face that is missing is the one given by $(0, \alpha_1)$, i.e.

$$(B.3.21) \quad \Omega[T_{k+1}^{(U,q)}] \cap B_{l''+q-1} = \Lambda^{(0, \alpha_1)}[T_{k+1}^{(U,q)}].$$

Therefore, the induced pushout $B_{l''+q-1} \longrightarrow B_{l''+q}$ is either inner anodyne or end anodyne (depending on whether α_1 is an external edge of T or not). At the end, when $q = t$, we have adjoined all of $\Omega[T_{k+1}^{(U)}]$.

This completes the construction of the segment of the filtration for the subset $U \subset E$. As said, we continue this construction until we reach the stage $U = E$, when $T_{k+1}^{(U)} = T_{k+1}$, which completes the construction of the segment of the filtration from B_l until $B_{l'}$, interpolating between C_k and C_{k+1} . This completes the description of the filtration. From it, the last part of the theorem is clear.
