HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

CLIFFORD STRUCTURES ON RIEMANNIAN MANIFOLDS

ANDREI MOROIANU AND UWE SEMMELMANN

ABSTRACT. Motivated by considerations on curvature constancy and fat bundles, we introduce the notion of rank r even Clifford structures on Riemannian manifolds, which for $r = 2$ and $r = 3$ reduce to Kähler and quaternion-Kähler structures respectively. We give the complete classification of manifolds carrying parallel rank r even Clifford structures: Riemannian products of quaternion-Kähler manifolds for $r = 4$, several classes of 8-dimensional manifolds (for $5 \leq r \leq 8$), families of real, complex and quaternionic Grassmannians (for $r = 8, 6$ and 5 respectively), and Rosenfeld's elliptic projective planes $\mathbb{O}\mathbb{P}^2$, $(\mathbb{C} \otimes \mathbb{O})\mathbb{P}^2$, $(\mathbb{H} \otimes \mathbb{O})\mathbb{P}^2$ and $(\mathbb{O} \otimes \mathbb{O})\mathbb{P}^2$, which are symmetric spaces associated to the exceptional simple Lie groups F_4 , E_6 , E_7 and E_8 (for $r = 9, 10, 12$ and 16 respectively). As an application, we classify all Riemannian manifolds whose metric is bundle-like along the curvature constancy distribution, generalizing well-known results in Sasakian and 3-Sasakian geometry.

2000 *Mathematics Subject Classification*: Primary 53C26, 53C35, 53C10, 53C15.

Keywords: Clifford structure, Kähler, quaternion-Kähler, symmetric spaces, exceptional Lie groups, Rosenfeld's elliptic projective planes, curvature constancy, fat bundles.

1. INTRODUCTION

The curvature constancy on a Riemannian manifold (Z, g_Z) is a notion introduced by Gray in the 60's [10] under the somewhat improper terminology of *curvature nullity*. Roughly speaking, a tangent vector X belongs to the curvature constancy \mathcal{V} if its contraction with the Riemannian curvature tensor R^Z equals its contraction with the algebraic curvature tensor of the round sphere, c.f. (9) below. One reason why Gray was interested in this notion is that on the open set of Z where the dimension of the curvature constancy achieves its minimum, \mathcal{V} is a totally geodesic distribution whose integral leaves are locally isomorphic to the round sphere.

Typical examples of manifolds with non-trivial curvature constancy are Sasakian and 3-Sasakian manifolds, the dimension of \mathcal{V} being (generically) 1 and 3 respectively. Rather curiously, Gray seems to have overlooked these examples when he conjectured in [10] that if the curvature constancy of a Riemannian manifold (Z, g_Z) is non-trivial, then the manifold is locally isometric to the round sphere. By the above, this conjecture is clearly false, but one may wonder whether counter-examples, other than Sasakian and 3-Sasakian structures, do exist.

Date: December 21, 2009.

This work was supported by the French-German cooperation project Procope no. 17825PG.

One of the goals of this paper is to classify Riemannian manifolds Z admitting non-trivial curvature constancy \mathcal{V} under the additional assumption that the metric is *bundle-like* along the distribution \mathcal{V} , i.e. such that Z is locally the total space of a Riemannian submersion $Z \rightarrow M$ whose fibres are the integral leaves of \mathcal{V} , c.f. Theorem 3.5. Notice that Sasakian and 3-Sasakian manifolds have this property, being total spaces of (locally defined) Riemannian submersion over Kähler and quaternion-Kähler manifolds respectively.

Bundle-like metrics with curvature constancy also occur as a special case of *fat bundles*, introduced by Weinstein in [19] and recently revisited by Ziller (c.f. [20]). A Riemannian submersion is called fat if the sectional curvature is positive on planes spanned by a horizontal and a vertical vector. Homogeneous fat bundles were classified by Bérard-Bergery in [4]. It turns out that all our homogeneous examples with curvature constancy (c.f. Table 3) may be found in his list. It is still an open question whether there are examples of non-homogeneous fat bundles with fibre dimension larger than one (c.f. [20]).

The proof of the classification of bundle-like metrics with curvature constancy goes roughly as follows. We first show that every Riemannian submersion $Z \rightarrow M$ with totally geodesic k -dimensional fibres is associated to a G -principal bundle $P \rightarrow M$ (where G is the isometry group of some given fibre), which carries a canonical G -invariant connection. The curvature of this connection is a 2-form ω on M with values in the adjoint bundle $\text{ad}(P)$. We then compute the different components of the Riemannian curvature tensor of Z in terms of the Riemannian curvature of M and of the curvature form ω . We interpret the curvature constancy condition by the fact that ω defines a *parallel even Clifford structure* on M , which is in some sense dual to the notion of spin structure: In contrast to the spin bundle, which is a representation of the Clifford bundle of TM , a rank r (even) Clifford structure is a rank r Euclidean vector bundle E whose (even) Clifford algebra bundle acts on the tangent bundle TM . The structure is called parallel if the action is parallel with respect to some metric connection on E . For $r = 2$ and $r = 3$ this reduces to the well-known notions of Kähler and quaternion-Kähler structures respectively.

The core of the paper consists of the classification of manifolds carrying (even) Clifford structures, c.f. Theorem 4.10. We obtain Riemannian products of quaternion-Kähler manifolds for $r = 4$, several classes of 8-dimensional manifolds (for $5 \leq r \leq 8$), families of real, complex and quaternionic Grassmannians (for $r = 8, 6$ and 5 respectively), and Rosenfeld's elliptic projective planes $\mathbb{O}\mathbb{P}^2$, $(\mathbb{C} \otimes \mathbb{O})\mathbb{P}^2$, $(\mathbb{H} \otimes \mathbb{O})\mathbb{P}^2$ and $(\mathbb{O} \otimes \mathbb{O})\mathbb{P}^2$, which are symmetric spaces associated to the exceptional simple Lie groups F_4, E_6, E_7 and E_8 (for $r = 9, 10, 12$ and 16 respectively). In the last section we classify manifolds carrying parallel Clifford structures (Theorem 6.3).

Several attempts to define the concept of Clifford structures on Riemannian manifolds can be found in the literature. We thus stress on the somewhat unfortunate fact that the same terminology is used for different notions. Some authors have introduced it as a family of complex structures satisfying the Clifford relations, i.e. as a representation of the Clifford algebra on the tangent bundle. Manifolds with many complex structures are also interesting in physics, e.g. it is known for the 2-dimensional supersymmetric σ -model, that a target manifold with $N - 1$ independent parallel anti-commuting complex structures gives rise to

N supersymmetries. Spindel et al. studied in [18] Clifford structures on group manifolds and proved the restriction $N \leq 4$, which later was found to be wrong in the non-compact case (c.f. [13]). Joyce gives in [13] a construction method for manifolds with arbitrarily large Clifford structures. At the same time Barberis et al. constructed in [3] Clifford structures on compact flat manifolds, e.g. using 2-step nilpotent Lie groups. Another notion of Clifford structures was used in connection with the Osserman Conjecture. Following ideas of Gilkey, Nikolayevsky defines in [16] Clifford structures on Riemannian manifolds with an additional assumption on the Riemannian curvature tensor. The only author who comes close to our concept of even Clifford structure is Burdujan. He considers in [6] and [7] so-called *Clifford-Kähler* manifolds, which in our notation become manifolds with a rank 5 even Clifford structure. In particular he proves that such manifolds have to be Einstein (a special case of Proposition 4.6 below).

Acknowledgments. We are indebted to P.-A. Nagy who first introduced to us the notion of curvature constancy and to W. Ziller for having shared a preliminary version of his work [20] on fat bundles with us and for several useful comments.

2. RIEMANNIAN SUBMERSIONS WITH TOTALLY GEODESIC FIBRES

In this section we collect several results and formulas for Riemannian submersions which will be used in the sequel. Most of this material can be found in the literature (c.f. [11], see also [20]), but we include it here for the convenience of the reader, as well as for introducing the notations, conventions and usual normalizations. Experts in Riemannian geometry can pass directly to the next section.

Let $\pi : Z^{k+n} \rightarrow M^n$ be a Riemannian submersion with totally geodesic fibres. Assume that Z is complete. We denote by $Z_x := \pi^{-1}(x)$ the fibre of π over $x \in M$. From Theorem 1 in [12], all fibres are isometric with some fixed Riemannian manifold (F, g_F) and π is a locally trivial fibration with structure group the Lie group $G := \text{Iso}(F)$ of isometries of F .

For every tangent vector $X \in T_x M$ and $z \in Z_x$, we denote by X^* its horizontal lift at z . For every curve γ on M and $z \in Z_{\gamma(0)}$ there exists a unique curve $\tilde{\gamma}$ with $\tilde{\gamma}(0) = z$ whose tangent vector at t is the horizontal lift of $\dot{\gamma}(t)$ at $\tilde{\gamma}(t)$ for every t . This is called the *horizontal lift* of γ through z . Hermann's result in [12] mainly says that for every curve γ on M , the mapping $\tau_t : Z_{\gamma(0)} \rightarrow Z_{\gamma(t)}$, which maps z to the value at t of the horizontal lift of γ through z , is an isometry between the two fibres, (each endowed with the induced Riemannian metric).

We define the G -principal fibre bundle P over M as the set of isometries from F to the fibres of π :

$$P := \{u : F \rightarrow Z \mid \exists x \in M \text{ such that } u \text{ maps } F \text{ isometrically onto } Z_x\}.$$

We denote by $p : P \rightarrow M$ the natural projection and by P_x the fiber of p over x :

$$P_x := \{u : F \rightarrow Z_x \mid u \text{ is an isometry}\}.$$

The right action of $G = \text{Iso}(F)$ on P is given by $ua := u \circ a$ for every $u \in P$ and $a \in G$.

Proposition 2.1. *The horizontal distribution on Z induces a G -invariant connection on P .*

Proof. For $X \in T_x M$ and $u \in P_x$, we define its *horizontal lift* $\tilde{X} \in T_u P$ as follows. Take any curve x_t in M such that $X = \dot{x}_0$. The isometry τ_t between Z_{x_0} and Z_{x_t} described above, defines a curve $u_t := \tau_t \circ u$ which obviously satisfies $p(u_t) = x_t$. We then set $\tilde{X} := \dot{u}_0$ and claim that this does not depend on the curve x_t . This is actually a direct consequence of the following more general result:

Lemma 2.2. *Let $p : P \rightarrow M$ be a G -principal fibre bundle and assume that G acts effectively on some manifold F . Define $Z := P \times_G F$ and for each $f \in F$, the smooth map $R_f : P \rightarrow Z$, $R_f(u) = u(f)$. Then a tangent vector $X \in T_u P$ vanishes if and only if $p_*(X) = 0$ and $(R_f)_*(X) = 0$ for every $f \in F$.*

Proof. Since the result is local, one may assume that $P = M \times G$ is trivial and $u = (x, 1)$. One can write $X = (X', X'')$, with $X' \in T_x M$ and $X'' \in \mathfrak{g}$. Since $p_*(X) = 0$, we get $X' = 0$. From $(R_f)_*(X) = 0$ we obtain $\exp(tX'')(f) = f$ for every $t \in \mathbb{R}$ and $f \in F$. If X'' were not zero, this would contradict the effectiveness of the action of G . \square

Returning to our argument, we see that $p_*(\tilde{X}) = X$ and

$$(R_f)_*(\tilde{X}) = \left. \frac{\partial}{\partial t} \right|_{t=0} (u_t(f)) = \left. \frac{\partial}{\partial t} \right|_{t=0} (\tau_t(u(f))) = X_{u(f)}^*$$

only depend on X , not on x_t . The map $T_x M \rightarrow T_u P$, $X \mapsto \tilde{X}$ is thus well-defined for every $x \in M$ and $u \in p^{-1}(x)$. We denote by H_u the image of this map.

Lemma 2.2 also shows that H_u is a vector subspace of $T_u P$, supplementary to the tangent space to the fibre of P through u . The collection $\{H_u, u \in P\}$ is called the horizontal distribution, and it is easy to see that it is invariant under the action of G : If $a \in G$, $u \in P$ and x_t is a curve in M with $x_0 = p(u)$, then (denoting $X := \dot{x}_0$):

$$(R_a)_*(\tilde{X}_u) = (R_a)_* \left. \frac{\partial}{\partial t} \right|_{t=0} (\tau_t \circ u) = \left. \frac{\partial}{\partial t} \right|_{t=0} (\tau_t \circ ua) = \tilde{X}_{ua}.$$

This proves the proposition. \square

We will now express the Riemannian curvature of Z in terms of the curvature of the connection on P defined above (we will denote this connection by θ in the sequel). In order to do this, we need to introduce some notation. The adjoint bundle $\text{ad}(P)$ of P , is the vector bundle associated to P via the adjoint representation of G on its Lie algebra:

$$\text{ad}(P) := P \times_{\text{ad}} \mathfrak{g},$$

where for every $g \in G$, $\text{ad}_g : \mathfrak{g} \rightarrow \mathfrak{g}$ is the differential at the identity of $\text{Ad}_g : G \rightarrow G$ defined as usually by $\text{Ad}_g(h) := ghg^{-1}$. The curvature of the connection θ defined by Proposition 2.1 is a G -equivariant 2-form $\tilde{\omega}$ on P with values in \mathfrak{g} or, equivalently, a 2-form ω on M with values in the vector bundle $\text{ad}(P)$, i.e. a section of $\Lambda^2 M \otimes \text{ad}(P)$. The forms ω and $\tilde{\omega}$ are related by

$$(1) \quad [u, \tilde{\omega}(\tilde{X}, \tilde{Y})_u] = \omega(X, Y)_{p(u)},$$

where $X, Y \in T_{p(u)} M$ are tangent vectors on M with horizontal lifts $\tilde{X}, \tilde{Y} \in T_u P$ to tangent vectors on P .

For each $x \in M$, the fibre $\text{ad}(P)_x$ of $\text{ad}(P)$ over x has a Lie algebra structure (it is actually naturally isomorphic to the Lie algebra of the isometry group of the fibre Z_x). Every element α of $\text{ad}(P)_x$ induces a Killing vector field denoted α^* on the corresponding fibre Z_x . If α is represented by $A \in \mathfrak{g}$ in the frame $u \in P_x$ (i.e. $\alpha = [u, A]$), and $z \in Z_x$ is represented by $f \in F$ in the same frame u (i.e. $z = [u, f]$), then α_z^* is the image of A by the differential at the identity of the map $G \rightarrow Z_x$, $a \mapsto [u, af]$. By a slight abuse of notation, we denote this by $\alpha_z^* = uAf$. It is easy to check that this is independent of u : If we replace u by ug , then $\alpha = [ug, \text{ad}_{g^{-1}}(A)]$, $z = [ug, g^{-1}f]$, so $\alpha_z^* = ug(g^{-1}Ag)(g^{-1}f) = uAf$.

Every section α of $\text{ad}(P)$ induces in this way a vertical vector field α^* on Z .

Definition 2.3. The vertical vector fields on Z obtained in this way from sections of $\text{ad}(P)$, and the horizontal lifts X^* of vector fields X on M are called *standard vertical and horizontal vector fields* on Z .

We will compute the Levi-Civita covariant derivative on Z in a local frame consisting of standard vertical and horizontal vector fields. We start by computing the Lie brackets.

Lemma 2.4. *If X, Y are vector fields on M and α is a section of $\text{ad}(P)$, the following relations hold:*

$$(2) \quad [X^*, \alpha^*] = (\nabla_X^\theta \alpha)^*,$$

$$(3) \quad [X^*, Y^*] = [X, Y]^* - \omega(X, Y)^*,$$

where ∇^θ is the covariant derivative on $\text{ad}(P)$ induced by the connection θ on P defined in Proposition 2.1 and ω is the curvature of θ , viewed as a 2-form on M with values in $\text{ad}(P)$.

Proof. The first relation is more or less the definition of the covariant derivative on $\text{ad}(P)$. Indeed, the flow φ_t of X^* acts on a standard vertical vector field α^* by conjugation with the parallel transport:

$$\varphi_{t*}(\alpha^*) = (\tau_t \circ \alpha \circ \tau_t^{-1})^*,$$

whence

$$(\nabla_X^\theta \alpha)^* = -\left(\frac{d}{dt}\Big|_{t=0} \tau_t \circ \alpha \circ \tau_t^{-1}\right)^* = -\frac{d}{dt}\Big|_{t=0} \varphi_{t*}(\alpha^*) = [X^*, \alpha^*].$$

In order to prove the second relation, we apply (2) and compute for every standard vertical vector field α^* using the Jacobi identity

$$\begin{aligned} [\omega(X, Y)^*, \alpha^*] &= -[\omega(X, Y), \alpha]^* = -(\nabla_X^\theta \nabla_Y^\theta \alpha - \nabla_Y^\theta \nabla_X^\theta \alpha - \nabla_{[X, Y]}^\theta \alpha)^* \\ &= -[X^*, [Y^*, \alpha^*]] + [Y^*, [X^*, \alpha^*]] + [[X^*, Y^*], \alpha^*] \\ &= [[X^*, Y^*] - [X, Y]^*, \alpha^*]. \end{aligned}$$

Note that the first equality is a consequence of the fact that for every Lie group G acting (from the left) on a manifold M , the canonical map which associates to a right-invariant vector field on G a vector field on M is a Lie algebra anti-automorphism. \square

From (3) we see that the tensor A of the O'Neill formulas for a Riemannian submersion is given by $A(X, Y) = -\frac{1}{2}\omega(X, Y)^*$ for horizontal vector fields X, Y on M . Moreover, as an

immediate corollary of (2) and (3), together with the Koszul formula describing the Levi-Civita connection we obtain:

Lemma 2.5. *If X, Y are vector fields on M and α is a section of $\text{ad}(P)$, the following relations hold:*

$$(4) \quad \nabla_{\alpha^*}^Z X^* = \frac{1}{2} \sum_{a=1}^n g_Z(\alpha^*, \omega(X, X_a)^*) X_a^*,$$

$$(5) \quad \nabla_{X^*}^Z \alpha^* = (\nabla_X^\theta \alpha)^* + \frac{1}{2} \sum_{a=1}^n g_Z(\alpha^*, \omega(X, X_a)^*) X_a^*,$$

$$(6) \quad \nabla_{X^*}^Z Y^* = (\nabla_X Y)^* - \frac{1}{2} \omega(X, Y)^*,$$

where ∇ is the Levi-Civita covariant derivative on M and $\{X_a\}$ is a local orthonormal frame on M .

We will now compute the relevant component of the curvature tensor of Z . Let X, Y be vector fields on M . We may assume that X, Y and the local orthonormal frame $\{X_a\}$ are parallel at some point $x \in M$. As before we denote with X^* the horizontal lift of X to a vector field on Z and with α^* the vertical vector field on Z corresponding to the section α of the vector bundle $\text{ad}(P)$. Using Lemma 2.5 we can write:

$$\begin{aligned} \nabla_{X^*}^Z (\nabla_{\alpha^*}^Z Y^*) &= \frac{1}{2} \sum_{a=1}^n \nabla_{X^*}^Z (g_Z(\alpha^*, \omega(Y, X_a)^*) X_a^*) \\ &= \frac{1}{2} \sum_{a=1}^n \left(g_Z(\nabla_{X^*}^Z \alpha^*, \omega(Y, X_a)^*) X_a^* + g_Z(\alpha^*, \nabla_{X^*}^Z \omega(Y, X_a)^*) X_a^* \right. \\ &\quad \left. + g_Z(\alpha^*, \omega(Y, X_a)^*) \nabla_{X^*}^Z X_a^* \right) \\ &= \frac{1}{2} \sum_{a=1}^n \left(g_Z((\nabla_X^\theta \alpha)^*, \omega(Y, X_a)^*) X_a^* + g_Z(\alpha^*, ((\nabla_X^\theta \omega)(Y, X_a))^*) X_a^* \right. \\ &\quad \left. - \frac{1}{2} g_Z(\alpha^*, \omega(Y, X_a)^*) \omega(X, X_a)^* \right), \end{aligned}$$

$$\nabla_{\alpha^*}^Z (\nabla_{X^*}^Z Y^*) = \nabla_{\alpha^*}^Z ((\nabla_X Y)^* - \frac{1}{2} \omega(X, Y)^*) = -\frac{1}{2} \nabla_{\alpha^*}^Z \omega(X, Y)^*,$$

$$\nabla_{[X^*, \alpha^*]}^Z Y^* = \nabla_{(\nabla_X^\theta \alpha)^*}^Z Y^* = \frac{1}{2} \sum_{a=1}^n g_Z((\nabla_X^\theta \alpha)^*, \omega(Y, X_a)^*) X_a^*.$$

Consequently,

$$\begin{aligned} R_{X^*, \alpha^*}^Z Y^* &= \frac{1}{2} \sum_{a=1}^n g_Z(\alpha^*, ((\nabla_X^\theta \omega)(Y, X_a))^*) X_a^* - \frac{1}{4} \sum_{a=1}^n g_Z(\alpha^*, \omega(Y, X_a)^*) \omega(X, X_a)^* \\ &\quad + \frac{1}{2} \nabla_{\alpha^*}^Z \omega(X, Y)^*. \end{aligned}$$

Taking the scalar product in this equation with a horizontal vector T^* and a vertical vector β^* , yields

$$(7) \quad g_Z(R_{X^*, \alpha^*}^Z Y^*, T^*) = \frac{1}{2} g_Z(\alpha^*, ((\nabla_X^\theta \omega)(Y, T))^*),$$

$$(8) \quad \begin{aligned} g_Z(R_{X^*, \alpha^*}^Z Y^*, \beta^*) &= -\frac{1}{4} \sum_{a=1}^n g_Z(\alpha^*, \omega(Y, X_a)^*) g_Z(\beta^*, \omega(X, X_a)^*) \\ &\quad + \frac{1}{2} g_Z(\beta^*, \nabla_{\alpha^*}^Z \omega(X, Y)^*). \end{aligned}$$

Note that (7) and (8) are special cases of the O'Neill curvature equations for Riemannian submersions (c.f. [5]).

3. CURVATURE CONSTANCY

Let (Z, g_Z) be a Riemannian manifold. For every $z \in Z$ we define the curvature constancy at z by (see [10]):

$$(9) \quad \mathcal{V}_z := \{V \in T_z Z \mid R_{V, X}^Z Y = g_Z(X, Y)V - g_Z(V, Y)X \text{ for every } X, Y \in T_z Z\}.$$

The function $z \mapsto \dim(\mathcal{V}_z)$ is upper semi-continuous on Z . By replacing Z with the open subset where this function attains its minimum, we may assume that \mathcal{V} is a k -dimensional distribution on Z , called the *curvature constancy*. It is easy to check that \mathcal{V} is totally geodesic (c.f. [10]).

We will introduce the following Ansatz in order to study the curvature constancy condition: Assume that \mathcal{V} is locally the vertical distribution of a Riemannian submersion $\pi : Z \rightarrow M$ (equivalently, the metric of Z is bundle-like along \mathcal{V}). Since \mathcal{V} is totally geodesic, the fibres of the Riemannian submersion are locally isometric to the unit sphere \mathbb{S}^k . All computations below being local, we can assume, by restricting to a contractible neighbourhood M' of M and taking the universal cover of $\pi^{-1}(M')$, that each fibre is globally isometric to \mathbb{S}^k . Consider the G -principal fibre bundle P over M defined in the previous section, together with the connection θ given by Proposition 2.1. We set $k+1 =: r$ so $G = \text{SO}(r)$, and introduce the rank r Euclidean vector bundle $E \rightarrow M$ associated to P via the standard representation of $\text{SO}(r)$. Notice that $\text{ad}(P)$ is naturally identified with the bundle $\text{End}^-(E)$ of skew-symmetric endomorphisms of E , and Z is identified with the unit sphere bundle of E .

The curvature constancy condition (9) can be expressed in terms of standard vertical and horizontal vector fields as follows:

$$(10) \quad R_{\alpha^*, X^*}^Z Y^* = g_M(X, Y)\alpha^* \quad \text{for every } X, Y \in TM, \alpha \in \text{ad}(P).$$

Using (7) and (8), this is equivalent to the system

$$(11) \quad (\nabla_X^\theta \omega)(Y, T) = 0, \quad \forall X, Y, T \in TM,$$

$$(12) \quad g_M(X, Y)g_Z(\alpha^*, \beta^*) = \frac{1}{4} \sum_{a=1}^n g_Z(\alpha^*, \omega(Y, X_a)^*) g_Z(\beta^*, \omega(X, X_a)^*) \\ - \frac{1}{2} g_Z(\beta^*, \nabla_{\alpha^*}^Z \omega(X, Y)^*),$$

for all $X, Y \in TM$ and $\alpha, \beta \in \text{ad}(P)$. In order to exploit (12), we need to express the scalar product and covariant derivative of standard vertical vector fields in terms of the corresponding objects on E .

Lemma 3.1. *For every $z \in Z \subset E$ and $\alpha, \beta, \gamma \in \text{ad}(P) = \text{End}^-(E)$ in the fibre over $x := \pi(z)$ we have*

$$(13) \quad g_Z(\alpha^*, \beta^*)_z = g_E(\alpha z, \beta z).$$

$$(14) \quad g_Z(\nabla_{\alpha^*}^Z \gamma^*, \beta^*)_z = g_E(\gamma \alpha z, \beta z).$$

Proof. Any frame u of P defines an isometry from (E_x, g_E) to the standard Euclidean space \mathbb{R}^r . Once we fix such a frame, $\text{ad}(P)_x$ becomes the space of skew-symmetric matrices, Z_x is the unit sphere in \mathbb{R}^r , and the vertical vector field α^* associated to a skew-symmetric matrix $\alpha \in \mathfrak{so}(r)$ is the Killing vector field on \mathbb{S}^{r-1} whose value at $z \in \mathbb{S}^{r-1} \subset \mathbb{R}^r$ is $\alpha z \in T_z \mathbb{S}^{r-1}$. The first formula is now clear.

The Levi-Civita covariant derivative on \mathbb{S}^{r-1} is the projection of the directional derivative in \mathbb{R}^r . Moreover, the derivative of the vector-valued function $f(z) = z$ on \mathbb{R}^r obviously satisfies $A.f = A$ for every tangent vector $A \in T\mathbb{R}^r$. We thus get at z :

$$g_Z(\nabla_{\alpha^*}^Z \gamma^*, \beta^*)_z = g_E(\alpha z \cdot \gamma f, \beta z) = g_E(\gamma \alpha z, \beta z).$$

□

Taking Lemma 3.1 into account, (12) is equivalent to

$$(15) \quad g_M(X, Y)g_E(\alpha z, \beta z) = \frac{1}{4} \sum_{a=1}^n g_E(\alpha z, \omega(Y, X_a)z) g_E(\beta z, \omega(X, X_a)z) \\ - \frac{1}{2} g_E(\beta z, \omega(X, Y)\alpha z),$$

for all $z \in Z = S(E)$, $\alpha, \beta \in \text{ad}(P) = \text{End}^-(E)$ and $X, Y \in TM$.

Formula (15) can be equivalently stated as follows:

$$(16) \quad g_M(X, Y)g_E(v_1, v_2) = \frac{1}{4} \sum_{a=1}^n g_E(v_1, \omega(Y, X_a)u) g_E(v_2, \omega(X, X_a)u) - \frac{1}{2} g_E(v_2, \omega(X, Y)v_1),$$

for all $u, v_1, v_2 \in E_x$ with $|u|_E^2 = 1$ and $v_1, v_2 \perp u$ and for all $X, Y \in T_x M$. We introduce the map $\varphi : \Lambda^2 E \rightarrow \text{End}^-(TM)$, defined by

$$g_M(\varphi(u \wedge v)X, Y) := -\frac{1}{2}g_E(v, \omega(X, Y)u), \quad \forall x \in M, u, v \in E_x, X, Y \in T_x M.$$

Formula (16) is then equivalent to

$$(17) \quad \varphi(u \wedge v) \circ \varphi(u \wedge w) = \varphi(v \wedge w) - g_E(v, w)\text{id},$$

for all $u, v, w \in E_x$ with $|u|_E^2 = 1$ and $v, w \perp u$ (where id denotes the identity of $T_x M$).

We will interpret this relation as the universality property of the even Clifford algebra.

Lemma 3.2. *Let (V, h) be a Euclidean vector space and let \mathcal{A} be any real algebra with unit. We make the usual identification of $\Lambda^2 V$ with a subspace of $\text{Cl}^0(V, h)$. Then there exists a linear map $\varphi : \Lambda^2 V \rightarrow \mathcal{A}$ satisfying*

$$(18) \quad \varphi(u \wedge v) \circ \varphi(u \wedge w) = \varphi(v \wedge w) - h(v, w)1_{\mathcal{A}}$$

for all $u, v, w \in V$ with $|u|_V^2 = 1$ and $v, w \perp u$ if and only if φ extends to an algebra morphism $\varphi : \text{Cl}^0(V, h) \rightarrow \mathcal{A}$.

Proof. The ‘‘if’’ part is obvious. Conversely, let $u, v, w \in V$ be arbitrary vectors. We apply (18) to the triple $\tilde{u} := u/|u|$, $\tilde{v} := v - h(u, v)u/|u|^2$ and $\tilde{w} := w - h(u, w)u/|u|^2$ and obtain

$$(19) \quad \begin{aligned} \varphi(u \wedge v) \circ \varphi(u \wedge w) &= |u|^2 \varphi(v \wedge w) - h(u, v)\varphi(u \wedge w) - h(u, w)\varphi(v \wedge u) \\ &\quad - (|u|^2 h(v, w) - h(u, v)h(u, w))1_{\mathcal{A}}. \end{aligned}$$

By defining $\sigma : V \otimes V \rightarrow \mathcal{A}$, $u \otimes v \mapsto \sigma_{uv} := \varphi(u \wedge v) - h(u, v)1_{\mathcal{A}}$, (19) becomes equivalent to

$$(20) \quad \sigma_{uv} + \sigma_{vu} = -2h(u, v)1_{\mathcal{A}},$$

$$(21) \quad \sigma_{vu} \circ \sigma_{uw} = -h(u, u)\sigma_{vw}$$

for all $u, v, w \in V$. Let $T(V)$ denote the tensor algebra of V and

$$T^0(V) := \bigoplus_{k \geq 0} V^{\otimes 2k}.$$

By definition, $\text{Cl}^0(V, h) = T^0(V)/\mathcal{I}$, where \mathcal{I} is the intersection with $T^0(V)$ of the two-sided ideal of $T(V)$ generated by elements of the form $u \otimes u + h(u, u)$. The map σ clearly induces a unique algebra morphism $\sigma^* : T^0(V) \rightarrow \mathcal{A}$ such that $\sigma^* = \sigma$ on $V \otimes V$. We claim that $\mathcal{I} \subset \text{Ker}(\sigma^*)$. Now, every element of \mathcal{I} is a linear combination of elements of the form $A = a \otimes (u \otimes u + h(u, u)) \otimes b$ or $B = a \otimes v \otimes (u \otimes u + h(u, u)) \otimes w \otimes b$, with $a, b \in T^0(V)$ and $u, v, w \in V$. From (20) we have

$$\sigma^*(A) = \sigma^*(a) \circ (\sigma_{uu} + h(u, u)1_{\mathcal{A}}) \circ \sigma^*(b) = 0,$$

and (21) yields

$$\begin{aligned} \sigma^*(B) &= \sigma^*(a) \circ \sigma^*(v \otimes u \otimes u \otimes w + h(u, u)v \otimes w) \circ \sigma^*(b) \\ &= \sigma^*(a) \circ (\sigma_{vu} \circ \sigma_{uw} + h(u, u)\sigma_{vw}) \circ \sigma^*(b) = 0. \end{aligned}$$

Consequently σ^* descends to an algebra morphism $\text{Cl}^0(V, h) \rightarrow \mathcal{A}$, whose restriction to $\Lambda^2 V$ is just φ . \square

The lemma above suggests the following

Definition 3.3. A rank r even Clifford structure ($r \geq 2$) on a Riemannian manifold (M^n, g) is an oriented rank r Euclidean bundle (E, h) over M together with a non-vanishing algebra bundle morphism, called *Clifford morphism*, $\varphi : \text{Cl}^0(E) \rightarrow \text{End}(TM)$ which maps $\Lambda^2 E$ into $\text{End}^-(TM)$.

An even Clifford structure (M, g, E, h) is called *parallel* if there exists a metric connection ∇^E on (E, h) such that φ is connection preserving, i.e.

$$(22) \quad \varphi(\nabla_X^E \sigma) = \nabla_X^g \varphi(\sigma)$$

for every tangent vector $X \in TM$ and section σ of $\text{Cl}^0(E)$ (here and henceforth ∇^g denotes the Levi-Civita connection of (M, g)).

Remark 3.4. For r even, the notion of even Clifford structure of rank r admits a slight extension to the case where E is no longer a vector bundle but a *projective* vector bundle, i.e. a locally defined vector bundle associated to some G -principal bundle via a projective representation $\rho : G \rightarrow \text{PSO}(r) = \text{SO}(r)/\{\pm I_r\}$. Since the extension of the standard representation of $\text{SO}(r)$ from \mathbb{R}^r to $\Lambda^2 \mathbb{R}^r$ factors through $\text{PSO}(r)$, we see that the second exterior power of any projective vector bundle is a well-defined vector bundle, so Definition 3.3 can be adapted to this setting and the corresponding structure will be referred to as *projective even Clifford structure* in the sequel.

We have proved the following:

Theorem 3.5. *Assume that the curvature constancy of Z is the vertical distribution of a Riemannian submersion $(Z^{k+n}, g_Z) \rightarrow (M^n, g)$. Then (M, g)*

- (a) *carries a parallel even Clifford structure (E, ∇^E, φ) of rank $r = k + 1$;*
- (b) *the curvature of E , viewed as an endomorphism $\omega : \Lambda^2(TM) \rightarrow \text{End}^-(E)$, equals minus twice the metric adjoint of $\varphi : \Lambda^2 E \simeq \text{End}^-(E) \rightarrow \text{End}^-(TM) \simeq \Lambda^2(TM)$.*

Conversely, if (M, g) satisfies these conditions, then the sphere bundle Z of E , together with the Riemannian metric induced by the connection ∇^E on Z defines a Riemannian submersion onto (M, g) whose vertical distribution belongs to the curvature constancy.

We will now leave (momentarily) the notion of curvature constancy, and study in more detail complete simply connected manifolds which admit parallel even Clifford structures. After giving their complete classification we apply it to our original question, and in the last section we also study the related notion of a Clifford structure.

4. EVEN CLIFFORD STRUCTURES

In this section we will classify complete simply connected Riemannian manifolds (M, g) which carry parallel even Clifford structures as introduced in Definition 3.3, in the extended sense of Remark 3.4.

We start by examining even Clifford structures of low rank.

Example 4.1. A rank 2 even Clifford structure induces an almost Hermitian structure on (M, g) (the image by φ of the volume element of $\Lambda^2 E$). Conversely, every almost Hermitian structure J on (M, g) induces a rank 2 even Clifford structure by taking E to be an arbitrary rank 2 Euclidean bundle. The even Clifford structure is parallel if and only if J is a Kähler structure on M .

Example 4.2. A rank 3 even Clifford structure induces a quaternionic structure on (M, g) i.e. a rank 3 sub-bundle S of $\text{End}(TM)$ locally spanned by three almost Hermitian structures satisfying the quaternion relations. If $\{e_1, e_2, e_3\}$ is a local orthonormal basis of E , S is spanned by $I := \varphi(e_1 \cdot e_2)$, $J := \varphi(e_2 \cdot e_3)$ and $K := \varphi(e_3 \cdot e_1)$. Conversely, every quaternionic structure S on (M, g) induces a rank 3 even Clifford structure by taking $E = S$ with the induced Euclidean structure and defining φ as the Hodge isomorphism $\Lambda^2 E \simeq E = S$. By this correspondence, a parallel even Clifford structure is equivalent to a quaternion-Kähler structure on M .

Note that the quaternion-Kähler condition is empty in dimension 4. There are several ways to see this, e.g. by saying that $\text{Sp}(1) \cdot \text{Sp}(1) = \text{SO}(4)$ so there is no holonomy restriction. In our setting, this corresponds to the fact that the bundle $E := \Lambda_+^2 M$ of self-dual 2-forms canonically defines a rank 3 parallel even Clifford structure on every 4-dimensional (oriented) Riemannian manifold.

In general, the representation of $\text{Cl}^0(E)$ on TM cannot be extended to a representation of the whole Clifford bundle $\text{Cl}(E)$ if $r = \text{rk}(E) \neq 3$. On the contrary, this always happens for $r = 3$ because in this case the Hodge isomorphism $E \simeq \Lambda^2 E$ extends to an algebra morphism $\text{Cl}(E) \rightarrow \text{Cl}^0(E)$.

We thus see that Kähler and quaternion-Kähler geometries fit naturally in the more general framework of parallel even Clifford structures.

The fact that the Lie algebra $\mathfrak{so}(4)$ is not simple reduces the case $r = 4$ to $r = 3$ (see Proposition 4.6 (i) below).

Let us now make the following:

Definition 4.3. A parallel even Clifford structure (M, E, ∇^E) is called *flat* if the connection ∇^E is flat.

Theorem 4.4. *A complete simply connected Riemannian manifold (M^n, g) carrying a flat even Clifford structure E of rank $r \geq 5$ is flat, (and thus isometric with a Cl_r^0 representation space).*

Proof. One can choose a parallel global orthonormal frame $\{e_i\}, i = 1, \dots, r$, on E , which induces global parallel complex structures $J_{ij} := \varphi(e_i \cdot e_j)$ on M for every $i < j$.

We claim that if M is irreducible, then it is flat. Since M is hyperkähler with respect to the triple J_{12}, J_{31}, J_{23} , it has to be Ricci-flat. According to the Berger-Simons holonomy theorem, M is either symmetric (hence flat, since a symmetric Ricci-flat manifold is flat), or has holonomy $\text{SU}(n/2), \text{Sp}(n/4)$ or $\text{Spin}(7)$. The last three cases actually do not occur. Indeed, the space of parallel 2-forms on M corresponds to the fixed points of the holonomy

representation on $\Lambda^2\mathbb{R}^n$, or equivalently to the centralizer of the holonomy Lie algebra $\mathfrak{hol}(M)$ in $\mathfrak{so}(n)$. This centralizer is zero for $\text{Hol}(M) = \text{Spin}(7)$, 1-dimensional for $\text{Hol}(M) = \text{SU}(n/2)$ and 3-dimensional $\text{Hol}(M) = \text{Sp}(n/4)$. On the other hand, the space of parallel 2-forms on M has dimension at least $r - 1 \geq 4$ (any two of J_{1i} , $1 < i \leq r$ anti-commute so they are linearly independent), a contradiction which proves our claim.

Back to the general case, the de Rham decomposition theorem states that M is a Riemannian product $M = M_0 \times M_1 \times \dots \times M_k$, where M_0 is flat, and each M_i , $i \geq 1$ is irreducible, non-flat. It is well-known that a parallel complex structure J on a Riemannian manifold (M, g) preserves the tangent bundle of every irreducible non-flat factor of M . Indeed, if M_1 is such a factor, then $J(TM_1) \cap TM_1$ is a parallel sub-bundle of TM_1 , so either $J(TM_1) = TM_1$ or $g(JX, Y) = 0$ for all $X, Y \in TM_1$. But the latter case is impossible since otherwise the Bianchi identity would imply

$$R(X, Y, X, Y) = R(X, Y, JX, JY) = R(X, JX, Y, JY) + R(JX, Y, X, JY) = 0$$

for all $X, Y \in TM_1$, so M_1 would be flat.

Consequently, each non-flat irreducible factor in the de Rham decomposition of M is preserved by every J_{ij} , and thus inherits a flat even Clifford structure of rank r . The first part of the proof shows that no such factor exists, so $M = M_0$ is flat. \square

We continue with an easy algebraic result.

Lemma 4.5. *Let $\{e_1, \dots, e_r\}$ be a local orthonormal frame on E . The endomorphisms $J_{ij} := \varphi(e_i \cdot e_j)$ (which are skew-symmetric for $i \neq j$) satisfy*

$$(23) \quad \begin{cases} J_{ii} = -\text{id} & \text{for all } 1 \leq i \leq r, \\ J_{ij} = -J_{ji} \text{ and } J_{ij}^2 = -\text{id} & \text{for all } i \neq j, \\ J_{ij} \circ J_{ik} = J_{jk} & \text{for all } i, j, k \text{ mutually distinct,} \\ J_{ij} \circ J_{kl} = J_{kl} \circ J_{ij} & \text{for all } i, j, k, l \text{ mutually distinct.} \end{cases}$$

Moreover, if $r \neq 4$, then

$$(24) \quad \langle J_{ij}, J_{kl} \rangle = 0, \quad \text{unless } i = j, k = l \text{ or } i = k \neq j = l \text{ or } i = l \neq k = j.$$

Proof. The first statements follow directly from the usual relations in the Clifford algebra

$$\begin{cases} e_i \cdot e_j = -e_j \cdot e_i & \text{for all } i \neq j, \\ (e_i \cdot e_j)^2 = -\text{id} & \text{for all } i \neq j, \\ (e_i \cdot e_j) \cdot (e_i \cdot e_k) = (e_j \cdot e_k) & \text{for all } i, j, k \text{ mutually distinct,} \\ (e_i \cdot e_j) \cdot (e_k \cdot e_l) = (e_k \cdot e_l) \cdot (e_i \cdot e_j) & \text{for all } i, j, k, l \text{ mutually distinct.} \end{cases}$$

The orthogonality of J_{ij} and J_{kl} is obvious when exactly two of the subscripts coincide (since the corresponding endomorphisms anti-commute). For $r = 3$, (24) is thus satisfied. Assume now that $r \geq 5$ and that all four subscripts are mutually distinct. We then choose s different from i, j, k, l and write, using the fact that J_{sl} and J_{ij} commute:

$$\begin{aligned} \langle J_{ij}, J_{kl} \rangle &= \text{tr}(J_{ij}J_{kl}) = \text{tr}(J_{ij}J_{sk}J_{sl}) = \text{tr}(J_{sl}J_{ij}J_{sk}) \\ &= \text{tr}(J_{ij}J_{sl}J_{sk}) = \text{tr}(J_{ij}J_{lk}) = -\langle J_{ij}, J_{kl} \rangle. \end{aligned}$$

□

The next result is crucial for the classification of parallel even Clifford structures.

Proposition 4.6. *Assume that the complete simply connected Riemannian manifold (M^n, g) carries a parallel non-flat even Clifford structure (E, ∇^E) of rank $r \geq 3$.*

- (i) *If $r = 4$ then (M, g) is a Riemannian product of two quaternion-Kähler manifolds.*
- (ii) *If $r \neq 4$ and $n \neq 8$ then*
 - (a) *The curvature of ∇^E , viewed as a map from $\Lambda^2 M$ to $\text{End}^-(E) \simeq \Lambda^2 E$ is a non-zero constant times the metric adjoint of the Clifford map φ .*
 - (b) *M is Einstein with non-vanishing scalar curvature and has irreducible holonomy.*
- (iii) *If $r \neq 4$ and $n = 8$, then (a) implies (b).*

Proof. Any local orthonormal frame $\{e_1, \dots, e_r\}$ on E induces local endomorphisms on M defined as before by $J_{ij} := \varphi(e_i \cdot e_j)$. We denote by ω_{ij} the curvature forms of the connection ∇^E with respect to the local frame $\{e_i\}$:

$$R_{X,Y}^E e_i = \sum_{j=1}^r \omega_{ji}(X, Y) e_j.$$

From (22) we immediately get $\varphi \circ R_{X,Y}^E = R_{X,Y} \circ \varphi$, where R denotes the Riemannian curvature tensor on (M, g) . Consequently,

$$\begin{aligned} R_{X,Y} J_{ij} &= R_{X,Y} \varphi(e_i \cdot e_j) = \varphi[R_{X,Y}^E(e_i \cdot e_j)] \\ (25) \quad &= \varphi\left[\sum_{s=1}^r \omega_{si}(X, Y) e_s \cdot e_j + e_i \cdot \sum_{s=1}^r \omega_{sj}(X, Y) e_s\right] \\ &= \sum_{s=1}^r [\omega_{si}(X, Y) J_{sj} + \omega_{sj}(X, Y) J_{is}]. \end{aligned}$$

We take $i \neq j$, apply this to some vector Z and take the scalar product with $J_{ij}(W)$ to obtain

$$\begin{aligned} (26) \quad &R(X, Y, J_{ij}(Z), J_{ij}(W)) - R(X, Y, Z, W) = -2\omega_{ij}(X, Y)g(J_{ij}(Z), W) \\ &+ \sum_{s=1}^r [\omega_{si}(X, Y)g(J_{si}(Z), W) + \omega_{sj}(X, Y)g(J_{sj}(Z), W)]. \end{aligned}$$

For $i \neq j$ we define the local two-forms R^{ij} on M by

$$(27) \quad R^{ij}(X, Y) := \sum_{a=1}^n R(J_{ij}X_a, X_a, X, Y),$$

where $\{X_a\}$ denotes a local orthonormal frame on M . In other words, R^{ij} is twice the image of the 2-form J_{ij} via the curvature endomorphism $R : \Lambda^2 M \rightarrow \Lambda^2 M$. The first Bianchi identity easily shows that $R^{ij}(X, Y) = 2 \sum_{a=1}^n R(X, X_a, J_{ij}X_a, Y)$.

(i) Assume that $r = 4$. The image $v := \varphi(\omega)$ of the volume element $\omega := e_1 \cdot e_2 \cdot e_3 \cdot e_4 \in \text{Cl}^0(E)$ is a parallel involution of TM commuting with the $\text{Cl}^0(E)$ -action, so the tangent

bundle of M splits into a parallel direct sum $TM = T^+ \oplus T^-$ of the ± 1 eigen-distributions of v . By the de Rham decomposition theorem, M is a Riemannian product $M = M^+ \times M^-$. The restriction of φ to $\Lambda_{\pm}^2 E$ is trivial on T^{\pm} and defines a rank 3 Clifford structure on M^{\pm} . More explicitly, one can define a local orthonormal frame

$$(28) \quad e_1^{\pm} := \frac{1}{2} \left(e_1 \wedge e_2 \pm e_3 \wedge e_4 \right), \quad e_2^{\pm} := \frac{1}{2} \left(e_1 \wedge e_3 \mp e_2 \wedge e_4 \right), \quad e_3^{\pm} := \frac{1}{2} \left(e_1 \wedge e_4 \pm e_2 \wedge e_3 \right)$$

of $\Lambda_{\pm}^2 E$ and it is clear that the local endomorphisms $J_{ij}^{\pm} := \varphi(e_i^{\pm}) \circ \varphi(e_j^{\pm})$ vanish on M^{\pm} and satisfy the quaternionic relations on M^{\mp} . In fact it is straightforward to check the relations

$$(29) \quad J_{12}^{\pm} = \pm \frac{1}{2} \left(J_{14} \pm J_{23} \right), \quad J_{31}^{\pm} = \pm \frac{1}{2} \left(J_{13} \mp J_{24} \right), \quad J_{23}^{\pm} = \pm \frac{1}{2} \left(J_{12} \pm J_{34} \right)$$

This shows that M is a Riemannian product of two quaternion-Kähler manifolds.

For later use, we remark that the curvature forms ω_{ij}^{\pm} , $1 \leq i, j \leq 3$ of the connection on $\Lambda_{\pm}^2 E$ with respect to the local frame $\{e_i^{\pm}\}$ are related to the forms ω_{ij} by

$$(30) \quad \omega_{12}^{\pm} = \pm(\omega_{14} \pm \omega_{23}), \quad \omega_{31}^{\pm} = \pm(\omega_{13} \mp \omega_{24}), \quad \omega_{23}^{\pm} = \pm(\omega_{12} \pm \omega_{34}).$$

(ii) Assume now that $r \neq 4$. Let us choose some k different from i and j . Taking $Z = X_a$, $W = J_{ik}(X_a)$, summing over a in (26) and using (23) yields

$$(31) \quad 2R^{ik} = \sum_{s=1}^r [\omega_{si} \langle J_{si}, J_{ik} \rangle + \omega_{sj} \langle J_{sj}, J_{ik} \rangle] = n\omega_{ik}.$$

Taking now $Y = Z = X_a$ and summing over a in (26) yields

$$\frac{1}{2} R^{ij}(X, J_{ij}W) = \text{Ric}(X, W) + 2\omega_{ij}(X, J_{ij}(W)) - \sum_{s=1}^r [\omega_{si}(X, J_{si}(W)) + \omega_{sj}(X, J_{sj}(W))].$$

We identify 2-forms and endomorphisms on M using g . The previous relation reads

$$-\frac{1}{2} J_{ij} \circ R^{ij} = \text{Ric} - 2J_{ij} \circ \omega_{ij} + \sum_{s=1}^r [J_{si} \circ \omega_{si} + J_{sj} \circ \omega_{sj}],$$

so taking (31) into account we get for every $i \neq j$

$$(32) \quad 0 = \text{Ric} + (n/4 - 2)J_{ij} \circ \omega_{ij} + \sum_{s=1}^r [J_{si} \circ \omega_{si} + J_{sj} \circ \omega_{sj}].$$

It turns out that this system in the unknown endomorphisms $J_{ij} \circ \omega_{ij}$ has a unique solution for $n > 8$. Indeed, if we denote by $S_i := \sum_{s=1}^r J_{si} \circ \omega_{si}$ and sum over j in (32), we get

$$0 = r\text{Ric} + (n/4 - 2)S_i + rS_i + \sum_{j=1}^r S_j,$$

so $S_i = S_j$ for all i, j . From (32) again we see that $J_{ij} \circ \omega_{ij}$ are all equal for $i \neq j$, and thus proportional with Ric:

$$(33) \quad J_{ij} \circ \omega_{ij} = \frac{1}{4 - n/4 - 2r} \text{Ric}, \quad \forall i \neq j.$$

Since the right term is symmetric, the two skew-symmetric endomorphisms from the left term commute, so J_{ij} commutes with Ric for all i, j . This, in turn, implies like in Lemma 4.5 above that

$$(34) \quad \langle \omega_{ij}, J_{kl} \rangle = 0 \text{ unless } i = k \neq j = l \text{ or } i = l \neq k = j.$$

We finally choose k different from i and j , take $X = J_{ik}(X_a)$, $Y = X_a$, sum over a in (26) and use (34) to obtain

$$-J_{ij} \circ R^{ik} \circ J_{ij} - R^{ik} = - \langle \omega_{ki}, J_{ik} \rangle J_{ki}.$$

By (31) this reads

$$n\omega_{ki} = - \langle \omega_{ki}, J_{ik} \rangle J_{ki}$$

and (33) then implies on the first hand that M is Einstein and on the other hand that the Ricci tensor does not vanish, since otherwise ∇^E would be flat.

There exists thus a non-zero constant κ such that

$$(35) \quad \omega_{ij} = \kappa J_{ij}$$

for all $i \neq j$. This is equivalent to the statement (a).

We will now prove (iib) and (iii) simultaneously. From now on n might be equal to 8, but we assume that (a) holds. We can re-express (25) and (33) as

$$(36) \quad R_{X,Y} J_{ij} = \kappa \sum_{s=1}^r [g(J_{si}(X), Y) J_{sj} + g(J_{sj}(X), Y) J_{is}].$$

and

$$(37) \quad \text{Ric} = \kappa(n/4 + 2r - 4).$$

Assume that M were reducible, i.e. that TM is the direct sum of two parallel distributions T_1 and T_2 . For all $X \in T_1$ and $Y \in T_2$ we have $R_{X,Y} = 0$, so (36) implies

$$0 = \kappa \sum_{s=1}^r [g(J_{si}(X), Y) J_{sj} + g(J_{sj}(X), Y) J_{is}].$$

Taking the scalar product with J_{ik} for some $k \neq i, j$ and using (34) yields

$$0 = g(J_{kj}(X), Y).$$

This shows that each J_{kj} , and hence the whole even Clifford structure, preserves the splitting $TM = T_1 \oplus T_2$. In other words, each integral leaf M_i of T_i ($i = 1, 2$) carries a parallel even Clifford structure. Notice that the relations $\omega_{ij} = \kappa J_{ij}$ for all $i \neq j$ continue to hold on M_1 and M_2 . Formula (32) then shows that the Ricci tensor of each factor T_i must satisfy $\text{Ric}^{T_i} = \kappa(\dim(T_i)/4 + 2r - 4)$, which of course contradicts (37). This finishes the proof of (iib) and (iii). \square

In order to proceed we need the following algebraic interpretation:

Proposition 4.7. *Let (M^n, g) be a simply connected Riemannian manifold with holonomy group $H := \text{Hol}(M)$ acting on \mathbb{R}^n . A parallel rank r ($3 \leq r \neq 4$) even Clifford structure on M is equivalent to an orthogonal representation $\rho : H \rightarrow \text{SO}(r)$ of H on \mathbb{R}^r together with a H -equivariant algebra morphism $\phi : \text{Cl}_r^0 \rightarrow \text{End}(\mathbb{R}^n)$ mapping $\mathfrak{so}(r) \subset \text{Cl}_r^0$ into $\mathfrak{so}(n) \subset \text{End}(\mathbb{R}^n)$.*

Proof. Assume that ρ and ϕ satisfy the conditions above. Let P be the holonomy bundle of (M, g) through some orthonormal frame u_0 , with structure group H . The Levi-Civita connection of M restricts to P and induces a connection on the Euclidean bundle $E := P \times_\rho \mathbb{R}^r$. The bundle morphism

$$\varphi : \text{Cl}^0(E) \rightarrow \text{End}(TM), \quad [u, a] \mapsto [u, \phi(a)]$$

is well-defined since ϕ is H -equivariant and clearly induces a parallel rank r even Clifford structure on (M, g) .

Conversely, if (E, ∇^E) defines a parallel even Clifford structure on M , we claim that E is associated to the holonomy bundle P through u_0 and that ∇^E corresponds to the Levi-Civita connection. Let x_0 be the base point of u_0 , let Γ be the based loop space at x_0 and let Γ_0 be the kernel of the holonomy morphism $\Gamma \rightarrow H$. The parallel transport with respect to ∇^E of E_{x_0} along curves in Γ defines a group morphism $\tilde{\rho} : \Gamma \rightarrow \text{SO}(E_{x_0})$. If $\gamma \in \Gamma_0$, the fact that (E, ∇^E) is a parallel even Clifford structure is equivalent to $\varphi(\Lambda^2(\tilde{\rho}(\gamma))(\omega)) = \varphi(\omega)$ for all $\omega \in \Lambda^2(E)$. Since $\mathfrak{so}(r)$ is simple for $3 \leq r \neq 4$, the map φ is injective. The relation above reduces to $\Lambda^2(\tilde{\rho}(\gamma)) = \text{id}$, thus to $\tilde{\rho}(\gamma) = \text{id}$. This shows that $\Gamma_0 = \text{Ker}(\tilde{\rho})$, so by taking the quotient, $\tilde{\rho}$ defines a faithful orthogonal representation ρ of $H = \Gamma/\Gamma_0$ on E_{x_0} . It is easy to check that the map $P \times_\rho E_{x_0} \rightarrow E$ given by

$$[u, e] \mapsto \tau_\gamma^E(e),$$

where γ is any curve in M whose horizontal lift to P through u_0 ends at u and τ_γ^E denotes the parallel transport on E with respect to ∇^E along γ , is a well-defined bundle morphism preserving the covariant derivatives. The existence of the H -equivariant algebra morphism $\phi : \text{Cl}_r^0 \rightarrow \text{End}(\mathbb{R}^n)$ mapping $\mathfrak{so}(r) \subset \text{Cl}_r^0$ into $\mathfrak{so}(n) \subset \text{End}(\mathbb{R}^n)$ is now straightforward. \square

It is easy to check that this result holds *verbatim* for projective even Clifford structures, by replacing orthogonal representations with projective ones. Notice that if $\rho : H \rightarrow \text{PSO}(r)$ is a projective representation, $\Lambda^2 \rho$ is a linear representation, so the vector bundle $\Lambda^2 E := P \times_{\Lambda^2 \rho} \Lambda^2(\mathbb{R}^r)$ is globally defined, even though $E := P \times_\rho \mathbb{R}^r$ is only locally defined.

Corollary 4.8. *Assume that (M^n, g) satisfies the hypotheses of Proposition 4.6. Then the Lie algebra \mathfrak{h} of the holonomy group H (associated to some holonomy bundle P) is a direct sum of Lie sub-algebras, one of which is isomorphic to $\mathfrak{so}(r)$.*

Proof. Every orthonormal frame $u_0 \in P$ over $x_0 \in M$, defines a natural Lie algebra isomorphism from $\mathfrak{so}(n)$ to $\Lambda^2 M_{x_0}$. In this way, the holonomy algebra \mathfrak{h} is naturally identified with a sub-algebra of $\Lambda^2 M_{x_0}$ and the image \mathfrak{k} of $\mathfrak{so}(r)$ through the map ϕ defined in Proposition 4.7 is naturally identified with $\varphi(\Lambda^2 E_{x_0})$.

The Ambrose-Singer Theorem ([14], Thm. 8.1 Ch.II) shows that \mathfrak{h} contains the image of $\Lambda^2 M_{x_0}$ through the curvature endomorphism. With the notation (27), we thus get $(R^{ij})_{x_0} \in \mathfrak{h}$ for all $1 \leq i, j \leq r$. Taking (31) and (35) into account shows that $\mathfrak{k} \subset \mathfrak{h}$.

Moreover, by Proposition 4.7, \mathfrak{k} is an ideal of \mathfrak{h} . Since \mathfrak{h} is the Lie algebra of a compact Lie group, we immediately obtain the Lie algebra decomposition $\mathfrak{h} = \mathfrak{k} \oplus \mathfrak{k}^\perp$, where \mathfrak{k}^\perp is the orthogonal complement of \mathfrak{k} in \mathfrak{h} with respect to any $\text{ad}_{\mathfrak{h}}$ -invariant metric on \mathfrak{h} . \square

We are now ready for the main result of this section.

Theorem 4.9. *A Riemannian manifold (M^n, g) carrying a parallel non-flat even Clifford structure (E, ∇^E) of rank $r \geq 5$ is either locally symmetric or 8-dimensional.*

Proof. Assume that M is not locally symmetric. According to Proposition 4.6, M has irreducible holonomy and non-vanishing scalar curvature. The Berger-Simons Holonomy Theorem implies that there are exactly three possibilities for the holonomy group H of M : $H = \text{SO}(n)$, $H = \text{U}(n/2)$ or $H = \text{Sp}(n/4) \cdot \text{Sp}(1)$. The second exterior power of the holonomy representation is of course irreducible in the first case and decomposes as

$$\mathfrak{so}(n) = \mathfrak{su}(n/2) \oplus \mathbb{R} \oplus \mathfrak{p}_1,$$

$$\mathfrak{so}(n) = \mathfrak{sp}(n/4) \oplus \mathfrak{sp}(1) \oplus \mathfrak{p}_2$$

in the last two cases. A summand isomorphic to some $\mathfrak{so}(r)$ ($r \geq 5$) occurs in the above decompositions if and only if $r = n$ in the first case, or is obtained from the low-dimensional isomorphisms

$$\mathfrak{su}(n/2) \simeq \mathfrak{so}(r) \quad \text{for } n = 8 \text{ and } r = 6,$$

$$\mathfrak{sp}(n/4) \simeq \mathfrak{so}(r) \quad \text{for } n = 8 \text{ and } r = 5.$$

In the latter cases one has $n = 8$, so we are left with the case when M has generic holonomy $\text{SO}(n)$. By Proposition 4.7, \mathbb{R}^n inherits a Cl_n^0 -module structure, which for dimensional reasons may only occur when $n = 8$. \square

Using this result we will now obtain the classification of complete simply connected manifolds with parallel rank r even Clifford structures. From the above discussion it is enough to consider the cases when $r \geq 5$ and either $\dim(M) = 8$ or M is symmetric.

Case 1. $\dim(M) = 8$. Proposition 4.7 has several consequences:

- (a) \mathbb{R}^8 is a Cl_r^0 representation, thus $5 \leq r \leq 8$.
- (b) The inclusion $\phi : \mathfrak{so}(r) \rightarrow \mathfrak{so}(8)$ is defined by the spin (or half-spin for $r = 8$) representation.
- (c) The holonomy group H is contained in the connected component of the identity $N_{\text{SO}(8)}^0 \mathfrak{so}(r)$ of the normalizer of $\mathfrak{so}(r)$ in $\text{SO}(8)$, acting on its Lie algebra by the adjoint representation.

Using again the low-dimensional isomorphisms $\mathfrak{so}(5) \simeq \mathfrak{sp}(2)$ and $\mathfrak{so}(6) \simeq \mathfrak{su}(4)$ we easily get

$$N_{\text{SO}(8)}^0 \mathfrak{so}(5) = \text{Sp}(2) \cdot \text{Sp}(1), \quad N_{\text{SO}(8)}^0 \mathfrak{so}(6) = \text{U}(4), \quad N_{\text{SO}(8)}^0 \mathfrak{so}(7) = \text{Spin}(7),$$

so a necessary condition for a simply connected 8-dimensional manifold to carry a parallel even Clifford structure of rank r is that M is quaternion-Kähler for $r = 5$, Kähler for $r = 6$ and has holonomy contained in $\text{Spin}(7)$ for $r = 7$ (no condition at all for $r = 8$). Conversely, if M satisfies one of these conditions for $r = 5, 6, 7$ or is an arbitrary manifold in the case $r = 8$, we define E to be associated to the holonomy bundle of M with respect to the following representations of the holonomy group:

- $r = 5$: $\text{Sp}(2) \cdot \text{Sp}(1) \rightarrow \text{SO}(5)$, $a \cdot b \mapsto \xi(a)$, where $\xi : \text{Sp}(2) \simeq \text{Spin}(5) \rightarrow \text{SO}(5)$ is the spin covering.
- $r = 6$: $\text{U}(4) \rightarrow \text{PSO}(6)$ induced by taking the \mathbb{Z}_4 quotient in the projection onto the first factor in $\text{SU}(4) \times \text{U}(1) \rightarrow \text{SU}(4) \simeq \text{Spin}(5)$.
- $r = 7$: The spin covering $\text{Spin}(7) \rightarrow \text{SO}(7)$.
- $r = 8$: One of the two representations $\text{SO}(8) \rightarrow \text{PSO}(8)$ obtained by taking the \mathbb{Z}_2 quotient in the half-spin representations $\text{Spin}(8) \rightarrow \text{SO}(\Delta_{\pm})$.

Notice that for $r = 6$ and $r = 8$ the defining representation of E is projective, so E is only locally defined if M is non-spin. On the contrary, if M is spin then E is a well-defined vector bundle, associated to the spin holonomy bundle of M .

The attentive reader might have noticed the subtlety of the case $r = 8$. In all other cases the equivariant Lie algebra morphism ϕ is constructed by identifying $\mathfrak{so}(r)$ with a factor of the Lie algebra of the holonomy group acting on \mathbb{R}^8 by the *spin* representation (therefore extending to a representation of the even Clifford algebra). For $r = 8$ however, the holonomy representation is *not* the spin representation. What still makes things work in this case is the *triality* of the $\mathfrak{so}(8)$ representations, which is an outer automorphism of $\text{Spin}(8)$ interchanging its three non-equivalent representations on \mathbb{R}^8 . In this way, on a 8-dimensional spin manifold one has six Clifford actions: The Clifford bundle of TM acts on the half spinor bundles $\Sigma_{\pm}M$, $\text{Cl}^0(\Sigma_+M)$ acts on TM and Σ_-M , and $\text{Cl}^0(\Sigma_-M)$ acts on TM and Σ_+M . Of course, when M is not spin, among the six Clifford actions above, only the third and the fifth ones are globally defined.

According to Proposition 4.7, the argument above can be expressed as follows: We denote by $\xi : \text{Spin}(8) \rightarrow \text{SO}(8)$ the spin covering and by $\delta^{\pm} : \text{Spin}(8) \rightarrow \text{SO}(8)$ the half-spin representations. If $H \subset \text{SO}(8)$ is the holonomy group of M , let $\rho : H \rightarrow \text{PSO}(8)$ denote the restriction to H of the \mathbb{Z}_2 -quotient of δ^+ . The isomorphism $\phi : \mathfrak{so}(8) \rightarrow \mathfrak{so}(8)$, $\phi = \xi_* \circ (\delta_*^+)^{-1}$ is tautologically equivariant with respect to the induced representations of H on the two members by ρ and ξ respectively, and it extends to a Clifford action due to triality.

Case 2. $M = G/H$ is symmetric. According to Proposition 4.7, there are two necessary conditions for M to carry a parallel even Clifford structure of rank $r \geq 5$:

- (a) $\mathfrak{so}(r)$ occurs as a summand in the Lie algebra \mathfrak{h} of the isotropy group H .
- (b) The dimension of M has to be a multiple of the dimension $N_0(r)$ of the irreducible Cl_r^0 representation.

Notice that Proposition 4.7 shows that if $M = G/H$ is a compact symmetric space solution of our problem, its non-compact dual G^*/H is solution too, since the isotropy representations are the same. We will thus investigate only the symmetric spaces of compact type.

After a cross-check in the tables of symmetric spaces of Type I and II ([5], pp. 312-317) we are left with the following cases:

(1) $G = \mathrm{SU}(n)$, $H = \mathrm{SO}(n)$. Condition (a) is verified for $r = n$ but it is easy to check that $\dim(M) = (r - 1)(r + 2)/2$ can not be a multiple of $N_0(r)$.

(2) $G = \mathrm{SU}(2n)$, $H = \mathrm{Sp}(n)$. Condition (a) is verified for $n = 2$ and $r = 5$, but $\dim(M) = 5$ is not a multiple of $N_0(5) = 8$.

(3) $G = \mathrm{SU}(p + q)$, $H = S(\mathrm{U}(p) \times \mathrm{U}(q))$. Both conditions are verified for $p = 4$, $r = 6$ and arbitrary q .

(4) $G = \mathrm{SO}(p + q)$, $H = \mathrm{SO}(p) \times \mathrm{SO}(q)$. By condition (a) one can assume $r = p \geq 5$. The isotropy representation is the tensor product \mathbb{R}^{pq} of the standard representations of $\mathrm{SO}(p)$ and $\mathrm{SO}(q)$. Assume that $p \neq 8$. It is well-known that the group $\mathrm{SO}(p)$ has exactly one non-trivial representation on \mathbb{R}^p . This is due to the fact that $\mathrm{SO}(p)$ has no outer automorphisms for p odd, while for p even the only outer automorphisms are the conjugations by matrices in $\mathrm{O}(p) \setminus \mathrm{SO}(p)$. Restricting our attention to the subgroup $\mathrm{SO}(p)$ of the holonomy group H , the map ϕ given by Proposition 4.7 defines a $\mathrm{SO}(p)$ -equivariant representation of $\mathfrak{so}(p)$ on $\mathbb{R}^p \oplus \dots \oplus \mathbb{R}^p$ (q times) and is thus defined by q^2 equivariant components $\phi_{ij} : \mathfrak{so}(p) \rightarrow \mathrm{End}(\mathbb{R}^p)$. It is easy to see that each ϕ_{ij} is then scalar: $\phi_{ij}(A) = \lambda_{ij}A$ for all $A \in \mathfrak{so}(p)$. Finally, the fact that ϕ extends to the Clifford algebra implies that $\phi(A)^2 = -\mathrm{id}$ for $A = \xi_*(e_1 \cdot e_2)$ (here ξ denotes the spin covering $\mathrm{Spin}(p) \rightarrow \mathrm{SO}(p)$), and this is impossible since

$$(\phi(A)^2)_{ij} = \sum_{k=1}^q \lambda_{ik} \lambda_{kj} A^2,$$

and A^2 is not a multiple of the identity. Thus $r = p = 8$ is the only admissible case.

(5) $G = \mathrm{SO}(2n)$, $H = \mathrm{U}(n)$. Condition (a) is verified for $n = 4$ and $r = 6$, but $\dim(M) = 12$ is not a multiple of $N_0(6) = 8$.

(6) $G = \mathrm{Sp}(n)$, $H = \mathrm{U}(n)$. Condition (a) is verified for $n = 4$ and $r = 6$, but $\dim(M) = 20$ is not a multiple of $N_0(6) = 8$.

(7) $G = \mathrm{Sp}(p + q)$, $H = \mathrm{Sp}(p) \times \mathrm{Sp}(q)$. Both conditions are verified for $p = 2$, $r = 5$ and arbitrary q .

(8) If G is one of the exceptional simple Lie groups F_4 , E_6 , E_7 , E_8 , both conditions are simultaneously verified for $H = \mathrm{Spin}(9)$, $\mathrm{Spin}(10) \times \mathrm{U}(1)$, $\mathrm{Spin}(12) \times \mathrm{SU}(2)$ and $\mathrm{Spin}(16)$ respectively. The corresponding symmetric spaces are exactly Rosenfeld's elliptic projective planes $\mathbb{O}\mathbb{P}^2$, $(\mathbb{C} \otimes \mathbb{O})\mathbb{P}^2$, $(\mathbb{H} \otimes \mathbb{O})\mathbb{P}^2$ and $(\mathbb{O} \otimes \mathbb{O})\mathbb{P}^2$.

(9) Finally, no symmetric space of type II (i.e. $M = H \times H/H$) can occur: condition (a) is satisfied for $H = \mathrm{SU}(4)$, $r = 6$ and $H = \mathrm{SO}(n)$, $r = n$ but the dimension of M is 15 in the first case and $n(n - 1)/2$ in the second case, so condition (b) does not hold.

The only candidates of symmetric spaces carrying parallel even Clifford structures of rank $r \geq 5$ are thus those from cases (3), (4), (7) and (8). Conversely, all these spaces carry a (projective) parallel even Clifford structure. This is due to the fact that the restriction of the infinitesimal isotropy representation to the $\mathfrak{so}(r)$ summand is the spin representation in

all cases except for $\mathfrak{so}(8)$, where the triality argument applies. Summarizing, we have proved the following

Theorem 4.10. *The list of complete simply connected Riemannian manifolds M carrying a parallel rank r even Clifford structure is given in the tables below.*

| r | M | dimension of M |
|-----------|--------------------------------------|--|
| 2 | Kähler | $2m, m \geq 1$ |
| 3 | hyperkähler | $4q, q \geq 1$ |
| 4 | reducible hyperkähler | $4(q_1 + q_2), q_1 \geq 1, q_2 \geq 0$ |
| arbitrary | Cl_r^0 representation space | multiple of $N_0(r)$ |

Table 1. Manifolds with flat even Clifford structure

| r | type of E | M | dimension of M |
|-----|----------------------------|---|------------------|
| 2 | | Kähler | $2m, m \geq 1$ |
| 3 | | quaternion-Kähler (QK) | $4q, q \geq 1$ |
| 4 | projective | product of two QK manifolds | $4q, q \geq 1$ |
| 5 | | QK | 8 |
| 6 | projective if M non-spin | Kähler | 8 |
| 7 | | $\text{Spin}(7)$ holonomy | 8 |
| 8 | projective if M non-spin | Riemannian | 8 |
| 5 | | $\text{Sp}(k+2)/\text{Sp}(k) \times \text{Sp}(2)$ | $8k, k \geq 2$ |
| 6 | projective | $\text{SU}(k+4)/\text{S}(\text{U}(k) \times \text{U}(4))$ | $8k, k \geq 2$ |
| 8 | projective if k odd | $\text{SO}(k+8)/\text{SO}(k) \times \text{SO}(8)$ | $8k, k \geq 2$ |
| 9 | | $\mathbb{O}\mathbb{P}^2 = \text{F}_4/\text{Spin}(9)$ | 16 |
| 10 | | $(\mathbb{C} \otimes \mathbb{O})\mathbb{P}^2 = \text{E}_6/\text{Spin}(10) \cdot \text{U}(1)$ | 32 |
| 12 | | $(\mathbb{H} \otimes \mathbb{O})\mathbb{P}^2 = \text{E}_7/\text{Spin}(12) \cdot \text{SU}(2)$ | 64 |
| 16 | | $(\mathbb{O} \otimes \mathbb{O})\mathbb{P}^2 = \text{E}_8/\text{Spin}(16)$ | 128 |

Table 2. Manifolds with parallel non-flat even Clifford structure ¹

5. THE CLASSIFICATION

From Theorem 3.5, every Riemannian submersion $(Z^{k+n}, g_Z) \rightarrow (M^n, g)$ whose vertical distribution belongs to the curvature constancy defines a parallel even Clifford structure $(E, \nabla^E, h, \varphi)$ of rank $r := k + 1$ on M , such that the curvature ω of ∇^E , viewed as an endomorphism $\omega : \Lambda^2(TM) \rightarrow \text{End}^-(E)$, equals minus twice the metric adjoint of the Clifford morphism $\varphi : \Lambda^2 E \rightarrow \text{End}^-(TM)$. In the notation of Proposition 4.6, this amounts to say

¹In this table we adopt the convention that the QK condition is empty in dimension 4. For the sake of simplicity we have omitted the non-compact duals of the symmetric spaces in Table 2. The meticulous reader should add the spaces obtained by replacing $\text{Sp}(k+8)$, $\text{SU}(k+4)$, $\text{SO}(k+8)$, F_4 , E_6 , E_7 and E_8 in the last seven rows with $\text{Sp}(k, 8)$, $\text{SU}(k, 4)$, $\text{SO}_0(k, 8)$, F_4^{-20} , E_6^{-14} , E_7^{-5} and E_8^8 respectively.

that

$$(38) \quad \omega_{ij} = 2J_{ij}, \quad \forall 1 \leq i \neq j \leq r.$$

Conversely, if $(E, \nabla^E, h, \varphi)$ is a parallel even Clifford structure of rank r on M satisfying (38), E carries a Riemannian metric defined by the metric on M , that of E , and the splitting of the tangent bundle of E given by the connection ∇^E and by Theorem 3.5, the restriction to the unit sphere bundle Z of the projection $E \rightarrow M$ is a Riemannian submersion whose vertical distribution belongs to the curvature constancy.

We will now examine under which circumstances a simply connected complete Riemannian manifold

- (i) carries a parallel even Clifford structure $(E, \nabla^E, h, \varphi)$.
- (ii) $(E, \nabla^E, h, \varphi)$ satisfies (38).

Notice that for every $3 \leq n \neq 4$, condition (ii) together with (35) and (37) implies that the scalar curvature of M is

$$(39) \quad \text{scal} = 2n(n/4 + 2r - 4).$$

- $r = 2$. In this case M is Kähler (see Example 4.1) and E is simply a rank 2 Euclidean vector bundle endowed with a metric connection ∇^E whose curvature is minus twice the Kähler form of M . By the Chern-Weil theory, this amounts to say that the cohomology class of the Kähler form is half-integer, so up to rescaling M is a Hodge manifold. It is well-known that the circle bundle Z of E carries a Sasakian structure for the corresponding rescaling of the metric on M .

- $r = 3$. By Example 4.2, condition (i) is equivalent to M being quaternion-Kähler (recall that this is an empty condition for $n = 4$) and E is either $\Lambda_+^2 M$ for $n = 4$ or the 3-dimensional sub-bundle of $\Lambda^2 M$ defining the quaternion-Kähler structure for $n > 4$. Condition (ii) is equivalent to M being anti-self-dual and Einstein with scalar curvature equal to 24 (see [5] p.51 and (39) above) for $n = 4$, and quaternion-Kähler with positive scalar curvature equal to $8q(q + 2)$ for $n = 4q > 4$. The Riemannian manifold (Z, g_Z) is the twistor space of M in the sense of Salamon [17].

- $r = 4$. Proposition 4.6 (i) shows that M is the Riemannian product of two quaternion-Kähler manifolds M^+ and M^- of dimension $4q^+$ and $4q^-$ respectively (notice that one of q^+ or q^- might vanish). Recall that the even Clifford structure E on M induces in a natural way rank 3 even Clifford structures $\Lambda_{\pm}^2 E$ on M^{\mp} . A local orthonormal basis e_i , $1 \leq i \leq 4$ of E induces local orthonormal bases \tilde{e}_i^{\pm} , $1 \leq i \leq 3$ of $\Lambda_{\pm}^2 E$ by (28). Taking (29) and (30) into account, Equation (38) becomes

$$(40) \quad \omega_{ij}^{\pm} = 4J_{ij}^{\pm}, \quad \forall 1 \leq i \neq j \leq 3.$$

Like in the previous case, this means that M^{\pm} is a quaternion-Kähler manifold with scalar curvature $16q^{\pm}(q^{\pm}+2)$, where now we use the usual convention that in dimension 4 quaternion-Kähler means anti-self-dual and Einstein.

In order to describe the Riemannian manifold (Z, g_Z) , we need to understand in more detail the construction of the even Clifford structure of rank 4 on a product of quaternion-Kähler

manifolds $M = M^+ \times M^-$. The orthonormal frame bundle of M admits a reduction to a principal bundle P with structure group $G := \mathrm{Sp}(q^+) \cdot \mathrm{Sp}(1) \times \mathrm{Sp}(q^-) \cdot \mathrm{Sp}(1) \subset \mathrm{SO}(4q^+ + 4q^-)$. The representation of the universal cover of G on $\mathbb{R}^4 \simeq \mathbb{H}$ defined by

$$(A, a, B, b)(v) = avb^{-1} \quad \forall (A, a, B, b) \in \mathrm{Sp}(q^+) \times \mathrm{Sp}(1) \times \mathrm{Sp}(q^-) \times \mathrm{Sp}(1), \forall v \in \mathbb{H}$$

induces a projective representation $\rho : G \rightarrow \mathrm{PSO}(4)$, which in turn determines the (locally defined) bundle E and the (globally defined) manifold $Z := P \times_{\rho} \mathbb{R}\mathbb{P}^3$. A Riemannian manifold obtained in this way is called *quaternion-Sasakian*. By definition, a quaternion-Sasakian manifold fibres over a product of quaternion-Kähler manifolds $M = M^+ \times M^-$, with fiber $\mathbb{R}\mathbb{P}^3$. Notice that 3-Sasakian manifolds are special cases of quaternion-Sasakian manifolds, when one of the factors M^+ or M^- is reduced to a point.

We now examine the remaining cases in Table 2.

- $r \geq 5$ and $n = 8$. Taking (31) into account, (38) is equivalent to the fact that the restriction of the curvature endomorphism R of M to the Lie sub-algebra $\varphi(\Lambda^2 E) \subset \Lambda^2 M$ equals $4\mathrm{id}$. Moreover, we have $\kappa = 2$ in Equation (35), so (36) shows that M is Einstein with scalar curvature $2n(n/4 + 2r - 4)$.

If $r = 8$, this means that R is constant, equal to 4 on $\Lambda^2 M$, so M is the round sphere $\mathbb{S}^8(1/2)$ of radius $1/2$.

The case $r = 7$ does not occur, since a manifold with holonomy $\mathrm{Spin}(7)$ is Ricci-flat, contradicting Proposition 4.6 (iii).

If $r = 6$, M is Kähler and $\varphi(\Lambda^2 E)$ is just the sub-bundle $\Lambda_0^{(1,1)} M$ of primitive forms of type $(1, 1)$, corresponding to the isomorphism $\mathfrak{spin}(6) \simeq \mathfrak{su}(4)$. By the above M has Einstein constant equal to 20. This shows that the curvature endomorphism of M is equal to 4 on $\Lambda_0^{(1,1)} M$, is equal to 20 on the line generated by the Kähler form (since the image of the Kähler form is the Ricci form), and vanishes on $\Lambda^{(2,0)+(0,2)} M$ (like on every Kähler manifold), so M is isometric to the complex projective space $\mathbb{C}\mathbb{P}^4 = \mathrm{SU}(5)/\mathrm{S}(\mathrm{U}(1) \cdot \mathrm{U}(4))$ endowed with the Fubini-Study metric with scalar curvature 160.

If $r = 5$, M is quaternion-Kähler, and by a slight abuse of notation we can write $\Lambda^2 M = \mathfrak{sp}(1) \oplus \mathfrak{sp}(2) \oplus \mathfrak{p}$. Like before, the curvature endomorphism R of M equals 4 on $\mathfrak{sp}(2) = \varphi(\Lambda^2 E)$. Moreover, on every quaternion-Kähler manifold with Einstein constant 16, R equals 4 on $\mathfrak{sp}(1)$ and vanishes on \mathfrak{p} . Thus M is isometric to $\mathbb{H}\mathbb{P}^2 = \mathrm{Sp}(3)/\mathrm{Sp}(1) \times \mathrm{Sp}(2)$.

- $r \geq 5$ and $n > 8$. This case concerns the symmetric spaces M in the last seven rows of Table 2. For each of these spaces condition (ii) is automatically satisfied (by Proposition 4.6) for the specific normalization of the metric for which $\kappa = 2$ in Equation (35), which by (36) is equivalent to the scalar curvature being equal to $2n(n/4 + 2r - 4)$.

Summarizing, we have shown that there exists a Riemannian submersion from a complete Riemannian manifold (Z^{k+n}, g_Z) to a complete simply connected Riemannian manifold (M^n, g) whose vertical distribution belongs to the curvature constancy if and only if (Z, M) belongs to the following list:

| Z | M | Fibre | $\dim(M)$ | $\text{scal}(M)$ |
|--|---|--------------------------|-----------------------------------|---------------------------------------|
| Sasakian | Hodge | \mathbb{S}^1 | $2m, m \geq 1$ | |
| Twistor space Z | quaternion-Kähler (QK) | \mathbb{S}^2 | $4q, q \geq 1$ | $8q(q+2)$ |
| Quaternion-Sasakian | product of two QK manifolds | $\mathbb{R}\mathbb{P}^3$ | $4q, q \geq 1$ $q = q^+ + q^-$ | $16q^+(q^+ + 2)$ $+16q^-(q^- + 2)$ |
| $\frac{\text{Sp}(k+2)}{\text{Sp}(k) \times \text{Spin}(4)}$ | $\text{Sp}(k+2)/\text{Sp}(k) \times \text{Sp}(2)$ | \mathbb{S}^4 | $8k, k \geq 1$ | $32k(k+3)$ |
| $\frac{\text{SU}(k+4)}{\text{S}(\text{U}(k) \times (\text{Sp}(2) \cdot \text{U}(1)))}$ | $\text{SU}(k+4)/\text{S}(\text{U}(k) \times \text{U}(4))$ | $\mathbb{R}\mathbb{P}^5$ | $8k, k \geq 1$ | $32k(k+4)$ |
| $\frac{\text{SO}(k+8)}{\text{SO}(k) \times \text{Spin}(7)}$ | $\text{SO}(k+8)/\text{SO}(k) \times \text{SO}(8)$ | $\mathbb{R}\mathbb{P}^7$ | $8k, k \geq 1$ | $32k(k+6)$ |
| $F_4/\text{Spin}(8)$ | $F_4/\text{Spin}(9)$ | \mathbb{S}^8 | 16 | $2^6 \cdot 3^2$ |
| $E_6/\text{Spin}(9) \cdot \text{U}(1)$ | $E_6/\text{Spin}(10) \cdot \text{U}(1)$ | \mathbb{S}^9 | 32 | $2^9 \cdot 3$ |
| $E_7/\text{Spin}(11) \cdot \text{SU}(2)$ | $E_7/\text{Spin}(12) \cdot \text{SU}(2)$ | \mathbb{S}^{11} | 64 | $2^9 \cdot 3^2$ |
| $E_8/\text{Spin}(15)$ | $E_8/\text{Spin}(16)$ | \mathbb{S}^{15} | 128 | $2^{10} \cdot 3 \cdot 5$ |

Table 3. Riemannian submersions with curvature constancy.²

6. CLIFFORD STRUCTURES

Looking at Definition 3.3 one may wonder under which circumstances the Clifford map $\varphi : \Lambda^2 E \rightarrow \Lambda^2 M \subset \text{End}(TM)$ extends not only to the even Clifford algebra $\text{Cl}^0(E)$, but to the full Clifford algebra bundle of E . This problem has an obvious interest in its own, although it is not directly related to geometric considerations like curvature constancy.

Since the restriction of any Clifford algebra representation to the defining vector space is always faithful, this special case of Definition 3.3 is equivalent to the following

Definition 6.1. A rank r Clifford structure ($r \geq 1$) on (M^n, g) is an oriented rank r subbundle E of $\Lambda^2 M$ together with an algebra bundle morphism $\varphi : \text{Cl}(E) \rightarrow \text{End}(TM)$ such that $\varphi(e) = e$ for all $e \in E \subset \text{Cl}(E)$.

A Clifford structure (M, g, E) is called *parallel* if E is parallel with respect to the Levi-Civita connection ∇^g of (M, g) .

Example 6.2. Every almost Hermitian structure J on (M, g) induces a rank 1 Clifford structure by taking $E = \langle J \rangle$. Conversely, if E is a rank 1 Clifford structure and J denotes the positive unit section of E , then J is a skew-symmetric endomorphism of TM satisfying

$$J \circ J = \varphi(J \cdot J) = \varphi(-1) = -\text{id}_{TM},$$

i.e. J is an almost Hermitian structure. There is thus a one-to-one correspondence between rank 1 Clifford structures and almost Hermitian structures. A rank 1 Clifford structure is parallel if and only if the corresponding almost Hermitian structure is Kähler.

The remaining part of this section is devoted to the proof of the following classification result.

²We adopt in this table the usual convention that QK in dimension 4 means anti-self-dual and Einstein.

Theorem 6.3. *A simply connected Riemannian manifold (M^n, g) carries a parallel rank r Clifford structure if and only if one of the following (non-exclusive) cases occur:*

- $r = 1$ and M is Kähler.
- $r = 2$ and either $n = 4$ and M is Kähler or $n \geq 8$ and M is hyperkähler.
- $r = 3$ and M is quaternion-Kähler.
- $r = 4$, $n = 8$ and M is a product of two Ricci-flat Kähler surfaces.
- $r = 5$, $n = 8$ and M is hyperkähler.
- $r = 6$, $n = 8$ and M is Kähler Ricci-flat.
- $r = 7$ and M is an 8-dimensional manifold with $\text{Spin}(7)$ holonomy.
- r is arbitrary and M is flat, isometric to a nontrivial representation of the Clifford algebra Cl_r .

Proof. Assume that (M^n, g) carries a rank r parallel Clifford structure $E \subset \Lambda^2 M$. The image by $\varphi : \text{Cl}(E) \rightarrow \text{End}(TM)$ of the volume element is a parallel endomorphism v of TM which satisfies $v \circ v = (-1)^{\frac{r(r+1)}{2}}$ and commutes (resp. anti-commutes) with every element of E for r odd (resp. even). We start by considering the cases $r \leq 4$.

- $r = 1$. It was already noticed that a parallel rank 1 Clifford structure corresponds to a Kähler structure on M .
- $r = 2$. The rank 2 Clifford structure E induces a rank 3 Clifford structure $E' := E \oplus \Lambda^2 E$ on M . Explicitly, if $\{e_1, e_2\}$ is a local orthonormal basis of E , then $e_3 := e_1 \circ e_2$ is independent of the chosen basis and $\{e_1, e_2, e_3\}$ satisfy the quaternionic relations. Moreover, $e_3 = v$ is a parallel endomorphism of TM , so (M, g) is Kähler. In the notation of Proposition 4.6 we have $\omega_{13} = \omega_{23} = 0$. Formula (32) yields

$$0 = \text{Ric} + n/4 J_{ij} \circ \omega_{ij} + J_{si} \circ \omega_{si} + J_{sj} \circ \omega_{sj}$$

for every permutation $\{i, j, s\}$ of $\{1, 2, 3\}$. If $n > 4$ this system shows that $\omega_{12} = 0$, so M is hyperkähler. Conversely, if either $n = 4$ and (M, g, J) is Kähler, or $n > 4$ and (M, g, I, J, K) is hyperkähler, then $E = \Lambda^{(2,0)+(0,2)} M$ in the first case, or $E = \langle I, K \rangle$ in the second case, define a rank 2 parallel Clifford structure on M .

- $r = 3$. It was already noticed that because of the isomorphism $\Lambda^2 E \cong E$, every rank 3 even Clifford structure is automatically a Clifford structure, and corresponds to a quaternion-Kähler structure (which, we recall, is an empty condition for $n = 4$).
- $r = 4$. The endomorphism v is now a parallel involution of TM anti-commuting with every element of the Clifford structure $E \subset \Lambda^2 M$. Correspondingly, the tangent bundle of M splits in a parallel direct sum $TM = T^+ \oplus T^-$, such that $v|_{T^\pm} = \pm \text{id}$. If we denote by J_i , $1 \leq i \leq 4$ a local orthonormal basis of E , each J_i maps T^\pm to T^\mp . The de Rham decomposition theorem shows that M is a Riemannian product $M = M^+ \times M^-$ and $TM^\pm = T^\pm$. The Riemannian curvature tensor of M is the sum of the two curvature tensors of M^+ and M^- : $R = R^+ + R^-$. Let ω_{ij} denote the curvature forms (with respect to the local frame $\{J_i\}$) of the Levi-Civita connection on E :

$$R_{X,Y} J_i = \sum_{j=1}^4 \omega_{ji}(X, Y) J_j.$$

We take $X, Y \in T^+$ and apply the previous relation to some $Z \in T^+$ and obtain

$$R_{X,Y}^+ Z = \sum_{j=1}^4 \omega_{ji}(X, Y) J_j J_i Z, \quad \forall 1 \leq i \leq 4.$$

For $1 \leq j \leq 3$ we denote by $\omega_j := \omega_{j4}$ and $I_j := -J_j J_4$. Since by definition $v = J_1 J_2 J_3 J_4$, it is easy to check that I_j are anti-commuting almost complex structures on M^+ satisfying the quaternionic relations $I_1 I_2 = I_3$ etc. The previous curvature relation reads

$$(41) \quad R_{X,Y}^+ = - \sum_{j=1}^3 \omega_j(X, Y) I_j, \quad \forall X, Y \in T^+.$$

The symmetry by pairs of R^+ implies that $\omega_i = \sum_{j=1}^3 a_{ji} I_j$ for some smooth functions a_{ij} satisfying $a_{ij} = a_{ji}$. Moreover, the first Bianchi identity applied to (41) yields

$$(42) \quad \sum_{i,j=1}^3 a_{ij} I_i \wedge I_j = 0.$$

If $\dim(M^+) > 4$, we may choose non-vanishing vectors $X, Y \in T^+$ such that Y is orthogonal to X and to $I_i X$ for $i = 1, 2, 3$. Applying (42) to $X, I_i X, Y, I_j Y$ yields $a_{ij} + a_{ji} = 0$, so $\omega_j = 0$. By (41) we get $R^+ = 0$ and similarly $R^- = 0$, so M is flat. It remains to study the case $\dim(M^+) = 4$. In this case I_1, I_2 and I_3 are a basis of the space of self-dual 2-forms $\Lambda_+^2 M^+$, so (41) is equivalent to the fact that M^+ is self-dual and has vanishing Ricci tensor (see e.g. [5], p.51). In other words, M^+ is Kähler (with respect to any parallel 2-form in $\Lambda_+^2 M^+$) and Ricci-flat, and the same holds of course for M^- .

Conversely, assume that $M = M^+ \times M^-$ is a Riemannian product of two simply connected Ricci-flat Kähler surfaces. The holonomy of M is then a subgroup of $SU(2) \times SU(2) \simeq Spin(4)$, so the frame bundle of M and the Levi-Civita connection reduce to a principal $SU(2) \times SU(2)$ -bundle P . Let ξ denote the representation of $Spin(4)$ on \mathbb{R}^4 coming from the spin covering $Spin(4) \rightarrow SO(4)$ and let ρ denote the representation of $Spin(4)$ on $\mathfrak{so}(8)$ obtained by restricting the adjoint action of $SO(8)$ to $Spin(4) \simeq SU(2) \times SU(2) \subset SO(8)$. The irreducible representation of Cl_4 on \mathbb{R}^8 defines a $Spin(4)$ -equivariant map from \mathbb{R}^4 to $\mathfrak{so}(8)$ (with respect to the above actions of $Spin(4)$). The above map defines an embedding of the rank 4 vector bundle $E := P \times_{\xi} \mathbb{R}^4$ into $\Lambda^2 M = P \times_{\rho} \mathfrak{so}(8)$, which is by construction a parallel Clifford structure on M .

For $r \geq 5$ we will use the fact that E defines tautologically a rank r parallel even Clifford structure on M , and apply Theorems 4.4 and 4.10 to reduce the study to manifolds appearing in Table 2.

- $r = 5$. The volume element v defines a Kähler structure on M in this case. The quaternionic Grassmannians $Sp(k+8)/Sp(k) \cdot Sp(2)$ are obviously not Kähler (since the Lie algebra of the isometry group of every Kähler symmetric space has a non-trivial center), so it remains to examine the case $n = 8$, when, according to Theorem 4.10, M is quaternion-Kähler. More explicitly, if E is the rank 5 vector bundle defining the Clifford structure, $\varphi(\Lambda^2 E)$ is a Lie

sub-algebra of $\Lambda^2 M \simeq \mathfrak{so}(8)$ isomorphic to $\mathfrak{so}(5) \simeq \mathfrak{sp}(2)$ and its centralizer is a Lie sub-algebra \mathfrak{s} of $\Lambda^2 M$ isomorphic to $\mathfrak{so}(3)$, defining a quaternion-Kähler structure. Moreover v belongs to \mathfrak{s} (being the image of a central element in the Clifford algebra of E), so we easily see that its orthogonal complement v^\perp in \mathfrak{s} defines a rank 2 parallel Clifford structure on M . By the case $r = 2$ above, M is then hyperkähler.

Conversely, every 8-dimensional hyperkähler manifold carries parallel Clifford structures of rank 5 obtained as follows. Let ξ denote the representation of $\text{Spin}(5)$ on \mathbb{R}^5 coming from the spin covering $\text{Spin}(5) \rightarrow \text{SO}(5)$ and let ρ denote the representation of $\text{Spin}(5)$ on $\mathfrak{so}(8)$ obtained by restricting the adjoint action of $\text{SO}(8)$ to $\text{Spin}(5) \simeq \text{Sp}(2) \subset \text{SO}(8)$. The irreducible representation of Cl_5 on \mathbb{R}^8 defines a $\text{Spin}(5)$ -equivariant map from \mathbb{R}^5 to $\mathfrak{so}(8)$ (with respect to the above actions of $\text{Spin}(5)$). If P denotes the holonomy bundle of M with structure group $\text{Sp}(2) \simeq \text{Spin}(5)$, the above map defines an embedding of the rank 5 vector bundle $E := P \times_\xi \mathbb{R}^5$ into $\Lambda^2 M = P \times_\rho \mathfrak{so}(8)$, which is by construction a parallel Clifford structure on M .

• $r = 6$. The volume element v is now a Kähler structure anti-commuting with every element of the Clifford structure E . If we denote by J_i , $1 \leq i \leq 6$ a local orthonormal basis of the Clifford structure, each J_i is a 2-form of type $(2, 0) + (0, 2)$ with respect to v , so the curvature endomorphism vanishes on J_i :

$$(43) \quad 0 = R(J_i)(X, Y) = \sum_{a=1}^n R(J_i X_a, X_a, X, Y) = 2 \sum_{a=1}^n R(X, X_a, J_i X_a, Y).$$

Let ω_{ij} denote the curvature forms (with respect to the local frame $\{J_i\}$) of the Levi-Civita connection on E :

$$R_{X,Y} J_i = \sum_{j=1}^6 \omega_{ji}(X, Y) J_j.$$

We can express this as follows:

$$R(X, Y, J_i Z, J_i W) - R(X, Y, Z, W) = \sum_{j=1}^6 \omega_{ji}(X, Y) g(J_j Z, J_i W).$$

Taking the trace in Y and Z and using (43) yields

$$\text{Ric} = - \sum_{j=1}^6 J_j \circ J_i \circ \omega_{ji}.$$

This relation, together with (32), shows that $\text{Ric} = 0$.

Conversely, every 8-dimensional Ricci-flat Kähler manifold carries parallel Clifford structures of rank 6 defined by the $\text{Spin}(6) \simeq \text{SU}(4)$ -equivariant embedding of \mathbb{R}^6 into $\mathfrak{so}(8)$ coming from the irreducible representation of Cl_6 on \mathbb{R}^8 , like in the case $r = 5$.

• $r = 7$. Theorem 4.10 shows that M has to be a 8-dimensional manifold with holonomy $\text{Spin}(7)$. By an argument similar to the previous ones, every such manifold carries parallel Clifford structures of rank 7 defined by the $\text{Spin}(7)$ -equivariant embedding of \mathbb{R}^7 into $\mathfrak{so}(8)$ coming from one of the irreducible representations of Cl_7 on \mathbb{R}^8 .

- $r = 8$. The dimension of M has to be at least equal to 16 in this case (since the dimension of the irreducible Cl_8 -representation is 16). Moreover, the volume element v is a parallel involution of TM anti-commuting with every element of E , so TM splits in a parallel direct sum of the ± 1 eigen-distributions of v . This contradicts Proposition 4.6.
- Finally, for $r \geq 9$, the spaces appearing in the last four rows of Table 2 cannot carry a Clifford structure since the dimension of the irreducible representation of Cl_r for $r = 9, 10, 12, 16$ is 32, 64, 128, 256 respectively, which is exactly twice the dimension of the corresponding tangent spaces in each case. \square

We end up this paper with a short list of interesting problems related to Clifford structures and perspectives of possible further research. These are just a few examples of the numerous questions raised by our work.

- The notion of curvature constancy has a hyperbolic counterpart which leads to the notion of Lorentzian Clifford structures. This problem can be studied with methods similar to those above and could provide a new framework for theoretical physicists.
- Many notions and results from almost Hermitian geometry can be generalized to Clifford structures. One can for instance introduce the minimal connection of an (even) Clifford structure, and obtain a Gray-Hervella-type classification of Clifford structures.
- One can also address the question of the existence of global almost complex structures compatible with a parallel (even) Clifford structure, generalizing corresponding results by D. V. Alekseevsky, S. Marchiafava and M. Pontecorvo [2] obtained for quaternion-Kähler manifolds.
