#### Abstract

This article deals with the numerical resolution of Markovian backward stochastic differential equations (BSDEs) with drivers of quadratic growth with respect to $z$ and bounded terminal conditions. We first show some bound estimates on the process $Z$ and we specify the Zhang's path regularity theorem. Then we give a new time discretization scheme with a non uniform time net for such BSDEs and we obtain an explicit convergence rate for this scheme.

## 1 Introduction

Since the early nineties, there has been an increasing interest for backward stochastic differential equations (BSDEs for short). These equations have a wide range of applications in stochastic control, in finance or in partial differential equation theory. A particular class of BSDE is studied since few years: BSDEs with drivers of quadratic growth with respect to the variable $z$. This class arises, for example, in the context of utility optimization problems with exponential utility functions, or alternatively in questions related to risk minimization for the entropic risk measure (see e.g. [13]). Many papers deal with existence and uniqueness of solution for such BSDEs: we refer the reader to [17, 18] when the terminal condition is bounded and [ $3,7,9]$ for the unbounded case. Our concern is rather related to the simulation of BSDEs and more precisely time discretization of BSDEs coupled with a forward stochastic differential equation (SDE for short). Actually, the design of efficient algorithms which are able to solve BSDEs in any reasonable dimension has been intensively studied since the first work of Chevance [6], see for instance [19, 11, 11]. But in all these works, the driver of the BSDE is a Lipschitz function with respect to $z$ and this assumption plays a key role in theirs proofs. In a recent paper, Cheridito and Stadje [ 5$]$ studied approximation of BSDEs by backward stochastic difference equations which are based on random walks instead of Brownian motions. They obtain a convergence result when the driver has a subquadratic growth with respect to $z$ and they give an example where this approximation does not converge when the driver has a quadratic growth. To the best of our knowledge, the only work where the time approximation of a BSDE with a quadratic growth with respect to $z$ is studied is the one of Imkeller and Reis [14]. Let notice that, when the driver has a specific form $\square$ it is possible to get around the problem by using an exponential transformation method (see [15]) or by using results on fully coupled forward-backward differential equations (see [7]).

[^0]To explain ideas of this paper, let us introduce $(X, Y, Z)$ the solution to the forward backward system

$$
\begin{aligned}
X_{t} & =x+\int_{0}^{t} b\left(s, X_{s}\right) d s+\int_{0}^{t} \sigma(s) d W_{s} \\
Y_{t} & =g\left(X_{T}\right)+\int_{t}^{T} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s-\int_{t}^{T} Z_{s} d W_{s}
\end{aligned}
$$

where $g$ is bounded, $f$ is locally Lipschitz and has a quadratic growth with respect to $z$. A well-known result is that when $g$ is a Lipschitz function with Lipschitz constant $K_{g}$, then the process $Z$ is bounded by $C\left(K_{g}+1\right)$ (see Theorem 3.1). So, in this case, the driver of the BSDE is a Lipschitz function with respect to $z$. Thereby, a simple idea is to do an approximation of $(Y, Z)$ by the solution $\left(Y^{N}, Z^{N}\right)$ to the BSDE

$$
Y_{t}^{N}=g_{N}\left(X_{T}\right)+\int_{t}^{T} f\left(s, X_{s}, Y_{s}^{N}, Z_{s}^{N}\right) d s-\int_{t}^{T} Z_{s}^{N} d W_{s}
$$

where $g_{N}$ is a Lipschitz approximation of $g$. Thanks to bounded mean oscillation martingale (BMO martingale in the sequel) tools, we have an error estimate for this approximation: see e.g. [14, 2] or Proposition 4.2. For example, if $g$ is $\alpha$-Hölder, we are able to obtain the error bound $C K_{g_{N}}^{\frac{-\alpha}{1-\alpha}}$ (see Proposition 4.10). Moreover, we can have an error estimate for the time discretization of the approximated BSDE thanks to any numerical scheme for BSDEs with Lipschitz driver. But, this error estimate depends on $K_{g_{N}}$ : roughly speaking, this error is $C e^{C K_{g_{N}}^{2}} n^{-1}$ with $n$ the number of discretization times. The exponential term results from the use of Gronwall's inequality. Finally, when $g$ is $\alpha$-Hölder and $K_{g_{N}}=N$, the global error bound is

$$
\begin{equation*}
C\left(\frac{1}{N^{\frac{\alpha}{1-\alpha}}}+\frac{e^{C N^{2}}}{n}\right) \tag{1.1}
\end{equation*}
$$

So, when $N$ increases, $n^{-1}$ will have to become small very quickly and the speed of convergence turns out to be bad: if we take $N=\left(\frac{C}{\varepsilon} \log n\right)^{1 / 2}$ with $0<\varepsilon<1$, then the global error bound becomes $C_{\varepsilon}(\log n)^{\frac{-\alpha}{2(1-\alpha)}}$. The same drawback appears in the work of Imkeller and Reis [14]. Indeed, their idea is to do an approximation of $(Y, Z)$ by the solution $\left(Y^{N}, Z^{N}\right)$ to the truncated BSDE

$$
Y_{t}^{N}=g\left(X_{T}\right)+\int_{t}^{T} f\left(s, X_{s}, Y_{s}^{N}, h_{N}\left(Z_{s}^{N}\right)\right) d s-\int_{t}^{T} Z_{s}^{N} d W_{s}
$$

where $h_{N}: \mathbb{R}^{1 \times d} \rightarrow \mathbb{R}^{1 \times d}$ is a smooth modification of the projection on the open Euclidean ball of radius $N$ about 0 . Thanks to several statements concerning the path regularity and stochastic smoothness of the solution processes, the authors show that for any $\beta \geqslant 1$, the approximation error is lower than $C_{\beta} N^{-\beta}$. So, they obtain the global error bound

$$
\begin{equation*}
C_{\beta}\left(\frac{1}{N^{\beta}}+\frac{e^{C N^{2}}}{n}\right) \tag{1.2}
\end{equation*}
$$

and, consequently, the speed of convergence also turns out to be bad: if we take $N=\left(\frac{C}{\varepsilon} \log n\right)^{1 / 2}$ with $0<\varepsilon<1$, then the global error bound becomes $C_{\beta, \varepsilon}(\log n)^{-\beta / 2}$.

Another idea is to use an estimate of $Z$ that does not depends on $K_{g}$. So, we extend a result of [8] which shows

$$
\begin{equation*}
\left|Z_{t}\right| \leqslant M_{1}+\frac{M_{2}}{(T-t)^{1 / 2}}, \quad 0 \leqslant t<T \tag{1.3}
\end{equation*}
$$

Let us notice that this type of estimation is well known in the case of drivers with linear growth as a consequence of the Bismut-Elworthy formula: see e.g. [10]. But in our case, we do not need to suppose that $\sigma$ is invertible. Then, thanks to this estimation, we know that, when $t<T, f(t, ., .,$.$) is a Lipschitz$ function with respect to $z$ and the Lipschitz constant depends on $t$. So we are able to modify the classical uniform time net to obtain a convergence speed for a modified time discretization scheme for our BSDE: the idea is to put more discretization points near the final time $T$ than near 0 . The same idea is used by Gobet and Makhlouf in [12] for BSDEs with drivers of linear growth and a terminal function $g$ not Lipschitz. But due to technical reasons we need to apply this modified time discretization scheme to the approximated BSDE:

$$
Y_{t}^{N, \varepsilon}=g_{N}\left(X_{T}\right)+\int_{t}^{T} f^{\varepsilon}\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right) d s-\int_{t}^{T} Z_{s}^{N, \varepsilon} d W_{s}
$$

with

$$
f^{\varepsilon}(s, x, y, z):=\mathbb{1}_{s<T-\varepsilon} f(s, x, y, z)+\mathbb{1}_{s \geqslant T-\varepsilon} f(s, x, y, 0)
$$

Thanks to the estimate (1.3), we obtain a speed convergence for the time discretization scheme of this approximated BSDE (see Theorem 4.8). Moreover, BMO tools give us again an estimate of the approximation error (see Proposition 4.2). Finally, if we suppose that $g$ is $\alpha$-Hölder, we prove that we can choose properly $N$ and $\varepsilon$ to obtain the global error estimate $C n^{-\frac{2 \alpha}{(2-\alpha)(2+K)-2+2 \alpha}}$ (see Theorem 4.13) where $K>0$ depends on constant $M_{2}$ defined in equation (1.3) and constants related to $f$. Let us notice that such a speed of convergence where constants related to $f, g, b$ and $\sigma$ appear in the power of $n$ is unusual. Even if we have an error far better than (1.1) or (1.2), this result is not very interesting in practice because the speed of convergence strongly depends on $K$. But, when $b$ is bounded, we prove that we can take $M_{2}$ as small as we want in (1.3). Finally, we obtain a global error estimate lower than $C_{\eta} n^{-(\alpha-\eta)}$, for all $\eta>0$ (see Theorem 4.16).

The paper is organized as follows. In the introductory Section 2 we recall some of the well known results concerning SDEs and BSDEs. In Section 3 we establish some estimates concerning the process $Z$ : we show a first uniform bound for $Z$, then a time dependent bound and finally we specify the classical path regularity theorem. In Section 4 we define a modified time discretization scheme for BSDEs with a non uniform time net and we obtain an explicit error bound.

## 2 Preliminaries

### 2.1 Notations

Throughout this paper, $\left(W_{t}\right)_{t \geqslant 0}$ will denote a $d$-dimensional Brownian motion, defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. For $t \geqslant 0$, let $\mathcal{F}_{t}$ denote the $\sigma$-algebra $\sigma\left(W_{s} ; 0 \leqslant s \leqslant t\right)$, augmented with the $\mathbb{P}$-null sets of $\mathcal{F}$. The Euclidian norm on $\mathbb{R}^{d}$ will be denoted by $|$.$| . The operator norm induced by |$.$| on the$ space of linear operator is also denoted by $|$.$| . For p \geqslant 2, m \in \mathbb{N}$, we denote further

- $\mathcal{S}^{p}\left(\mathbb{R}^{m}\right)$, or $\mathcal{S}^{p}$ when no confusion is possible, the space of all adapted processes $\left(Y_{t}\right)_{t \in[0, T]}$ with values in $\mathbb{R}^{m}$ normed by $\|Y\|_{\mathcal{S}^{p}}=\mathbb{E}\left[\left(\sup _{t \in[0, T]}\left|Y_{t}\right|\right)^{p}\right]^{1 / p} ; \mathcal{S}^{\infty}\left(\mathbb{R}^{m}\right)$, or $\mathcal{S}^{\infty}$, the space of bounded measurable processes;
- $\mathcal{M}^{p}\left(\mathbb{R}^{m}\right)$, or $\mathcal{M}^{p}$, the space of all progressively measurable processes $\left(Z_{t}\right)_{t \in[0, T]}$ with values in $\mathbb{R}^{m}$ normed by $\|Z\|_{\mathcal{M}^{p}}=\mathbb{E}\left[\left(\int_{0}^{T}\left|Z_{s}\right|^{2} d s\right)^{p / 2}\right]^{1 / p}$.

In the following, we keep the same notation $C$ for all finite, nonnegative constants that appear in our computations: they may depend on known parameters deriving from assumptions and on $T$, but not on
any of the approximation and discretization parameters. In the same spirit, we keep the same notation $\eta$ for all finite, positive constants that we can take as small as we want independently of the approximation and discretization parameters.

### 2.2 Some results on BMO martingales

In our work, the space of BMO martingales play a key role for the a priori estimates needed in our analysis of BSDEs. We refer the reader to [16] for the theory of BMO martingales and we just recall the properties that we will use in the sequel. Let $\Phi_{t}=\int_{0}^{t} \phi_{s} d W_{s}, t \in[0, T]$ be a real square integrable martingale with respect to the Brownian filtration. Then $\Phi$ is a BMO martingale if

$$
\|\Phi\|_{B M O}=\sup _{\tau \in[0, T]} \mathbb{E}\left[\langle\Phi\rangle_{T}-\langle\Phi\rangle_{\tau} \mid \mathcal{F}_{\tau}\right]^{1 / 2}=\sup _{\tau \in[0, T]} \mathbb{E}\left[\int_{\tau}^{T} \phi_{s}^{2} d s \mid \mathcal{F}_{\tau}\right]^{1 / 2}<+\infty
$$

where the supremum is taken over all stopping times in $[0, T] ;\langle\Phi\rangle$ denotes the quadratic variation of $\Phi$. In our case, the very important feature of BMO martingales is the following lemma:

Lemma 2.1. Let $\Phi$ be a BMO martingale. Then we have:

1. The stochastic exponential

$$
\mathcal{E}(\Phi)_{t}=\mathcal{E}_{t}=\exp \left(\int_{0}^{t} \phi_{s} d W_{s}-\frac{1}{2} \int_{0}^{t}\left|\phi_{s}\right|^{2} d s\right), \quad 0 \leqslant t \leqslant T
$$

is a uniformly integrable martingale.
2. Thanks to the reverse Hölder inequality, there exists $p>1$ such that $\mathcal{E}_{T} \in L^{p}$. The maximal $p$ with this property can be expressed in terms of the BMO norm of $\Phi$.
3. $\forall n \in \mathbb{N}^{*}, \mathbb{E}\left[\left(\int_{0}^{T}\left|\phi_{s}\right|^{2} d s\right)^{n}\right] \leqslant n!\|\Phi\|_{B M O}^{2 n}$.

### 2.3 The backward-forward system

Given functions $b, \sigma, g$ and $f$, for $x \in \mathbb{R}^{d}$ we will deal with the solution $(X, Y, Z)$ to the following system of (decoupled) backward-forward stochastic differential equations: for $t \in[0, T]$,

$$
\begin{align*}
X_{t} & =x+\int_{0}^{t} b\left(s, X_{s}\right) d s+\int_{0}^{t} \sigma(s) d W_{s}  \tag{2.1}\\
Y_{t} & =g\left(X_{T}\right)+\int_{t}^{T} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s-\int_{t}^{T} Z_{s} d W_{s} \tag{2.2}
\end{align*}
$$

For the functions that appear in the above system of equations we give some general assumptions.
(HX0). $b:[0, T] \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}, \sigma:[0, T] \rightarrow \mathbb{R}^{d \times d}$ are measurable functions. There exist four positive constants $M_{b}, K_{b}, M_{\sigma}$ and $K_{\sigma}$ such that $\forall t, t^{\prime} \in[0, T], \forall x, x^{\prime} \in \mathbb{R}^{d}$,

$$
\begin{aligned}
|b(t, x)| & \leqslant M_{b}(1+|x|) \\
\left|b(t, x)-b\left(t^{\prime}, x^{\prime}\right)\right| & \leqslant K_{b}\left(\left|x-x^{\prime}\right|+\left|t-t^{\prime}\right|^{1 / 2}\right) \\
|\sigma(t)| & \leqslant M_{\sigma} \\
\left|\sigma(t)-\sigma\left(t^{\prime}\right)\right| & \leqslant K_{\sigma}\left|t-t^{\prime}\right|
\end{aligned}
$$

(HY0). $f:[0, T] \times \mathbb{R}^{d} \times \mathbb{R} \times \mathbb{R}^{1 \times d} \rightarrow \mathbb{R}, g: \mathbb{R}^{d} \rightarrow \mathbb{R}$ are measurable functions. There exist five positive constants $M_{f}, K_{f, x}, K_{f, y}, K_{f, z}$ and $M_{g}$ such that $\forall t \in[0, T], \forall x, x^{\prime} \in \mathbb{R}^{d}, \forall y, y^{\prime} \in \mathbb{R}$, $\forall z, z^{\prime} \in \mathbb{R}^{1 \times d}$,

$$
\begin{aligned}
|f(t, x, y, z)| & \leqslant M_{f}\left(1+|y|+|z|^{2}\right), \\
\left|f(t, x, y, z)-f\left(t, x^{\prime}, y^{\prime}, z^{\prime}\right)\right| & \leqslant K_{f, x}\left|x-x^{\prime}\right|+K_{f, y}\left|y-y^{\prime}\right|+\left(K_{f, z}+L_{f, z}\left(|z|+\left|z^{\prime}\right|\right)\right)\left|z-z^{\prime}\right|, \\
|g(x)| & \leqslant M_{g} .
\end{aligned}
$$

We next recall some results on BSDEs with quadratic growth. For their original version and their proof we refer to [17], [2] and [14].

Theorem 2.2. Under (HXO), (HYO), the system (2.1)-(2.2) has a unique solution $(X, Y, Z) \in \mathcal{S}^{2} \times \mathcal{S}^{\infty} \times$ $\mathcal{M}^{2}$. The martingale $Z * W$ belongs to the space of $B M O$ martingales and $\|Z * W\|_{B M O}$ only depends on $T, M_{g}$ and $M_{f}$. Moreover, there exists $r>1$ such that $\mathcal{E}(Z * W) \in L^{r}$.

## 3 Some useful estimates of $Z$

### 3.1 A first bound for $Z$

Theorem 3.1. Suppose that (HXO), (HYO) hold and that $g$ is Lipschitz with Lipschitz constant $K_{g}$. Then, there exists a version of $Z$ such that, $\forall t \in[0, T]$,

$$
\left|Z_{t}\right| \leqslant e^{\left(2 K_{b}+K_{f, y}\right) T} M_{\sigma}\left(K_{g}+T K_{f, x}\right) .
$$

Proof. Firstly, we suppose that $b, g$ and $f$ are differentiable with respect to $x, y$ and $z$. Then $(X, Y, Z)$ is differentiable with respect to $x$ and $(\nabla X, \nabla Y, \nabla Z)$ is solution of

$$
\begin{align*}
\nabla X_{t}= & I_{d}+\int_{0}^{t} \nabla b\left(s, X_{s}\right) \nabla X_{s} d s  \tag{3.1}\\
\nabla Y_{t}= & \nabla g\left(X_{T}\right) \nabla X_{T}-\int_{t}^{T} \nabla Z_{s} d W_{s}  \tag{3.2}\\
& +\int_{t}^{T} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s}+\nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla Y_{s}+\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla Z_{s} d s
\end{align*}
$$

where $\nabla X_{t}=\left(\partial X_{t}^{i} / \partial x^{j}\right)_{1 \leqslant i, j \leqslant d}, \nabla Y_{t}={ }^{t}\left(\partial Y_{t} / \partial x^{j}\right)_{1 \leqslant j \leqslant d} \in \mathbb{R}^{1 \times d}, \nabla Z_{t}=\left(\partial Z_{t}^{i} / \partial x^{j}\right)_{1 \leqslant i, j \leqslant d}$ and $\int_{t}^{T} \nabla Z_{s} d W_{s}$ means

$$
\sum_{1 \leqslant i \leqslant d} \int_{t}^{T}\left(\nabla Z_{s}\right)^{i} d W_{s}^{i}
$$

with $(\nabla Z)^{i}$ denoting the $i$-th line of the $d \times d$ matrix process $\nabla Z$. Thanks to usual transformations on the BSDE we obtain

$$
\begin{aligned}
e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla Y_{t}= & e^{\int_{0}^{T} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla g\left(X_{T}\right) \nabla X_{T}-\int_{t}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla Z_{s} d \tilde{W}_{s} \\
& +\int_{t}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s,
\end{aligned}
$$

with $d \tilde{W}_{s}=d W_{s}-\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s$. We have

$$
\begin{aligned}
\left\|\int_{0} \nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d W_{s}\right\|_{B M O}^{2} & =\sup _{\tau \in[0, T]} \mathbb{E}\left[\int_{\tau}^{T}\left|\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right)\right|^{2} d s \mid \mathcal{F}_{\tau}\right] \\
& \leqslant C\left(1+\sup _{\tau \in[0, T]} \mathbb{E}\left[\int_{\tau}^{T}\left|Z_{s}\right|^{2} d s \mid \mathcal{F}_{\tau}\right]\right) \\
& =C\left(1+\|Z * W\|_{B M O}^{2}\right) .
\end{aligned}
$$

Since $Z * W$ belongs to the space of BMO martingales, $\left\|\int_{0}^{\cdot} \nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d W_{s}\right\|_{B M O}<+\infty$. Lemma 2.1 gives us that $\mathcal{E}\left(\int_{0} \nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d W_{s}\right)_{t}$ is a uniformly integrable martingale, so we are able to apply Girsanov's theorem: there exists a probability $\mathbb{Q}$ under which $(\tilde{W})_{t \in[0, T]}$ is a Brownian motion. Then,

$$
\begin{aligned}
e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla Y_{t}= & \mathbb{E}^{\mathbb{Q}}\left[e^{\int_{0}^{T} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla g\left(X_{T}\right) \nabla X_{T}\right. \\
& \left.+\int_{t}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s \mid \mathcal{F}_{t}\right]
\end{aligned}
$$

and

$$
\begin{equation*}
\left|\nabla Y_{t}\right| \leqslant e^{\left(K_{b}+K_{f, y}\right) T}\left(K_{g}+T K_{f, x}\right), \tag{3.3}
\end{equation*}
$$

because $\left|\nabla X_{t}\right| \leqslant e^{K_{b} T}$. Moreover, thanks to the Malliavin calculus, it is classical to show that a version of $\left(Z_{t}\right)_{t \in[0, T]}$ is given by $\left(\nabla Y_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)\right)_{t \in[0, T]}$. So we obtain

$$
\left|Z_{t}\right| \leqslant e^{K_{b} T} M_{\sigma}\left|\nabla Y_{t}\right| \leqslant e^{\left(2 K_{b}+K_{f, y}\right) T} M_{\sigma}\left(K_{g}+T K_{f, x}\right), \quad \text { a.s. }
$$

because $\left|\nabla X_{t}^{-1}\right| \leqslant e^{K_{b} T}$.
When $b, g$ and $f$ are not differentiable, we can also prove the result by a standard approximation and stability results for BSDEs with linear growth.

### 3.2 A time dependent estimate of $Z$

We will introduce two alternative assumptions.
(HX1). $\quad b$ is differentiable with respect to $x$ and $\sigma$ is differentiable with respect to $t$. There exists $\lambda \in \mathbb{R}^{+}$such that $\forall \eta \in \mathbb{R}^{d}$

$$
\begin{equation*}
\left.\mid{ }^{t} \eta \sigma(s){ }^{t} \sigma(s)^{t} \nabla b(s, x)-{ }^{t} \sigma^{\prime}(s)\right]\left.\eta|\leqslant \lambda|{ }^{t} \eta \sigma(s)\right|^{2} . \tag{3.4}
\end{equation*}
$$

(HX1'). $\quad \sigma$ is invertible and $\forall t \in[0, T],\left|\sigma(t)^{-1}\right| \leqslant M_{\sigma^{-1}}$.
Example. Assumption (HX1) is verified when, $\forall s \in[0, T], \nabla b(s,$.$) commutes with \sigma(s)$ and $\exists A$ : $[0, T] \rightarrow \mathbb{R}^{d \times d}$ bounded such that $\sigma^{\prime}(t)=\sigma(t) A(t)$.

Theorem 3.2. Suppose that (HXO), (HYO) hold and that (HX1) or (HX1') holds. Moreover, suppose that $g$ is lower (or upper) semi-continuous. Then there exists a version of $Z$ and there exist two constants $C, C^{\prime} \in \mathbb{R}^{+}$that depend only in $T, M_{g}, M_{f}, K_{f, x}, K_{f, y}, K_{f, z}$ and $L_{f, z}$ such that, $\forall t \in[0, T[$,

$$
\left|Z_{t}\right| \leqslant C+C^{\prime}(T-t)^{-1 / 2}
$$

Proof. In a first time, we will suppose that (HX1) holds and that $f, g$ are differentiable with respect to $x, y$ and $z$. Then $(Y, Z)$ is differentiable with respect to $x$ and $(\nabla Y, \nabla Z)$ is the solution of the BSDE

$$
\begin{aligned}
\nabla Y_{t}= & \nabla g\left(X_{T}\right) \nabla X_{T}-\int_{t}^{T} \nabla Z_{s} d W_{s} \\
& +\int_{t}^{T} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s}+\nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla Y_{s}+\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla Z_{s} d s
\end{aligned}
$$

Thanks to usual transformations we obtain

$$
\begin{aligned}
& e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla Y_{t}+\int_{0}^{t} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s= \\
& e^{\int_{0}^{T} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla g\left(X_{T}\right) \nabla X_{T}+\int_{0}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s \\
& -\int_{t}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla Z_{s} d \tilde{W}_{s},
\end{aligned}
$$

with $d \tilde{W}_{s}=d W_{s}-\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s$. We can rewrite it as

$$
\begin{equation*}
F_{t}=F_{T}-\int_{t}^{T} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla Z_{s} d \tilde{W}_{s} \tag{3.5}
\end{equation*}
$$

with

$$
F_{t}:=e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} \nabla Y_{t}+\int_{0}^{t} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s
$$

$Z * W$ belongs to the space of BMO martingales so we are able to apply Girsanov's theorem: there exists a probability $\mathbb{Q}$ under which $(\tilde{W})_{t \in[0, T]}$ is a Brownian motion. Thanks to the Malliavin calculus, it is possible to show that $\left(\nabla Y_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)\right)_{t \in[0, T]}$ is a version of $Z$. Now we define:

$$
\begin{aligned}
\alpha_{t} & :=\int_{0}^{t} e^{\int_{0}^{s} \nabla_{y} f\left(u, X_{u}, Y_{u}, Z_{u}\right) d u} \nabla_{x} f\left(s, X_{s}, Y_{s}, Z_{s}\right) \nabla X_{s} d s\left(\nabla X_{t}\right)^{-1} \sigma(t), \\
\tilde{Z}_{t} & :=F_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)=e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} Z_{t}+\alpha_{t}, \quad \text { a.s. } \\
\tilde{F}_{t} & :=e^{\lambda t} F_{t}\left(\nabla X_{t}\right)^{-1}
\end{aligned}
$$

Since $d \nabla X_{t}=\nabla b\left(t, X_{t}\right) \nabla X_{t} d t$, then $d\left(\nabla X_{t}\right)^{-1}=-\left(\nabla X_{t}\right)^{-1} \nabla b\left(t, X_{t}\right) d t$ and thanks to Itô's formula,

$$
d \tilde{Z}_{t}=d F_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)-F_{t}\left(\nabla X_{t}\right)^{-1} \nabla b\left(t, X_{t}\right) \sigma(t) d t+F_{t}\left(\nabla X_{t}\right)^{-1} \sigma^{\prime}(t) d t
$$

and

$$
d\left(e^{\lambda t} \tilde{Z}_{t}\right)=\tilde{F}_{t}\left(\lambda I d-\nabla b\left(t, X_{t}\right)\right) \sigma(t) d t+\tilde{F}_{t} \sigma^{\prime}(t) d t+e^{\lambda t} d F_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)
$$

Finally,

$$
\left.d\left|e^{\lambda t} \tilde{Z}_{t}\right|^{2}=d\langle M\rangle_{t}+2\left[\lambda\left|\tilde{F}_{t} \sigma(t)\right|^{2}-\tilde{F}_{t} \sigma(t){ }^{t} \sigma(t)^{t} \nabla b\left(t, X_{t}\right)-{ }^{t} \sigma^{\prime}(t)\right]^{t} \tilde{F}_{t}\right] d t+d M_{t}^{*}
$$

with $M_{t}:=\int_{0}^{t} e^{\lambda s} d F_{s}\left(\nabla X_{s}\right)^{-1} \sigma(s)$ and $M_{t}^{*}$ a $\mathbb{Q}$-martingale. Thanks to the assumption (HX1) we are able to conclude that $\left|e^{\lambda t} \tilde{Z}_{t}\right|^{2}$ is a $\mathbb{Q}$-submartingale. Hence,

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}}\left[\int_{t}^{T} e^{2 \lambda s}\left|\tilde{Z}_{s}\right|^{2} d s \mid \mathcal{F}_{t}\right] & \geqslant e^{2 \lambda t}\left|\tilde{Z}_{t}\right|^{2}(T-t) \\
& \geqslant e^{2 \lambda t}\left|e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} Z_{t}+\alpha_{t}\right|^{2}(T-t) \quad \text { a.s. }
\end{aligned}
$$

which implies

$$
\begin{aligned}
\left|Z_{t}\right|^{2}(T-t) & =e^{-2 \lambda t} e^{-2 \int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s} e^{2 \lambda t} \mid e_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s \\
& \leqslant C\left(e^{2 \lambda t}\left|e^{\int_{0}^{t} \nabla_{y} f\left(s, X_{s}, Y_{s}, Z_{s}\right) d s}\right|^{2}(T-t)\right. \\
& \leqslant C\left(\left.\mathbb{E}^{2}\right|^{2}+1\right)(T-t) \\
& \left.\left.\leqslant \int_{t}^{T} e^{2 \lambda s}\left|\tilde{Z}_{s}\right|^{2} d s \mid \mathcal{F}_{t}\right]+(T-t)\right) \text { a.s., }
\end{aligned}
$$

with C a constant that only depends on $T, K_{b}, M_{\sigma}, K_{f, x}, K_{f, y}$ and $\lambda$. Moreover, we have, a.s.,

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}}\left[\int_{t}^{T} e^{2 \lambda s}\left|\tilde{Z}_{s}\right|^{2} d s \mid \mathcal{F}_{t}\right] & \leqslant C \mathbb{E}^{\mathbb{Q}}\left[\int_{t}^{T}\left|Z_{s}\right|^{2}+\left|\alpha_{s}\right|^{2} d s \mid \mathcal{F}_{t}\right] \\
& \leqslant C\left(\|Z\|_{B M O(\mathbb{Q})}^{2}+(T-t)\right) .
\end{aligned}
$$

But $\|Z\|_{B M O(\mathbb{Q})}$ does not depend on $K_{g}$ because $(Y, Z)$ is a solution of the following quadratic BSDE:

$$
\begin{equation*}
Y_{t}=g\left(X_{T}\right)+\int_{t}^{T}\left(f\left(s, X_{s}, Y_{s}, Z_{s}\right)-Z_{s} \nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right)\right) d s-\int_{t}^{T} Z_{s} d \tilde{W}_{s} \tag{3.6}
\end{equation*}
$$

Finally $\left|Z_{t}\right| \leqslant C\left(1+(T-t)^{-1 / 2}\right)$ a.s..
When $\sigma$ is invertible, the inequality (3.4) is verified with $\lambda:=M_{\sigma^{-1}}\left(M_{\sigma} K_{b}+K_{\sigma}\right)$. Since this $\lambda$ does not depend on $\nabla b$ and $\sigma^{\prime}$, we can prove the result when $b(t,$.$) and \sigma$ are not differentiable by a standard approximation and stability results for BSDEs with linear growth. So, we are allowed to replace assumption (HX1) by (HX1').

When $f$ is not differentiable and $g$ is only Lipschitz we can prove the result by a standard approximation and stability results for linear BSDEs. But we notice that our estimation on $Z$ does not depend on $K_{g}$. This allows us to weaken the hypothesis on $g$ further: when $g$ is only lower or upper semi-continuous the result stays true. The proof is the same as the proof of Proposition 4.3 in [ [8].
Remark 3.3. The previous proof gives us a more precise estimation for a version of $Z$ when $f$ is differentiable with respect to $z: \forall t \in[0, T]$,

$$
\left|Z_{t}\right| \leqslant C+C^{\prime} \mathbb{E}^{\mathbb{Q}}\left[\int_{t}^{T}\left|Z_{s}\right|^{2} d s \mid \mathcal{F}_{t}\right]^{1 / 2}(T-t)^{-1 / 2} .
$$

Remark 3.4. When assumptions (HXI) or (HXI') are not verified, the process $Z$ may blow up before $T$. Zhang gives an example of such a phenomenon in dimension 1: we refer the reader to example 1 in [27].

### 3.3 Zhang's path regularity Theorem

Let $0=t_{0}<t_{1}<\ldots<t_{n}=T$ be any given partition of $[0, T]$, and denote $\delta_{n}$ the mesh size of this partition. We define a set of random variables

$$
\bar{Z}_{t_{i}}=\frac{1}{t_{i+1}-t_{i}} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}} Z_{s} d s \mid \mathcal{F}_{t_{i}}\right], \quad \forall i \in\{0, \ldots, n-1\} .
$$

Then we are able to precise Theorem 3.4.3 in [2]:
Theorem 3.5. Suppose that (HXO), (HYO) hold and g is a Lipschitz function, with Lipschitz constant $K_{g}$. Then we have

$$
\sum_{i=0}^{n-1} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-\bar{Z}_{t_{i}}\right|^{2} d t\right] \leqslant C\left(1+K_{g}^{2}\right) \delta_{n},
$$

where $C$ is a positive constant independent of $\delta_{n}$ and $K_{g}$.

Proof. We will follow the proof of Theorem 5.6., in [14]: we just need to specify how the estimate depends on $K_{g}$. Firstly, it is not difficult to show that $\bar{Z}_{t_{i}}$ is the best $\mathcal{F}_{t_{i}}$-measurable approximation of $Z$ in $\mathcal{M}^{2}\left(\left[t_{i}, t_{i+1}\right]\right)$, i.e.

$$
\mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-\bar{Z}_{t_{i}}\right|^{2} d t\right]=\inf _{Z_{i} \in L^{2}\left(\Omega, \mathcal{F}_{t_{i}}\right)} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-Z_{i}\right|^{2} d t\right]
$$

In particular,

$$
\mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-\bar{Z}_{t_{i}}\right|^{2} d t\right] \leqslant \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-Z_{t_{i}}\right|^{2} d t\right]
$$

In the same spirit as previous proofs, we suppose in a first time that $b, g$ and $f$ are differentiable with respect to $x, y$ and $z$. So,

$$
Z_{t}-Z_{t_{i}}=\nabla Y_{t}\left(\nabla X_{t}\right)^{-1} \sigma(t)-\nabla Y_{t_{i}}\left(\nabla X_{t_{i}}\right)^{-1} \sigma\left(t_{i}\right)=I_{1}+I_{2}+I_{3}, \quad \text { a.s. }
$$

with $I_{1}=\nabla Y_{t}\left(\nabla X_{t}\right)^{-1}\left(\sigma(t)-\sigma\left(t_{i}\right)\right), I_{2}=\nabla Y_{t}\left(\left(\nabla X_{t}\right)^{-1}-\left(\nabla X_{t_{i}}\right)^{-1}\right) \sigma\left(t_{i}\right)$ and $I_{3}=\nabla\left(Y_{t}-\right.$ $\left.Y_{t_{i}}\right)\left(\nabla X_{t_{i}}\right)^{-1} \sigma\left(t_{i}\right)$. Firstly, thanks to the estimation (3.3) we have

$$
\left|I_{1}\right|^{2} \leqslant\left|\nabla Y_{t}\right|^{2} e^{2 K_{b} T} K_{\sigma}^{2}\left|t_{i+1}-t_{i}\right|^{2} \leqslant C\left(1+K_{g}^{2}\right) \delta_{n}^{2}
$$

We obtain the same estimation for $\left|I_{2}\right|$ because

$$
\left|\left(\nabla X_{t}\right)^{-1}-\left(\nabla X_{t_{i}}\right)^{-1}\right| \leqslant\left|\int_{t_{i}}^{t}\left(\nabla X_{s}\right)^{-1} \nabla b\left(s, X_{s}\right) d s\right| \leqslant K_{b} e^{K_{b} T}\left|t-t_{i}\right|
$$

Lastly, $\left|I_{3}\right| \leqslant M_{\sigma} e^{K_{b} T}\left|\nabla Y_{t}-\nabla Y_{t_{i}}\right|$. So,

$$
\sum_{i=0}^{n-1} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|I_{3}\right|^{2} d t\right] \leqslant C \delta_{n} \sum_{i=0}^{n-1} \mathbb{E}\left[\underset{t \in\left[t_{i}, t_{i+1}\right]}{\operatorname{ess} \sup }\left|\nabla Y_{t}-\nabla Y_{t_{i}}\right|^{2}\right]
$$

By using the BSDE (3.2), (HY0), the estimate on $\nabla X_{s}$ and the estimate (3.3), we have

$$
\begin{aligned}
& \left|\nabla Y_{t}-\nabla Y_{t_{i}}\right|^{2} \\
& \leqslant C\left(\int_{t_{i}}^{t}\left(C\left(1+K_{g}\right)+\left|\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right)\right|\left|\nabla Z_{s}\right|\right) d s\right)^{2}+C\left(\int_{t_{i}}^{t} \nabla Z_{s} d W_{s}\right)^{2}
\end{aligned}
$$

The inequalities of Hölder and Burkholder-Davis-Gundy give us

$$
\begin{aligned}
& \sum_{i=0}^{n-1} \mathbb{E}\left[\underset{t \in\left[t_{i}, t_{i+1}\right]}{\operatorname{ess} \sup }\left|\nabla Y_{t}-\nabla Y_{t_{i}}\right|^{2}\right] \\
& \leqslant C\left(1+K_{g}^{2}\right)+C \sum_{i=0}^{n-1} \mathbb{E}\left(\int_{t_{i}}^{t_{i+1}}\left|\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right)\right|\left|\nabla Z_{s}\right| d s\right)^{2}+C \mathbb{E}\left(\int_{t_{i}}^{t_{i+1}}\left|\nabla Z_{s}\right|^{2} d s\right) \\
& \leqslant C\left(1+K_{g}^{2}\right)+C \mathbb{E}\left[\left(\int_{0}^{T}\left|\nabla_{z} f\left(s, X_{s}, Y_{s}, Z_{s}\right)\right|\left|\nabla Z_{s}\right| d s\right)^{2}+\int_{0}^{T}\left|\nabla Z_{s}\right|^{2} d s\right] \\
& \leqslant C\left(1+K_{g}^{2}\right)+C \mathbb{E}\left[\left(\int_{0}^{T}\left(1+\left|Z_{s}\right|^{2}\right) d s\right)\left(\int_{0}^{T}\left|\nabla Z_{s}\right|^{2} d s\right)+\int_{0}^{T}\left|\nabla Z_{s}\right|^{2} d s\right] \\
& \leqslant C\left(1+K_{g}^{2}\right)+C\left(1+\mathbb{E}\left[\left(\int_{0}^{T}\left|Z_{s}\right|^{2} d s\right)^{1 / p}\right) \mathbb{E}\left[\left(\int_{0}^{T}\left|\nabla Z_{s}\right|^{2} d s\right)^{q}\right]^{1 / q},\right.
\end{aligned}
$$

for all $p>1$ and $q>1$ such that $1 / p+1 / q=1$. But, $(\nabla Y, \nabla Z)$ is solution of BSDE (3.2), so, from Corollary 9 in [2], there exists $q$ that only depends on $\|Z * W\|_{B M O}$ such that

$$
\mathbb{E}\left[\left(\int_{0}^{T}\left|\nabla Z_{s}\right|^{2} d s\right)^{q}\right]^{1 / q} \leqslant C\left(1+K_{g}^{2}\right)
$$

Moreover, we can apply Lemma 2.1 to obtain the estimate

$$
\mathbb{E}\left[\left(\int_{0}^{T}\left|Z_{s}\right|^{2} d s\right)^{p}\right]^{1 / p} \leqslant C\|Z\|_{B M O}^{2} \leqslant C
$$

Finally,

$$
\sum_{i=0}^{n-1} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|I_{3}\right|^{2} d t\right] \leqslant C\left(1+K_{g}^{2}\right) \delta_{n}
$$

and

$$
\begin{aligned}
\sum_{i=0}^{n-1} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left|Z_{t}-\bar{Z}_{t_{i}}\right|^{2} d t\right] & \leqslant \sum_{i=0}^{n-1} \mathbb{E}\left[\int_{t_{i}}^{t_{i+1}}\left(\left|I_{1}\right|^{2}+\left|I_{2}\right|^{2}+\left|I_{3}\right|^{2}\right) d t\right] \\
& \leqslant C\left(1+K_{g}^{2}\right) \delta_{n}
\end{aligned}
$$

## 4 Convergence of a modified time discretization scheme for the BSDE

### 4.1 An approximation of the quadratic BSDE

In a first time we will approximate our quadratic $\operatorname{BSDE}(2.2)$ by another one. We set $\varepsilon \in] 0, T[$ and $N \in \mathbb{N}$. Let $\left(Y_{t}^{N, \varepsilon}, Z_{t}^{N, \varepsilon}\right)$ the solution of the BSDE

$$
\begin{equation*}
Y_{t}^{N, \varepsilon}=g_{N}\left(X_{T}\right)+\int_{t}^{T} f^{\varepsilon}\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right) d s-\int_{t}^{T} Z_{s}^{N, \varepsilon} d W_{s} \tag{4.1}
\end{equation*}
$$

with

$$
f^{\varepsilon}(s, x, y, z):=\mathbb{1}_{s \leqslant T-\varepsilon} f(s, x, y, z)+\mathbb{1}_{s>T-\varepsilon} f(s, x, y, 0)
$$

and $g_{N}$ a Lipschitz approximation of $g$ with Lipschitz constant $N . f^{\varepsilon}$ verifies assumption (HY0) with the same constants as $f$. Since $g_{N}$ is a Lipschitz function, $Z^{N, \varepsilon}$ has a bounded version and the BSDE (4.1) is a BSDE with a linear growth. Moreover, we can apply Theorem 3.2 to obtain:

Proposition 4.1. Let us assume that (HXO), (HYO) and (HX1) or (HX1') hold. There exists a version of $Z^{N, \varepsilon}$ and there exist three constants $M_{z, 1}, M_{z, 2}, M_{z, 3} \in \mathbb{R}^{+}$that do not depend on $N$ and $\varepsilon$ such that, $\forall s \in[0, T]$,

$$
\left|Z_{s}^{N, \varepsilon}\right| \leqslant\left(M_{z, 1}+\frac{M_{z, 2}}{(T-s)^{1 / 2}}\right) \wedge\left(M_{z, 3}(N+1)\right)
$$

Thanks to BMO tools we have a stability result for quadratic BSDEs (see [2] and [14]):

Proposition 4.2. Let us assume that (HXO) and (HYO) hold. There exists a constant $C$ that does not depend on $N$ and $\varepsilon$ such that

$$
\mathbb{E}\left[\sup _{t \in[0, T]}\left|Y_{t}^{N, \varepsilon}-Y_{t}\right|^{2}\right]+\mathbb{E}\left[\int_{0}^{T}\left|Z_{t}^{N, \varepsilon}-Z_{t}\right|^{2} d t\right] \leqslant C\left(e_{1}(N)+e_{2}(N, \varepsilon)\right)
$$

with

$$
\begin{gathered}
e_{1}(N):=\mathbb{E}\left[\left|g_{N}\left(X_{T}\right)-g\left(X_{T}\right)\right|^{2 q}\right]^{1 / q}, 乙 \\
e_{2}(N, \varepsilon):=\mathbb{E}\left[\left(\int_{T-\varepsilon}^{T}\left|f\left(t, X_{t}, Y_{t}^{N, \varepsilon}, Z_{t}^{N, \varepsilon}\right)-f\left(t, X_{t}, Y_{t}^{N, \varepsilon}, 0\right)\right| d t\right)^{2 q}\right]^{1 / q}
\end{gathered}
$$

and $q$ defined in Theorem 2.2.
Then, in a second time, we will approximate our modified backward-forward system by a discretetime one. We will slightly modify the classical discretization by using a non equidistant net with $2 n+1$ discretization times. We define the $n+1$ first discretization times on $[0, T-\varepsilon]$ by

$$
t_{k}=T\left(1-\left(\frac{\varepsilon}{T}\right)^{k / n}\right)
$$

and we use an equidistant net on $[T-\varepsilon, T]$ for the last $n$ discretization times:

$$
t_{k}=T-\left(\frac{2 n-k}{n}\right) \varepsilon, \quad n \leqslant k \leqslant 2 n
$$

We denote the time step by $\left(h_{k}:=t_{k+1}-t_{k}\right)_{0 \leqslant k \leqslant 2 n-1}$. We consider $\left(X_{t_{k}}^{n}\right)_{0 \leqslant k \leqslant 2 n}$ the classical Euler scheme for $X$ given by

$$
\begin{align*}
X_{0}^{n} & =x \\
X_{t_{k+1}}^{n} & =X_{t_{k}}^{n}+h_{k} b\left(t_{k}, X_{t_{k}}^{n}\right)+\sigma\left(t_{k}\right)\left(W_{t_{k+1}}-W_{t_{k}}\right), \quad 0 \leqslant k \leqslant 2 n-1 \tag{4.2}
\end{align*}
$$

We denote $\rho_{s}: \mathbb{R}^{1 \times d} \rightarrow \mathbb{R}^{1 \times d}$ the projection on the ball

$$
B\left(0, M_{z, 1}+\frac{M_{z, 2}}{(T-s)^{1 / 2}}\right)
$$

with $M_{z, 1}$ and $M_{z, 2}$ given by Proposition 4.1. Finally we denote ( $Y^{N, \varepsilon, n}, Z^{N, \varepsilon, n}$ ) our time approximation of $\left(Y^{N, \varepsilon}, Z^{N, \varepsilon}\right)$. This couple is obtained by a slight modification of the classical dynamic programming equation:

$$
\begin{align*}
Y_{t_{2 n}}^{N, \varepsilon, n} & =g_{N}\left(X_{t_{2 n}}^{n}\right) \\
Z_{t_{k}}^{N, \varepsilon, n} & =\rho_{t_{k+1}}\left(\frac{1}{h_{k}} \mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon, n}\left(W_{t_{k+1}}-W_{t_{k}}\right)\right]\right), \quad 0 \leqslant k \leqslant 2 n-1  \tag{4.3}\\
Y_{t_{k}}^{N, \varepsilon, n} & =\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon, n}\right]+h_{k} \mathbb{E}_{t_{k}}\left[f^{\varepsilon}\left(t_{k}, X_{t_{k}}^{n}, Y_{t_{k+1}}^{N, \varepsilon, n}, Z_{t_{k}}^{N, \varepsilon, n}\right)\right], \quad 0 \leqslant k \leqslant 2 n-1, \tag{4.4}
\end{align*}
$$

[^1]where $\mathbb{E}_{t_{k}}$ stands for the conditional expectation given $\mathcal{F}_{t_{k}}$. Let us notice that the classical dynamic programming equation do not use a projection in (4.3): it is the only difference with our time approximation, see e.g. [11] for the classical case. This projection comes directly from the estimate of $Z$ in Proposition 4.1. The aim of our work is to study the error of discretization
$$
e(N, \varepsilon, n):=\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}\right|^{2}\right]+\sum_{k=0}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}\right|^{2} d t\right]
$$

It is easy to see that

$$
e(N, \varepsilon, n) \leqslant C\left(e_{1}(N)+e_{2}(N, \varepsilon)+e_{3}(N, \varepsilon, n)\right)
$$

with $e_{1}(N)$ and $e_{2}(N, \varepsilon)$ defined in Proposition 4.2, and

$$
e_{3}(N, \varepsilon, n):=\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=0}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right]
$$

### 4.2 Study of the time approximation error $e_{3}(N, \varepsilon, n)$

We need an extra assumption.
(HY1). There exists a positive constant $K_{f, t}$ such that $\forall t, t^{\prime} \in[0, T], \forall x \in \mathbb{R}^{d}, \forall y \in \mathbb{R}, \forall z \in \mathbb{R}^{1 \times d}$,

$$
\left|f(t, x, y, z)-f\left(t^{\prime}, x, y, z\right)\right| \leqslant K_{f, t}\left|t-t^{\prime}\right|^{1 / 2}
$$

Moreover, we set $\varepsilon=T n^{-a}$ and $N=n^{b}$, with $a, b \in \mathbb{R}^{+, *}$ two parameters. Before giving our error estimates, we recall two technical lemmas that we will prove in the appendix.

Lemma 4.3. For all constant $M>0$ there exists a constant $C$ that depends only on $T, M$ and $a$, such that

$$
\prod_{i=0}^{2 n-1}\left(1+M h_{i}\right) \leqslant C, \quad \forall n \in \mathbb{N}^{*}
$$

Lemma 4.4. For all constants $M_{1}>0$ and $M_{2}>0$ there exists a constant $C$ that depends only on $T$, $M_{1}, M_{2}$ and $a$, such that

$$
\prod_{i=0}^{n-1}\left(1+M_{1} h_{i}+M_{2} \frac{h_{i}}{T-t_{i+1}}\right) \leqslant C n^{a M_{2}}
$$

Firstly, we give a convergence result for the Euler scheme.
Proposition 4.5. Assume (HXO) holds. Then there exists a constant $C$ that does not depend on $n$, such that

$$
\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|X_{t_{k}}-X_{t_{k}}^{n}\right|^{2}\right] \leqslant C \frac{\ln n}{n}
$$

Proof. We just have to copy the classical proof to obtain, thanks to Lemma 4.3,

$$
\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|X_{t_{k}}-X_{t_{k}}^{n}\right|^{2}\right] \leqslant C \sup _{0 \leqslant i \leqslant 2 n-1} h_{i}=C h_{0}
$$

But

$$
h_{0}=T\left(1-n^{-a / n}\right) \leqslant C \frac{\ln n}{n},
$$

because $\left(1-n^{-a / n}\right) \sim a T \frac{\ln n}{n}$ when $n \rightarrow+\infty$, so the proof is ended.
Now, let us treat the BSDE approximation. In a first time we will study the time approximation error on $[T-\varepsilon, T]$.

Proposition 4.6. Assume that (HXO), (HYO) and (HY1) hold. Then there exists a constant $C$ that does not depend on $n$ and such that

$$
\sup _{n \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=n}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant \frac{C \ln n}{n^{1-2 b}} .
$$

Proof. The BSDE (4.1) has a linear growth with respect to $z$ on $[T-\varepsilon, T]$ so we are allowed to apply classical results which give us that

$$
\begin{aligned}
\sup _{n \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=n}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] & \leqslant C\left(\mathbb{E}\left[\left|g_{N}\left(X_{T}\right)-g_{N}\left(X_{T}^{n}\right)\right|^{2}\right]+\frac{\varepsilon}{n}\right) \\
& \leqslant C\left(\frac{\ln n}{n^{1-2 b}}+\frac{\varepsilon}{n}\right)
\end{aligned}
$$

by using the fact that $g_{N}$ is $N$-Lipschitz and by applying Proposition 4.5.

## Remark 4.7.

- When $a \geqslant 1-2 b$, then $\varepsilon=T n^{-a}=o\left(n^{2 b-1} \ln n\right)$. So we do not need to have a discretization grid on $[T-\varepsilon, T]: n+2$ points of discretization are sufficient on $[0, T]$.
- When $a<1-2 b$, then is is possible to take only $\left\lceil n^{c}\right\rceil$ discretization points on $[T-\varepsilon, T]$ with $a+c=1-2 b$. In this case the error bound becomes

$$
\sup _{n \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=n}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant C\left(\frac{\ln n}{n^{1-2 b}}+\frac{1}{n^{a+c}}\right),
$$

and the Proposition 4.6 stay true.
Now, let us see what happens on $[0, T-\varepsilon]$.
Theorem 4.8. Assume that (HXO), (HYO), (HY1) and (HX1) or (HX1') hold. Then for all $\eta>0$, there exists a constant $C$ that does not depend on $N, \varepsilon$ and $n$, such that

$$
\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=0}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant \frac{C}{n^{1-2 b-K a}},
$$

with $K=4(1+\eta) L_{f, z}^{2} M_{z, 2}^{2}$.

Proof. Firstly, we will study the error on $Y$. From (4.1) and (4.4) we get
$Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}=\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right]+\mathbb{E}_{t_{k}} \int_{t_{k}}^{t_{k+1}}\left(f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)-f\left(t_{k}, X_{t_{k}}^{n}, Y_{t_{k+1}}^{N, \varepsilon, n}, Z_{t_{k}}^{N, \varepsilon, n}\right)\right) d s$.
We introduce a parameter $\gamma_{k}>0$ that will be chosen later. Thanks to Proposition 4.1 and assumption (HY0), $f$ is Lipschitz on $\left[t_{k}, t_{k+1}\right]$ with a Lipschitz constant $K_{k}:=K^{1}+\frac{K^{2}}{\left(T-t_{k+1}\right)^{1 / 2}}$ where $K^{2}=$ $2 L_{f, z} M_{z, 2}$. A combination of Young's inequality $(a+b)^{2} \leqslant\left(1+\gamma_{k} h_{k}\right) a^{2}+\left(1+\frac{1}{\gamma_{k} h_{k}}\right) b^{2}$ and properties of $f$ gives

$$
\begin{align*}
& \mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \\
\leqslant & \left(1+\gamma_{k} h_{k}\right) \mathbb{E}\left|\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right]\right|^{2}+(1+\eta)^{1 / 3} K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-Z_{t_{k}}^{N, \varepsilon, n}\right|^{2} d s \\
& +C\left(h_{k}+\frac{1}{\gamma_{k}}\right)\left(h_{k}^{2}+\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|X_{s}-X_{t_{k}}^{n}\right|^{2} d s+\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2} d s\right) . \tag{4.5}
\end{align*}
$$

We define

$$
\tilde{Z}_{t_{k}}^{N, \varepsilon, n}:=\frac{1}{h_{k}} \mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon, n}\left(W_{t_{k+1}}-W_{t_{k}}\right)\right]
$$

So, $Z_{t_{k}}^{N, \varepsilon, n}=\rho_{t_{k+1}}\left(\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right)$. Moreover, Proposition 4.1 implies that $Z_{s}^{N, \varepsilon}=\rho_{t_{k+1}}\left(Z_{s}^{N, \varepsilon}\right)$, and, since $\rho_{t_{k+1}}$ is 1-Lipschitz, we have

$$
\begin{equation*}
\left|Z_{s}^{N, \varepsilon}-Z_{t_{k}}^{N, \varepsilon, n}\right|^{2}=\left|\rho_{t_{k+1}}\left(Z_{s}^{N, \varepsilon}\right)-\rho_{t_{k+1}}\left(\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right)\right|^{2} \leqslant\left|Z_{s}^{N, \varepsilon}-\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right|^{2} \tag{4.6}
\end{equation*}
$$

As in Theorem 3.5, we define $\bar{Z}_{t_{k}}^{N, \varepsilon}$ by

$$
h_{k} \bar{Z}_{t_{k}}^{N, \varepsilon}:=\mathbb{E}_{t_{k}} \int_{t_{k}}^{t_{k+1}} Z_{s}^{N, \varepsilon} d s=\mathbb{E}_{t_{k}}\left(\left(Y_{t_{k+1}}^{N, \varepsilon}+\int_{t_{k}}^{t_{k+1}} f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right) d s\right)^{t}\left(W_{t_{k+1}}-W_{t_{k}}\right)\right)
$$

Clearly,

$$
\begin{equation*}
\mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right|^{2} d s=\mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{k}}^{N, \varepsilon}\right|^{2} d s+h_{k} \mathbb{E}\left|\bar{Z}_{t_{k}}^{N, \varepsilon}-\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right|^{2} \tag{4.7}
\end{equation*}
$$

The Cauchy-Schwartz inequality yields

$$
\left|\mathbb{E}_{t_{k}}\left(\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)^{t}\left(W_{t_{k+1}}-W_{t_{k}}\right)\right)\right|^{2} \leqslant h_{k}\left\{\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right\}
$$

and consequently

$$
\begin{align*}
h_{k} \mathbb{E}\left|\bar{Z}_{t_{k}}^{N, \varepsilon}-\tilde{Z}_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant & (1+\eta)^{1 / 3} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C h_{k} \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s \tag{4.8}
\end{align*}
$$

Plugging (4.7) and (4.8) into (4.5), we get:

$$
\begin{aligned}
\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant & \left(1+\gamma_{k} h_{k}\right) \mathbb{E}\left|\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right]\right|^{2} \\
& +(1+\eta) K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{k}}^{N, \varepsilon}\right|^{2} d s \\
& +C\left(h_{k}+\frac{1}{\gamma_{k}}\right)\left(h_{k}^{2}+\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|X_{s}-X_{t_{k}}^{n}\right|^{2} d s+\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2} d s\right) \\
& +(1+\eta)^{2 / 3} K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) h_{k} \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s .
\end{aligned}
$$

Now write

$$
\begin{gather*}
\mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2} \leqslant 2 \mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon}\right|^{2}+2 \mathbb{E}\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}  \tag{4.9}\\
\mathbb{E}\left|X_{s}-X_{t_{k}}^{n}\right|^{2} \leqslant 2 \mathbb{E}\left|X_{s}-X_{t_{k}}\right|^{2}+2 \mathbb{E}\left|X_{t_{k}}-X_{t_{k}}^{n}\right|^{2} \tag{4.10}
\end{gather*}
$$

we obtain

$$
\begin{aligned}
\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant & \left(1+\gamma_{k} h_{k}\right) \mathbb{E}\left|\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right]\right|^{2} \\
& +(1+\eta) K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{k}}^{N, \varepsilon}\right|^{2} d s \\
& +C\left(h_{k}+\frac{1}{\gamma_{k}}\right)\left(h_{k}^{2}+\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|X_{s}-X_{t_{k}}\right|^{2} d s+h_{k} \mathbb{E}\left|X_{t_{k}}-X_{t_{k}}^{n}\right|^{2}\right) \\
& +C\left(h_{k}+\frac{1}{\gamma_{k}}\right)\left(\int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon}\right|^{2} d s+h_{k} \mathbb{E}\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right) \\
& +(1+\eta)^{2 / 3} K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) h_{k} \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s
\end{aligned}
$$

Taking $\gamma_{k}=(1+\eta)^{2 / 3} K_{k}^{2}$ : for $h_{k}$ small enough, it gives
$\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant\left(1+C h_{k}+(1+\eta)^{2 / 3} K_{k}^{2} h_{k}\right) \mathbb{E}\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}+C h_{k}^{2}+C h_{k} \max _{0 \leqslant k \leqslant n} \mathbb{E}\left|X_{t_{k}}-X_{t_{k}}^{n}\right|^{2}$

$$
+C \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{k}}^{N, \varepsilon}\right|^{2} d s+C \int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|X_{s}-X_{t_{k}}\right|^{2} d s
$$

$$
+C \int_{t_{k}}^{t_{k+1}} \mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon}\right|^{2} d s+C h_{k} \mathbb{E} \int_{t_{k}}^{t_{k+1}} f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)^{2} d s
$$

because $K_{k}^{2} h_{k} \leqslant C\left(h_{0}+h_{k}\left(T-t_{k+1}\right)^{-1}\right) \leqslant C \frac{\ln n}{n}$. The Gronwall's lemma gives us

$$
\begin{aligned}
\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant & C \sum_{j=0}^{n-1}\left[\prod_{i=0}^{j-1}\left(1+C h_{i}+(1+\eta)^{2 / 3} K_{i}^{2} h_{i}\right)\right]\left[h_{j}^{2}+h_{j} \max _{0 \leqslant l \leqslant n} \mathbb{E}\left|X_{t_{l}}-X_{t_{l}}^{n}\right|^{2}\right. \\
& +\mathbb{E} \int_{t_{j}}^{t_{j+1}}\left(\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{j}}^{N, \varepsilon}\right|^{2}+\left|X_{s}-X_{t_{j}}\right|^{2}+\left|Y_{s}^{N, \varepsilon}-Y_{t_{j+1}}^{N, \varepsilon}\right|^{2}\right) d s \\
& \left.+h_{j} \mathbb{E} \int_{t_{j}}^{t_{j+1}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s\right] \\
& +\left[\prod_{i=0}^{n-1}\left(1+C h_{i}+(1+\eta)^{2 / 3} K_{i}^{2} h_{i}\right)\right] \mathbb{E}\left|Y_{t_{n}}^{N, \varepsilon}-Y_{t_{n}}^{N, \varepsilon, n}\right|^{2}
\end{aligned}
$$

Then, we apply Lemma 4.4:

$$
\begin{aligned}
\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant & C n^{(1+\eta)\left(K^{2}\right)^{2} a}\left[h_{0}+\max _{0 \leqslant l \leqslant n} \mathbb{E}\left|X_{t_{l}}-X_{t_{l}}^{n}\right|^{2}\right. \\
& +\sum_{j=0}^{n} \mathbb{E}\left(\int_{t_{j}}^{t_{j+1}}\left|Z_{s}^{N, \varepsilon}-\bar{Z}_{t_{j}}^{N, \varepsilon}\right|^{2}+\left|X_{s}-X_{t_{j}}\right|^{2}+\left|Y_{s}^{N, \varepsilon}-Y_{t_{j+1}}^{N, \varepsilon}\right|^{2} d s\right) \\
& \left.+h_{0} \mathbb{E} \int_{0}^{t_{n}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s+\mathbb{E}\left|Y_{t_{n}}^{N, \varepsilon}-Y_{t_{n}}^{N, \varepsilon, n}\right|^{2}\right]
\end{aligned}
$$

A classical estimation gives us $\mathbb{E}\left[\left|X_{s}-X_{t_{j}}\right|^{2}\right] \leqslant\left|s-t_{j}\right|$. Moreover, since $Z^{N, \varepsilon}$ is bounded,

$$
\begin{aligned}
\mathbb{E} \int_{0}^{t_{n}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s & \leqslant C T\left(1+\left|Y^{N, \varepsilon}\right|_{\infty}\right)+C \mathbb{E}\left[\int_{0}^{t_{n}}\left|Z_{s}^{N, \varepsilon}\right|^{4} d s\right] \\
& \leqslant C T\left(1+\left|Y^{N, \varepsilon}\right|_{\infty}\right)+C n^{2 b} \mathbb{E}\left[\int_{0}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s\right]
\end{aligned}
$$

But we have an a priori estimate for $\mathbb{E}\left[\int_{0}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s\right]$ that does not depend on $N$ and $\varepsilon$. So

$$
\begin{equation*}
\mathbb{E} \int_{0}^{t_{n}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s \leqslant C n^{2 b} \tag{4.11}
\end{equation*}
$$

With the same type of argument we also have

$$
\begin{equation*}
\mathbb{E}\left|Y_{s}^{N, \varepsilon}-Y_{t_{j+1}}^{N, \varepsilon}\right|^{2} \leqslant C h_{j} n^{2 b} \tag{4.12}
\end{equation*}
$$

If we add Zhang's path regularity theorem 3.5, Proposition 4.5 and Proposition 4.6, we finally obtain

$$
\begin{equation*}
\mathbb{E}\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2} \leqslant C n^{(1+\eta)\left(K^{2}\right)^{2} a} \frac{n^{2 b} \ln n}{n}=C \frac{\ln n}{n^{1-2 b-(1+\eta)\left(K^{2}\right)^{2} a}} \tag{4.13}
\end{equation*}
$$

Now, let us deal with the error on $Z$. First of all, (4.6) gives us

$$
\sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant \sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|\tilde{Z}_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right]
$$

For $0 \leqslant k \leqslant n-1$, we can use (4.7) and (4.8) to obtain

$$
\begin{aligned}
\mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|\tilde{Z}_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant & \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|\bar{Z}_{t_{k}}^{N, \varepsilon}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \\
& +(1+\eta)^{2 / 3} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C h_{k} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s\right]
\end{aligned}
$$

Inequality (4.11) and estimates for $Z$ give us

$$
\begin{align*}
& \sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \\
\leqslant & \sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|\bar{Z}_{t_{k}}^{N, \varepsilon}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right]  \tag{4.14}\\
& +(1+\eta)^{2 / 3} \sum_{k=0}^{n-1} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C h_{0} \mathbb{E}\left[\int_{0}^{T}\left|f\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right)\right|^{2} d s\right] \\
\leqslant & \sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|\bar{Z}_{t_{k}}^{N, \varepsilon}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \\
& +(1+\eta)^{2 / 3} \sum_{k=0}^{n-1} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
& +C \mathbb{E}\left[\left|Y_{t_{n}}^{N, \varepsilon}-Y_{t_{n}}^{N, \varepsilon, n}\right|^{2}\right]+C h_{0} n^{2 b}, \tag{4.15}
\end{align*}
$$

with an index change in the penultimate line. Then, by using (4.5) we get

$$
\begin{align*}
& (1+\eta)^{2 / 3} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
\leqslant & C \gamma_{k} h_{k} \mathbb{E}\left|\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right]\right|^{2}+(1+\eta) K_{k}^{2}\left(h_{k}+\frac{1}{\gamma_{k}}\right) \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-Z_{t_{k}}^{N, \varepsilon, n}\right|^{2} d s \\
& +C\left(h_{k}+\frac{1}{\gamma_{k}}\right) h_{k}\left(h_{k}+\sup _{s \in\left[t_{k}, t_{k+1}\right]} \mathbb{E}\left[\left|X_{s}-X_{t_{k}}^{n}\right|^{2}+\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right]\right) . \tag{4.16}
\end{align*}
$$

Thanks to (4.9), (4.10), (4.12) and a classical estimation on $\mathbb{E}\left[\left|X_{s}-X_{t_{k}}\right|^{2}\right]$ we have

$$
\sup _{s \in\left[t_{k}, t_{k+1}\right]} \mathbb{E}\left[\left|X_{s}-X_{t_{k}}^{n}\right|^{2}+\left|Y_{s}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right] \leqslant C\left(h_{k} n^{2 b}+\mathbb{E}\left[\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right]\right)
$$

Let us set $\gamma_{k}=3(1+\eta) K_{k}^{2}$. We recall that $h_{k} K_{k}^{2} \leqslant \frac{C \ln n}{n} \rightarrow 0$ when $n \rightarrow 0$. So, for $n$ big enough, (4.16) becomes

$$
\begin{aligned}
& (1+\eta)^{2 / 3} \mathbb{E}\left[\mathbb{E}_{t_{k}}\left(\left|Y_{t_{k}}^{N, \varepsilon}-Y_{t_{k}}^{N, \varepsilon, n}\right|^{2}\right)-\left|\mathbb{E}_{t_{k}}\left(Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right)\right|^{2}\right] \\
\leqslant & \frac{C \ln n}{n} \mathbb{E}\left[\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right]+\frac{1}{2} \mathbb{E} \int_{t_{k}}^{t_{k+1}}\left|Z_{s}^{N, \varepsilon}-Z_{t_{k}}^{N, \varepsilon, n}\right|^{2} d s \\
& +C h_{0} h_{k} n^{2 b} .
\end{aligned}
$$

If we inject this last estimate in 4.15) and we use Theorem 3.5, we obtain

$$
\frac{1}{2} \sum_{k=0}^{n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant C h_{0} n^{2 b}+C \ln n \sup _{0 \leqslant k \leqslant n-1} \mathbb{E}\left[\left|Y_{t_{k+1}}^{N, \varepsilon}-Y_{t_{k+1}}^{N, \varepsilon, n}\right|^{2}\right]
$$

By using (4.13) and Proposition 4.6, we finally have

$$
\sup _{0 \leqslant k \leqslant 2 n} \mathbb{E}\left[\left|Y_{t_{k}}^{N, \varepsilon, n}-Y_{t_{k}}^{N, \varepsilon}\right|^{2}\right]+\sum_{k=0}^{2 n-1} \mathbb{E}\left[\int_{t_{k}}^{t_{k+1}}\left|Z_{t_{k}}^{N, \varepsilon, n}-Z_{t}^{N, \varepsilon}\right|^{2} d t\right] \leqslant C \frac{(\ln n)^{2}}{n^{1-2 b-K a}}
$$

with $K=4(1+\eta) L_{f, z}^{2} M_{z, 2}^{2}$. Since this estimate is true for every $\eta>0$, we have proved the result.

### 4.3 Study of the global error $e(N, \varepsilon, n)$

Let us study errors $e_{1}(N)$ and $e_{2}(N, \varepsilon)$.
Proposition 4.9. Let us assume that (HXO) and (HYO) hold. There exists a constant $C>0$ such that

$$
e_{2}(N, \varepsilon) \leqslant \frac{C}{n^{2 a-4 b}}
$$

Proof. We just have to notice that $\left|f\left(t, X_{t}, Y_{t}^{N, \varepsilon}, Z_{t}^{N, \varepsilon}\right)-f\left(t, X_{t}, Y_{t}^{N, \varepsilon}, 0\right)\right| \leqslant C\left|Z_{t}^{N, \varepsilon}\right|^{2}$ and $\left|Z_{t}^{N, \varepsilon}\right|$ is bounded by $C n^{b}$.

For $g_{N}$ we use the classical Lipschitz approximation

$$
g_{N}(x)=\inf \left\{g(u)+N|x-u| \mid u \in \mathbb{R}^{d}\right\}
$$

Proposition 4.10. We assume that (HXO) holds and $g$ is $\alpha$-Hölder. Then, there exists a constant $C$ such that

$$
e_{1}(N) \leqslant \frac{C}{n^{\frac{2 b \alpha}{1-\alpha}}}
$$

Proof. $\quad g_{N}$ is a $N$-Lipschitz function and $g_{N} \rightarrow g$ when $N \rightarrow+\infty$ uniformly on $\mathbb{R}^{d}$. More precisely, we have

$$
\left|g-g_{N}\right|_{\infty} \leqslant \frac{C}{N^{\frac{\alpha}{1-\alpha}}}
$$

Remark 4.11. For some explicit examples, it is possible to have a better convergence speed. For example, let us take $g(x)=\left(|x|^{\alpha} \mathbb{1}_{x \geqslant 0}\right) \wedge C$ and assume that $\sigma$ is invertible. Then, we can use the fact that this function is not Lipschitz only in 0, and obtain

$$
e_{1}(N) \leqslant \frac{C}{n^{\frac{2 \alpha b}{1-\alpha}}} \mathbb{P}\left(X_{T} \in\left[0, N^{\frac{-1}{1-\alpha}}\right]\right)^{1 / q} \leqslant \frac{C}{n^{\frac{b}{1-\alpha}\left(2 \alpha+\frac{1}{q}\right)}}
$$

Remark 4.12. It is also possible to obtain convergence speed when $g$ is not $\alpha$-Hölder. For example, we assume that $\sigma$ is invertible and we set $g(x)=\prod_{i=1}^{d} \mathbb{1}_{x_{i}>0}(x)$. Then

$$
e_{1}(N) \leqslant C\left[\sum_{i=1}^{d} \mathbb{P}\left(\left(X_{T}\right)_{i} \in[0,1 / N]\right)\right]^{1 / q} \leqslant \frac{C}{N^{1 / q}}=\frac{C}{n^{b / q}}
$$

Now we are able to gather all these errors.
Theorem 4.13. We assume that (HX0), (HY0), (HY1), and (HX1) or (HX1') hold. We assume also that $g$ is $\alpha$-Hölder. Then for all $\eta>0$, there exists a constant $C>0$ that does not depend on $n$ such that

$$
e(n):=e(N, \varepsilon, n) \leqslant \frac{C}{n^{\frac{2 \alpha}{(2-\alpha)(2+K)-2+2 \alpha}}}
$$

with $K=4(1+\eta) L_{f, z}^{2} M_{z, 2}^{2}$.
Proof. Thanks to Theorem 4.8, Proposition 4.9 and Proposition 4.10 we have

$$
e(n) \leqslant \frac{C}{n^{1-2 b-K a}}+\frac{C}{n^{2 a-4 b}}+\frac{C}{n^{\frac{2 \alpha b}{1-\alpha}}}
$$

Then we only need to set $a:=\frac{1+2 b}{2+K}$ and $b:=\frac{1-\alpha}{(2-\alpha)(2+K)-2+2 \alpha}$ to obtain the result.
Corollary 4.14. We assume that assumptions of Theorem 4.13 hold. Moreover we assume that $f$ has a sub-quadratic growth with respect to $z$ : there exists $0<\beta<1$ such that, for all $t \in[0, T], x \in \mathbb{R}^{d}$, $y \in R, z, z^{\prime} \in \mathbb{R}^{1 \times d}$,

$$
\left|f(t, x, y, z)-f\left(t, x, y, z^{\prime}\right)\right| \leqslant\left(K_{f, z}+L_{f, z}\left(|z|^{\beta}+\left|z^{\prime}\right|^{\beta}\right)\right)\left|z-z^{\prime}\right|
$$

Then we are allowed to take $K$ as small as we want. So, for all $\eta>0$, there exists a constant $C>0$ that does not depend on $n$ such that

$$
e(n) \leqslant \frac{C}{n^{\alpha-\eta}}
$$

Remark 4.15. We are able to specify Remark 4.7 in our case, when $a=\frac{1+2 b}{2+K}$ and $b=\frac{1-\alpha}{(2-\alpha)(2+K)-2+2 \alpha}$.

- When $K \leqslant \frac{2-3 \alpha}{2-\alpha}$, that is to say, when $\alpha<2 / 3$ and $K$ is sufficiently small, then we do not need to have a discretization grid on $[T-\varepsilon, T]$.
- When $K>\frac{2-3 \alpha}{2-\alpha}$, then it is possible to take only $\left\lceil n^{c}\right\rceil$ discretization points on $[T-\varepsilon, T]$ with

$$
c=1+\frac{3 \alpha-4}{(2-\alpha)(2+K)-2+2 \alpha} .
$$

Theorem 4.13 is not interesting in practice because the speed of convergence depends strongly on $K$. But, we just see that the global error becomes $e(n) \leqslant \frac{C}{n^{\alpha-\eta}}$ when we are allowed to choose $K$ as small as we want. Under extra assumption we can show that we are allowed to take the constant $M_{z, 2}$ as small as we want.
(HX2). $\quad b$ is bounded on $[0, T] \times \mathbb{R}^{d}$ by a constant $M_{b}$.
Theorem 4.16. We assume that (HXO), (HYO), (HY1), (HX2) and (HX1) or (HX1') hold. We assume also that $g$ is $\alpha$-Hölder. Then for all $\eta>0$, there exists a constant $C>0$ that does not depend on $n$ such that

$$
e(n) \leqslant \frac{C}{n^{\alpha-\eta}} .
$$

Remark 4.17. With the assumptions of the previous theorem, it is also possible to have an estimate of the global error for examples given in Remarks 4.11 and 4.12. When $g(x)=\left(|x|^{\alpha} \mathbb{1}_{x \geqslant 0}\right) \wedge C$, we have

$$
e(n) \leqslant \frac{C}{n^{\alpha+\frac{1-\alpha}{1+2 q}-\eta}},
$$

and when $g(x)=\prod_{i=1}^{d} \mathbb{1}_{x_{i}>0}(x)$, we have

$$
e(n) \leqslant \frac{C}{n^{\frac{1}{1+2 q}-\eta}} .
$$

Proof. Firstly, we suppose that $f$ is differentiable with respect to $z$. Thanks to Remark 3.3 we see that it is sufficient to show that

$$
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s \mid \mathcal{F}_{t}\right]
$$

is small uniformly in $\omega, N$ and $\varepsilon$ when $t$ is close to $T$. We will obtain an estimation for this quantity by applying the same computation as [ 2 ] for the BMO norm estimate of $Z$ page 831. Thus we have

$$
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s \mid \mathcal{F}_{t}\right] \leqslant \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|\varphi\left(Y_{T}^{N, \varepsilon}\right)-\varphi\left(Y_{t}^{N, \varepsilon}\right)\right| \mid \mathcal{F}_{t}\right]+C(T-t),
$$

with $\varphi(x)=\left(e^{2 c(x+m)}-2 c(x+m)-1\right) /\left(2 c^{2}\right), m=|Y|_{\infty}$ and $c$ that depends on constants in assumption (HY0) but does not depend on $\nabla_{z} f$. Let us notice that $m, c$ and so $\varphi$ do not depend on $N$ and $\varepsilon$. Since $Y$ is bounded, $\varphi$ is a Lipschitz function, so

$$
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s \mid \mathcal{F}_{t}\right] \leqslant C \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|Y_{T}^{N, \varepsilon}-Y_{t}^{N, \varepsilon}\right| \mid \mathcal{F}_{t}\right]+C(T-t) .
$$

We denote by $\left(Y^{N, \varepsilon, t, x}, Z^{N, \varepsilon, t, x}\right)$ the solution of BSDE (4.1) when $X_{t}^{t, x}=x$. As usual, we set $X_{s}^{t, x}=x$ and $Z_{s}^{N, \varepsilon, t, x}=0$ for $s \leqslant t$ and we define $u^{N, \varepsilon}(t, x):=Y_{t}^{N, \varepsilon, t, x}$. Then we give a proposition that we will prove in the appendix.

Proposition 4.18. We assume that (HXO), (HYO), (HY1), (HX2) and (HX1) or (HX1') hold. We assume also that $g$ is uniformly continuous on $\mathbb{R}^{d}$. Then $u^{N, \varepsilon}$ is uniformly continuous on $[0, T] \times \mathbb{R}^{d}$ and there exists $\omega$ a concave modulus of continuity for all functions in $\left\{u^{N, \varepsilon} \mid N \in \mathbb{N}, \varepsilon>0\right\}$ : i.e. $\omega$ does not depend on $N$ and $\varepsilon$.

Then

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|Y_{T}^{N, \varepsilon}-Y_{t}^{N, \varepsilon}\right| \mid \mathcal{F}_{t}\right]= & \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|u^{N, \varepsilon}\left(T, X_{T}\right)-u^{N, \varepsilon}\left(t, X_{t}\right)\right| \mathcal{F}_{t}\right] \\
\leqslant & \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \leqslant \nu}\left|u^{N, \varepsilon}\left(T, X_{T}\right)-u^{N, \varepsilon}\left(t, X_{t}\right)\right|\right. \\
& \left.+2\left|Y^{N, \varepsilon}\right|_{\infty} \mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right|>\nu} \mid \mathcal{F}_{t}\right] \\
\leqslant & \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\omega\left(|T-t|+\mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \leqslant \nu}\left|X_{T}-X_{t}\right|\right)\right. \\
& \left.+2\left|Y^{N, \varepsilon}\right|_{\infty} \mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right|>\nu} \mid \mathcal{F}_{t}\right],
\end{aligned}
$$

with $d \tilde{W}_{s}=d W_{s}-\nabla_{z} f^{\varepsilon}\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right) d s$. But,

$$
\begin{aligned}
& \mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \leqslant \nu}\left|X_{T}-X_{t}\right| \\
= & \mathbb{1}_{\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \leqslant \nu}\left|\int_{t}^{T} b\left(s, X_{s}\right) d s+\int_{t}^{T} \nabla_{z} f^{\varepsilon}\left(s, X_{s}, Y_{s}^{N, \varepsilon}, Z_{s}^{N, \varepsilon}\right) d s+\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \\
\leqslant & M_{b}(T-t)+\nu+C \int_{t}^{T}\left(1+\left|Z_{s}^{N, \varepsilon}\right|\right) d s \\
\leqslant & C(T-t)+\nu+C(T-t)^{1 / 2}\left(\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s\right)^{1 / 2} .
\end{aligned}
$$

Since $\omega$ is concave, we have by Jensen's inequality

$$
\begin{aligned}
& \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\omega\left(|T-t|+\mathbb{1}_{\left|S_{t}^{T} \sigma(s) d \tilde{W}_{s}\right| \leqslant \nu}\left|X_{T}-X_{t}\right|\right) \mid \mathcal{F}_{t}\right] \\
\leqslant & \omega\left(C|T-t|+\nu+C(T-t)^{1 / 2} \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left(\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s\right)^{1 / 2} \mid \mathcal{F}_{t}\right]\right) \\
\leqslant & \omega\left(C|T-t|+\nu+C(T-t)^{1 / 2} \mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\int_{t}^{T}\left|Z_{s}^{N, \varepsilon}\right|^{2} d s \mid \mathcal{F}_{t}\right]^{1 / 2}\right) \\
\leqslant & \omega\left(C|T-t|+\nu+C(T-t)^{1 / 2}\left\|Z^{N, \varepsilon}\right\|_{B M O(\mathbb{Q})}\right) .
\end{aligned}
$$

But, $\left\|Z^{N, \varepsilon}\right\|_{B M O(\mathbb{Q})}$ only depends on constants in assumption (HY0), so it is bounded uniformly in $N$ and $\varepsilon$. Moreover, $\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right|$ is independent of $\mathcal{F}_{t}$ so we have by the Markov inequality

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\mathbb{1}_{\left|S_{t}^{T} \sigma(s) d \tilde{W}_{s}\right|>\nu} \mid \mathcal{F}_{t}\right] & =\mathbb{Q}^{N, \varepsilon}\left(\left|\int_{t}^{T} \sigma(s) d \tilde{W}_{s}\right|>\nu\right) \\
& \leqslant \frac{C(T-t)^{1 / 2}}{\nu}
\end{aligned}
$$

Finally, we have

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|Y_{T}^{N, \varepsilon}-Y_{t}^{N, \varepsilon}\right| \mid \mathcal{F}_{t}\right] & \leqslant \omega\left(C|T-t|^{1 / 2}+\nu\right)+C \frac{(T-t)^{1 / 2}}{\nu} \\
& \leqslant \omega\left(C|T-t|^{1 / 2}+|T-t|^{1 / 4}\right)+C|T-t|^{1 / 4}
\end{aligned}
$$

by setting $\nu=|T-t|^{1 / 4}$, and $\mathbb{E}^{\mathbb{Q}^{N, \varepsilon}}\left[\left|Y_{T}^{N, \varepsilon}-Y_{t}^{N, \varepsilon}\right| \mid \mathcal{F}_{t}\right] \rightarrow 0$ uniformly in $\omega, N$ and $\varepsilon$ when $t \rightarrow T$. When $f$ is not differentiable with respect to $z$ but is only locally Lipschitz then we can prove the result by a standard approximation.

## 5 Some additional results on the time dependent estimate of $Z$.

### 5.1 What happens if $\sigma$ does not depend on time?

We have seen that the key point of our approximation results is the time dependent estimate of $Z$ in Theorem 3.2. This estimate needs the technical assumption (HX1). When $\sigma$ does not depend on time, this assumption becomes
(HX1). $b$ is differentiable with respect to $x$ and there exists $\lambda \in \mathbb{R}^{+}$such that for all $\eta \in \mathbb{R}^{d}$

$$
\begin{equation*}
\left|{ }^{t} \eta \sigma^{t} \sigma^{t} \nabla b(s, x) \eta\right| \leqslant\left.\left.\lambda\right|^{t} \eta \sigma\right|^{2} . \tag{5.1}
\end{equation*}
$$

It is possible to obtain some equivalent assumptions.
Proposition 5.1. Let us assume that (HXO) hold, $b$ is differentiable with respect to $x$ and $\sigma$ does not depend on time. Then, following assertions are equivalent:
(i) $\forall x \in \mathbb{R}^{d}, \forall s \in[0, T], \operatorname{Im} \nabla b(s, x) \sigma \subset \operatorname{Im} \sigma$,
(ii) $\forall x \in \mathbb{R}^{d}, \forall s \in[0, T]$, $\operatorname{ker}^{t} \sigma \subset \operatorname{ker}^{t} \sigma^{t} \nabla b(s, x)$,
(iii) $\exists f:[0, T] \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d \times d}$ bounded such that $\forall x \in \mathbb{R}^{d}, \forall s \in[0, T], \nabla b(s, x) \sigma=\sigma f(s, x)$,
(iv) there exist $A:[0, T] \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d \times d}$ and $B:[0, T] \rightarrow R^{d \times d}$ such that $A$ is differentiable with respect to $x, \nabla A$ is bounded and $\forall x \in \mathbb{R}^{d}, \forall s \in[0, T], b(s, x) \sigma=\sigma A(s, x)+B(s)$,
(v) there exists $\lambda \in \mathbb{R}^{+}$such that $\forall \eta \in \mathbb{R}^{d}$

$$
\begin{equation*}
\left|{ }^{t} \eta \sigma^{t} \sigma^{t} \nabla b(s, x) \eta\right| \leqslant\left.\left.\lambda\right|^{t} \eta \sigma\right|^{2} . \tag{5.2}
\end{equation*}
$$

## Proof.

(iii) $\Rightarrow$ (i), (iii) $\Rightarrow$ (ii), (iii) $\Rightarrow$ (v) and (iii) $\Leftrightarrow$ (iv): Trivial.
(i) $\Rightarrow$ (iii): There exists $\tilde{\sigma}$ such that $\sigma \tilde{\sigma}_{\mid \operatorname{Im} \sigma}=I d_{\mid \operatorname{Im} \sigma}$. Since $\operatorname{Im} \nabla b(s, x) \sigma \subset \operatorname{Im} \sigma$ then $\nabla b(s, x) \sigma=$ $\sigma \tilde{\sigma} \nabla b(s, x) \sigma:=\sigma f(s, x) . \nabla b$ is bounded so $f$ is also bounded.
(ii) $\Rightarrow$ (iii): The proof is the same when we notice that there exists $\tilde{\sigma}$ such that $\tilde{\sigma} \sigma_{\mid M}=I d_{\mid M}$ with $M \oplus \operatorname{ker} \sigma=\mathbb{R}^{d}$.
(v) $\Rightarrow$ (ii): Let $S_{d}^{+}(\mathbb{R})$ denote the space of non negative symmetric matrix. Since $\sigma^{t} \sigma \in S_{d}^{+}(\mathbb{R})$, there exists $s \in S_{d}^{+}(\mathbb{R})$ such that $\sigma^{t} \sigma=s^{2}$. It is easy to show that $\operatorname{ker} s=\operatorname{ker}^{t} \sigma$ and $\operatorname{ker} s^{t} \nabla b(s, x)=$ ker ${ }^{t} \sigma^{t} \nabla b(s, x)$. Moreover, $\forall \eta \in \mathbb{R}^{d}$ and $\left|{ }^{t} \eta \sigma\right|^{2}=\left|{ }^{t} \eta s\right|^{2}$, so we are allowed to assume that $\sigma \in S_{d}^{+}(\mathbb{R})$.
If $\sigma$ is invertible or $\sigma=0$, the result is proved. Otherwise, let us consider $\eta_{1}$ and $\eta_{2}$ two eigenvectors of $\sigma$ linked with eigenvalues $\lambda_{1} \neq 0$ and $\lambda_{2}=0$. (v) gives us, for all $\alpha \in \mathbb{R}$,

$$
\begin{aligned}
\left.\right|^{t}\left(\eta_{1}+\alpha \eta_{2}\right) \sigma^{2 t} \nabla b(s, x)\left(\eta_{1}+\alpha \eta_{2}\right) \mid & =\left|\lambda_{1}^{2 t} \eta_{1}^{t} \nabla b(s, x) \eta_{1}+\alpha \lambda_{1}^{2 t} \eta_{1}^{t} \nabla b(s, x) \eta_{2}\right| \\
& \leqslant \lambda \lambda_{1}^{2}\left|\eta_{1}\right|^{2} .
\end{aligned}
$$

$\left.\right|^{t}\left(\eta_{1}+\alpha \eta_{2}\right) \sigma^{2 t} \nabla b(s, x)\left(\eta_{1}+\alpha \eta_{2}\right) \mid$ is bounded with respect to $\alpha$, implying ${ }^{t} \eta_{1}{ }^{t} \nabla b(s, x) \eta_{2}=0$.
Since $\sigma \in S_{d}^{+}(\mathbb{R})$, we have $\operatorname{ker} \sigma \stackrel{\perp}{\oplus} \operatorname{Im} \sigma$. So, for all $\eta_{2} \in \operatorname{ker} \sigma$, we have shown ${ }^{t} \nabla b(s, x) \eta_{2} \in$ $(\operatorname{Im} \sigma)^{\perp}=\operatorname{ker} \sigma$, that is to say, $\sigma^{t} \nabla b(s, x) \eta_{2}=0$. This last equality allow us to conclude that $\operatorname{ker} \sigma \subset \operatorname{ker} \sigma^{t} \nabla b(s, x)$.

The assertion (v) allows us to reduce assumptions on the regularity of $b$. Indeed, when $A$ is only a Lipschitz function with respect to $x$ with a Lipschitz constant $K_{A}$, then it is possible to do a classical approximation of $A$ by a sequence of differentiable functions $\left(A_{n}\right)_{n \in \mathbb{N}}$ such that $\left|\nabla A_{n}(s, x)\right| \leqslant K_{A}$.
(HX1"). $\quad \sigma$ does not depend on time. There exist $A:[0, T] \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d \times d}$ and $B:[0, T] \rightarrow R^{d \times d}$ such that $\forall x \in \mathbb{R}^{d}, \forall s \in[0, T], b(s, x) \sigma=\sigma A(s, x)+B(s)$.

Then we obtain a new version of Theorem 3.2.
Theorem 5.2. Suppose that (HXO), (HYO) and (HX1") hold. Moreover, suppose that $g$ is lower (or upper) semi-continuous. Then there exists a version of $Z$ and there exist two constants $C, C^{\prime} \in \mathbb{R}^{+}$that depend only in $T, M_{g}, M_{f}, K_{f, x}, K_{f, y}, K_{f, z}$ and $L_{f, z}$ such that, $\forall t \in[0, T[$,

$$
\left|Z_{t}\right| \leqslant C+C^{\prime}(T-t)^{-1 / 2} .
$$

### 5.2 Some examples and counterexamples.

As we already explain in the introduction, Theorem 3.2 is also interesting for BSDEs with a linear growth with respect to $z$. Indeed, such an estimation has been already proved when $\sigma$ is invertible by using the Bismut-Elworthy formula, see e.g. [10], while in our case we do not need to assume the invertibility of $\sigma$. Nevertheless, technical assumptions (HX1) or (HX1") appear. Let us see what could happen when these assumptions do not hold. The most simple counterexample is given by Zhang in [2]]. Let us consider our SDE in dimension 1. We take:

- $T=2$,
- $b=0$,
- $\forall t \in[0,2], \sigma(t)=(1-t) \mathbb{1}_{t<1}$,
- $f=0$,
- $\forall x \in \mathbb{R}, g(x)=\arctan \left(\frac{x}{|x|^{3 / 4}}\right)$.

Proposition 5.3. $\forall M>0, \exists 0 \leqslant t_{1}<t_{2}<1, \mathbb{P}\left(\left|Z_{\mid\left[t_{1}, t_{2}\right]}\right| \geqslant M\right)>0$.
Proof. Let us denote $u(t, x):=Y_{t}^{t, x}$ with $\left(Y_{t}^{t, x}, Z_{t}^{t, x}\right)$ the solution of the BSDE (2.2) where $X$ verifies $X_{t}=x$. For $t \in[1,2]$, obviously $u(t, x)=g(x)$ and $Z_{t}^{t, x}=0$. For $t \in[0,1[$, we have

$$
\begin{aligned}
u(t, x) & =\mathbb{E}\left[g\left(x+\int_{t}^{1}(1-s) d W_{s}\right)\right] \\
& =\frac{1}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} g(y) \exp \left(-\frac{(y-x)^{2}}{2 \sigma_{t}^{2}}\right) d y,
\end{aligned}
$$

with $\sigma_{t}^{2}=\int_{t}^{1}(1-s)^{2} d s=\frac{1}{3}(1-t)^{3}$. Moreover,

$$
\begin{equation*}
\nabla u(t, x)=\frac{1}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} g(y) \frac{(y-x)}{\sigma_{t}^{2}} \exp \left(-\frac{(y-x)^{2}}{2 \sigma_{t}^{2}}\right) d y . \tag{5.3}
\end{equation*}
$$

By using the substitution $y=\sigma_{t} z$, we get

$$
\begin{aligned}
\nabla u(t, 0) & =\frac{1}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} g\left(\sigma_{t} z\right) z \exp \left(-\frac{z^{2}}{2}\right) d z \\
& =\frac{\sigma_{t}^{1 / 4}}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} \frac{1}{\sigma_{t}^{1 / 4}} \arctan \left(\sigma_{t}^{1 / 4} \frac{z}{|z|^{3 / 4}}\right) z \exp \left(-\frac{z^{2}}{2}\right) d y .
\end{aligned}
$$

By dominated convergence theorem we have

$$
\int_{\mathbb{R}} \frac{1}{\sigma_{t}^{1 / 4}} \arctan \left(\sigma_{t}^{1 / 4} \frac{z}{|z|^{3 / 4}}\right) z \exp \left(-\frac{z^{2}}{2}\right) d y \xrightarrow{t \rightarrow 1^{-}} \int_{\mathbb{R}}|z|^{2-3 / 4} \exp \left(-\frac{z^{2}}{2}\right) d y>0 .
$$

So,

$$
\nabla u(t, 0) \sigma(t) \stackrel{t \rightarrow 1^{-}}{\sim} \frac{C(1-t)}{\sigma_{t}^{3 / 4}}=\frac{C}{(1-t)^{1 / 8}} \xrightarrow{t \rightarrow 1^{-}}+\infty .
$$

Moreover, the equation (5.3) allows us to show that $(t, x) \mapsto \nabla u(t, x)$ is continuous on $[0,1[\times \mathbb{R}$. So, for all $M>0, \exists\left[t_{1}, t_{2}\right] \subset\left[0,1\left[\right.\right.$ with $t_{1}<t_{2}, \exists \varepsilon>0$, such that $\forall x \in[-\varepsilon, \varepsilon], \forall t \in\left[t_{1}, t_{2}\right]$ we have $|\nabla u(t, x) \sigma(t)| \geqslant M$. Since $Z_{t}=Z_{t}^{t, X_{t}^{x}}=\nabla u\left(t, X_{t}^{x}\right) \sigma(t)$, then

$$
\mathbb{P}\left(\left|Z_{\mid\left[t_{1}, t_{2}\right]}\right| \geqslant M\right) \geqslant \mathbb{P}\left(\left|X_{\left[t_{1}, t_{2}\right]}^{x}\right| \leqslant \varepsilon\right)>0 .
$$

To construct this example, the idea is to stop the noise after the time $t=1$ to obtain no random evolution in the time interval $[1,2]$. In this example we need to have a function $\sigma$ that depends on time. Let us see if it is possible to construct a counterexample when we are not in this situation. If we suppose that (HX0) holds, then the assumption (HX1") is always true in dimension 1 . So we will take $d=2$ and

- $T=2$,
- $\forall t \in[0,2], \forall x=\left(x^{1}, x^{2}\right) \in \mathbb{R}^{2}, b(t, x)=\binom{0}{h(t) x^{1}}$,
- $\forall t \in[0,2], \sigma(t)=\left(\begin{array}{ll}1 & 0 \\ 0 & 0\end{array}\right)$,
- $f=0$

With these functions, (HX1) does not hold when $h \neq 0$. The solution of the SDE is

$$
\begin{aligned}
& X_{t}^{1}=x^{1}+W_{t}^{1} \\
& X_{t}^{2}=x^{2}+x^{1} \int_{0}^{t} h(s) d s+\int_{0}^{t} h(s) W_{s}^{1} d s
\end{aligned}
$$

As we try to obtain an explosion at time $t=1$, we will take for $h$ a continuous function such that $h_{[0,1[ }>0$ and $h_{\mid[1,2]}=0$. Moreover, we assume that $\forall x=\left(x^{1}, x^{2}\right) \in \mathbb{R}^{2}, g(x)=\tilde{g}\left(x^{2}\right)$ with $\tilde{g}: \mathbb{R} \rightarrow \mathbb{R}$ a bounded lower (or upper) semi-continuous function. As before, we denote $u(t, x):=Y_{t}^{t, x}$ with $\left(Y_{t}^{t, x}, Z_{t}^{t, x}\right)$ the solution of the BSDE (2.2) where $X$ verifies $X_{t}=x$. For $t \in[1,2]$, obviously $u(t, x)=g(x)=\tilde{g}\left(x^{2}\right)$ and $Z_{t}^{t, x}=0$. For $t \in[0,1[$, we have

$$
u(t, x)=\mathbb{E}\left[\tilde{g}\left(x^{2}+x^{1} \int_{t}^{1} h(s) d s+\int_{t}^{1} h(s) W_{s}^{1} d s\right)\right] .
$$

Let us denote $H$ a primitive of $h$. Then,

$$
\begin{aligned}
\int_{t}^{1} h(s) W_{s}^{1} d s & =H(1) W_{1}^{1}-H(t) W_{t}^{1}-\int_{t}^{1} H(s) d W_{s}^{1} \\
& =[H(1)-H(t)] W_{t}^{1}+\int_{t}^{1}[H(1)-H(s)] d W_{s}^{1}
\end{aligned}
$$

So,

$$
u(t, x)=\frac{1}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} \tilde{g}(y) \exp \left(-\frac{\left(y-x^{2}-a_{t} x^{1}\right)^{2}}{2 \sigma_{t}^{2}}\right) d y
$$

with $\sigma_{t}^{2}=[H(1)-H(t)]^{2} t+\int_{t}^{1}[H(1)-H(s)]^{2} d s$ and $a_{t}=[H(1)-H(t)]$. Moreover,

$$
Z_{t}=\nabla u\left(t, X_{t}\right) \sigma=\frac{\partial u}{\partial x^{1}}\left(t, X_{t}\right)
$$

and

$$
\frac{\partial u}{\partial x^{1}}(t, x)=\frac{a_{t}}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} \tilde{g}(y) \frac{\left(y-x^{2}-a_{t} x^{1}\right)}{\sigma_{t}^{2}} \exp \left(-\frac{\left(y-x^{2}-a_{t} x^{1}\right)^{2}}{2 \sigma_{t}^{2}}\right) d y
$$

So, By using the substitution $y-x^{2}-a_{t} x^{1}=\sigma_{t} z$, we get

$$
\frac{\partial u}{\partial x^{1}}(t, x)=\frac{a_{t}}{\sqrt{2 \pi} \sigma_{t}} \int_{\mathbb{R}} \tilde{g}\left(\sigma_{t} z+x^{2}+a_{t} x^{1}\right) z \exp \left(-\frac{z^{2}}{2}\right) d z
$$

and

$$
\left|\frac{\partial u}{\partial x^{1}}(t, x)\right| \leqslant C \frac{\left|a_{t}\right|}{\sigma_{t}} \int_{\mathbb{R}}|z| \exp \left(-\frac{z^{2}}{2}\right) d z \leqslant C
$$

because $\left|a_{t}\right| \leqslant \sigma_{t}$. Finally, we obtain that $Z$ is bounded on the interval $[0,2]$ even if we it is possible to show that $\frac{\partial u}{\partial x^{2}}(t, 0) \xrightarrow{t \rightarrow 1^{-}}+\infty$ for well-chosen functions $\tilde{g}$ and $h$. This example proves that (HX1") is a not necessary but sufficient assumption. To be more precise, when $\sigma$ does not depend on time we do not succeed to find an example of BSDE such that we have not the estimate

$$
Z_{t} \leqslant C+C^{\prime}(T-t)^{-1 / 2}
$$

So, the assumption (HX1") seems to be artificially restrictive and unnecessary. But this question remains open.

## 6 Appendix

### 6.1 Proof of Lemma 4.3.

We have,

$$
\prod_{i=0}^{2 n-1}\left(1+M h_{i}\right)=\left(\prod_{i=0}^{n-1}\left(1+M h_{i}\right)\right)\left(\prod_{i=n}^{2 n-1}\left(1+M h_{i}\right)\right)
$$

Firstly,

$$
\prod_{i=n}^{2 n-1}\left(1+M h_{i}\right) \leqslant\left(1+M \frac{T}{n}\right)^{n} \leqslant C
$$

Moreover, for $0 \leqslant i \leqslant n-1$,

$$
h_{i}=t_{i+1}-t_{i}=T n^{-a i / n}\left(1-e^{-\frac{a \ln n}{n}}\right) \leqslant T n^{-a i / n} a \frac{\ln n}{n}
$$

${ }^{3}$ Take for example $h(s)=(1-s) \mathbb{1}_{s<1}$ and $\tilde{g}(x)=\arctan \left(\frac{x}{|x|^{1 / 2}}\right)$.
thanks to the convexity of the exponential function. So

$$
\begin{aligned}
\prod_{i=0}^{n-1}\left(1+M h_{i}\right) & \leqslant \prod_{i=0}^{n-1}\left(1+M \operatorname{Tan}^{-a i / n} \frac{\ln n}{n}\right) \\
& =\exp \left(\sum_{i=0}^{n-1} \ln \left(1+M \operatorname{Tan}^{-a i / n} \frac{\ln n}{n}\right)\right) \\
& \leqslant \exp \left(\sum_{i=0}^{n-1} M T a\left(n^{-a / n}\right)^{i} \frac{\ln n}{n}\right) \\
& \leqslant \exp \left(M T a \frac{\ln n}{n}\left(\frac{1-\left(1 / n^{a}\right)}{1-\left(1 / n^{(a / n)}\right)}\right)\right) \\
& \leqslant \exp \left(M T a \frac{\ln n}{n} \frac{n^{a / n}}{n^{a / n}-1}\right)
\end{aligned}
$$

But,

$$
\frac{\ln n}{n} \frac{n^{a / n}}{n^{a / n}-1} \sim \frac{\ln n}{n} \frac{1}{a \frac{\ln n}{n}} \sim \frac{1}{a}
$$

when $n \rightarrow+\infty$. Thus, we have shown the result.

### 6.2 Proof of Lemma 4.4.

Thanks to Lemma 4.3, we have

$$
\frac{\prod_{i=0}^{n-1}\left(1+M_{1} h_{i}+M_{2} \frac{h_{i}}{T-t_{i+1}}\right)}{\prod_{i=0}^{n-1}\left(1+M_{2} \frac{h_{i}}{T-t_{i+1}}\right)}=\prod_{i=0}^{n-1}\left(1+\frac{M_{1}}{1+M_{2} \frac{h_{i}}{T-t_{i+1}}} h_{i}\right) \leqslant \prod_{i=0}^{n-1}\left(1+M_{1} h_{i}\right) \leqslant C
$$

So, we just have to show that

$$
\prod_{i=0}^{n-1}\left(1+M_{2} \frac{h_{i}}{T-t_{i+1}}\right) \leqslant C n^{a M_{2}}
$$

But,

$$
1+M_{2} \frac{h_{i}}{T-t_{i+1}}=1+M_{2}\left(n^{a / n}-1\right)
$$

So,

$$
\begin{aligned}
\prod_{i=0}^{n-1}\left(1+M_{2} \frac{h_{i}}{T-t_{i+1}}\right) & =\left(1+M_{2}\left(n^{a / n}-1\right)\right)^{n} \\
& =\exp \left(n \ln \left(1+a M_{2} \frac{\ln n}{n}+O\left(\frac{\ln ^{2} n}{n^{2}}\right)\right)\right) \\
& =\exp \left(a M_{2} \ln n+O\left(\frac{\ln ^{2} n}{n}\right)\right) \sim n^{a M_{2}}
\end{aligned}
$$

when $n \rightarrow+\infty$. Thus, we have shown the result.

### 6.3 Proof of Proposition 4.18.

We will prove this proposition as the authors of [9] do for their Proposition 4.2. In all the proof we omit the superscript $N, \varepsilon$ for $u, Y$ and $Z$ to be more readable. Let $x_{0}, x_{0}^{\prime} \in \mathbb{R}^{d}$ and $t_{0}, t_{0}^{\prime} \in[0, T]$. By an argument of symmetry we are allowed to suppose that $t_{0} \leqslant t_{0}^{\prime}$. We have

$$
\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}^{\prime}, x_{0}^{\prime}\right)\right| \leqslant\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}, x_{0}^{\prime}\right)\right|+\left|u\left(t_{0}, x_{0}^{\prime}\right)-u\left(t_{0}^{\prime}, x_{0}^{\prime}\right)\right|
$$

Let us begin with the first term. We will use a classical argument of linearization:

$$
\begin{aligned}
Y_{t}^{t_{0}, x_{0}}-Y_{t}^{t_{0}, x_{0}^{\prime}}= & g_{N}\left(X_{T}^{t_{0}, x_{0}}\right)-g_{N}\left(X_{T}^{t_{0}, x_{0}^{\prime}}\right)+\int_{t}^{T} \alpha_{s}\left(X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}}\right)+\beta_{s}\left(Y_{s}^{t_{0}, x_{0}}-Y_{s}^{t_{0}, x_{0}^{\prime}}\right) d s \\
& -\int_{t}^{T}\left(Z_{s}^{t_{0}, x_{0}}-Z_{s}^{t_{0}, x_{0}^{\prime}}\right) d \tilde{W}_{s}
\end{aligned}
$$

with

$$
\begin{aligned}
& \alpha_{s}=\left\{\begin{array}{cl}
\frac{f^{\varepsilon}\left(s, X_{s}^{t_{0}, x_{0}}, Y_{s}^{t_{0}, x_{0}^{\prime}}, Z_{s}^{t_{0}, x_{0}^{\prime}}\right)-f^{\varepsilon}\left(s, X_{s}^{t_{0}, x_{0}^{\prime}}, Y_{s}^{t_{0}, x_{0}^{\prime}}, Z_{s}^{t_{0}, x_{0}^{\prime}}\right)}{X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}}} & \text { if } X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}} \neq 0, \\
0 & \text { elsewhere, }
\end{array}\right. \\
& \beta_{s}=\left\{\begin{array}{cl}
\frac{f^{\varepsilon}\left(s, X_{s}^{t_{0}, x_{0}}, Y_{s}^{t_{0}, x_{0}}, Z_{s}^{t_{0}, x_{0}^{\prime}}\right)-f^{\varepsilon}\left(s, X_{s}^{t_{0}, x_{0}}, Y_{s}^{t_{0}, x_{0}^{\prime}}, Z_{s}^{t_{0}, x_{0}^{\prime}}\right)}{Y_{s}^{t_{0}, x_{0}}-Y_{s}^{t_{0}, x_{0}^{\prime}}} & \text { if } Y_{s}^{t_{0}, x_{0}}-Y_{s}^{t_{0}, x_{0}^{\prime}} \neq 0, \\
0 & \text { elsewhere },
\end{array}\right.
\end{aligned}
$$

and $d \tilde{W}_{s}:=d W_{s}-\gamma_{s} d s$. By a BMO argument, there exists a probability $\mathbb{Q}$ under which $\tilde{W}$ is a Brownian motion. Then we apply a classical transformation to obtain

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}}\left[e^{\int_{t_{0}}^{t} \beta_{s} d s}\left(Y_{t}^{t_{0}, x_{0}}-Y_{t}^{t_{0}, x_{0}^{\prime}}\right)\right]= & \mathbb{E}^{\mathbb{Q}}\left[e^{\int_{t_{0}}^{T} \beta_{s} d s}\left(g_{N}\left(X_{T}^{t_{0}, x_{0}}\right)-g_{N}\left(X_{T}^{t_{0}, x_{0}^{\prime}}\right)\right)\right. \\
& \left.+\int_{t_{0}}^{T} \alpha_{s} e^{\int_{t_{0}}^{s} \beta_{u} d u}\left(X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}}\right) d s\right]
\end{aligned}
$$

and

$$
\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}, x_{0}^{\prime}\right)\right| \leqslant C\left(\mathbb{E}^{\mathbb{Q}}\left[\omega\left(\left|X_{T}^{t_{0}, x_{0}}-X_{T}^{t_{0}, x_{0}^{\prime}}\right|\right)\right]+\int_{t_{0}}^{T} \mathbb{E}^{\mathbb{Q}}\left[\left|X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}}\right|\right] d s\right)
$$

with $\omega$ a modulus of continuity of $g$ that is also a modulus of continuity for $g_{N}$. We are allowed to suppose that $\omega$ is concave so Jensen's inequality gives us

$$
\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}, x_{0}^{\prime}\right)\right| \leqslant C\left(\omega\left(\mathbb{E}^{\mathbb{Q}}\left[\left|X_{T}^{t_{0}, x_{0}}-X_{T}^{t_{0}, x_{0}^{\prime}}\right|\right]\right)+\int_{t_{0}}^{T} \mathbb{E}^{\mathbb{Q}}\left[\left|X_{s}^{t_{0}, x_{0}}-X_{s}^{t_{0}, x_{0}^{\prime}}\right|\right] d s\right)
$$

By using the fact that $b$ is bounded we can prove the following proposition exactly as authors of [9] do for their Proposition 4.7:

[^2]Proposition 6.1. $\exists C>0$ that does not depend on $N$ and $\varepsilon$ such that $\forall t, t^{\prime} \in[0, T], \forall x, x^{\prime} \in \mathbb{R}^{d}$, $\forall s \in[0, T]$,

$$
\mathbb{E}^{\mathbb{Q}}\left[\left|X_{s}^{t, x}-X_{s}^{t^{\prime}, x^{\prime}}\right|\right] \leqslant C\left(\left|x-x^{\prime}\right|+\left|t-t^{\prime}\right|^{1 / 2}\right) .
$$

Then,

$$
\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}, x_{0}^{\prime}\right)\right| \leqslant C\left(\omega\left(\left|x_{0}-x_{0}^{\prime}\right|\right)+\left|x_{0}-x_{0}^{\prime}\right|\right) .
$$

Now we will study the second term:

$$
\left|u\left(t_{0}, x_{0}^{\prime}\right)-u\left(t_{0}^{\prime}, x_{0}^{\prime}\right)\right|=\left|Y_{t_{0}}^{t_{0}, x_{0}^{\prime}}-Y_{t_{0}^{\prime}}^{t_{0}^{\prime}, x_{0}^{\prime}}\right| \leqslant\left|Y_{t_{0}}^{t_{0}, x_{0}^{\prime}}-Y_{t_{0}}^{t_{0}^{\prime}, x_{0}^{\prime}}\right|+\left|Y_{t_{0}^{\prime}, x_{0}^{\prime}}^{t_{0}^{\prime}}-Y_{t_{0}^{\prime}}^{t_{0}^{\prime}, x_{0}^{\prime}}\right| .
$$

Firstly,

$$
\left|Y_{t_{0}}^{t_{0}^{\prime}, x_{0}^{\prime}}-Y_{t_{0}^{\prime}}^{t_{0}^{\prime}, x_{0}^{\prime}}\right| \leqslant\left|\int_{t_{0}}^{t_{0}^{\prime}} f\left(s, x_{0}^{\prime}, Y_{s}^{t_{0}^{\prime}, x_{0}^{\prime}}, 0\right) d s\right| \leqslant C\left|t_{0}-t_{0}^{\prime}\right| .
$$

Moreover, as for the first term we have

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}}\left[e^{\int_{t_{0}}^{t} \beta_{s} d s}\left(Y_{t}^{t_{0}, x_{0}^{\prime}}-Y_{t}^{t_{0}^{\prime}, x_{0}^{\prime}}\right)\right]= & \mathbb{E}^{\mathbb{Q}}\left[e^{\int_{t_{0}}^{T} \beta_{s} d s}\left(g_{N}\left(X_{T}^{t_{0}, x_{0}^{\prime}}\right)-g_{N}\left(X_{T}^{t_{0}^{\prime}, x_{0}^{\prime}}\right)\right)\right. \\
& \left.+\int_{t_{0}}^{T} \alpha_{s} e^{\int_{t_{0}}^{s} \beta_{u} d u}\left(X_{s}^{t_{0}, x_{0}^{\prime}}-X_{s}^{t_{0}^{\prime}, x_{0}^{\prime}}\right) d s\right],
\end{aligned}
$$

and

$$
\left|Y_{t_{0}}^{t_{0}, x_{0}^{\prime}}-Y_{t_{0}^{\prime}}^{t_{0}^{\prime}, x_{0}^{\prime}}\right| \leqslant C\left(\omega\left(\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right)+\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right)
$$

Finally,

$$
\left|u\left(t_{0}, x_{0}^{\prime}\right)-u\left(t_{0}^{\prime}, x_{0}^{\prime}\right)\right| \leqslant C\left(\omega\left(\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right)+\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right)
$$

and

$$
\left|u\left(t_{0}, x_{0}\right)-u\left(t_{0}^{\prime}, x_{0}^{\prime}\right)\right| \leqslant C\left(\omega\left(\left|x_{0}-x_{0}^{\prime}\right|\right)+\omega\left(\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right)+\left|x_{0}-x_{0}^{\prime}\right|+\left|t_{0}-t_{0}^{\prime}\right|^{1 / 2}\right) .
$$

So $u$ is uniformly continuous on $[0, T] \times \mathbb{R}^{d}$ and this function has a modulus of continuity that does not depend on $N$ and $\varepsilon$. Moreover, we are allowed to suppose that this modulus of continuity is concave.

[^0]:    ${ }^{1}$ Roughly speaking, the driver is a sum of a quadratic term $z \mapsto C|z|^{2}$ and a function that has a linear growth with respect to $z$.

[^1]:    ${ }^{2}$ The authors of 14 obtain this result with $q^{2}$ instead of $q$. Nevertheless, we are able to obtain the good result by applying the estimates of [2].

[^2]:    ${ }^{4}$ There exist two positive constants $a$ and $b$ such that $\omega(x) \leqslant a x+b$. Then the concave hull of $x \mapsto \omega(x) \vee\left(\mathbb{1}_{x \geqslant 1}(a x+b)\right)$ is a also a modulus of continuity of $g$.
