Abstract

Univariate and multivariate quadratic spline quasi-interpolants provide interesting approximation formulas for derivatives of approximated functions that can be very accurate at some points thanks to the superconvergence properties of these operators. Moreover, they also give rise to good global approximations of derivatives on the whole domain of definition. From these results, some collocation methods are deduced for the solution of ordinary or partial differential equations with boundary conditions. Their convergence properties are illustrated and compared with finite difference methods on some numerical examples of elliptic boundary value problems.

Key words: spline approximants, Numerical differentiation, spline collocation methods.

1991 MSC: 65D07, 65D25, 65N35

1 Introduction

Univariate and multivariate spline quasi-interpolants (abbr. QIs) have been studied for several decades in approximation theory (see e.g. [1a, 1c, 2, 8, 9a, 9b, 9c]). However, few studies have been devoted to their potential applications in numerical analysis. Such a program has already been initiated in [7a–b] where some applications to the approximation of derivatives have been developed. In this paper, we focus on approximations of first and second

derivatives by those of quadratic spline quasi-interpolants and their applications to collocation methods. Though it is possible to use spline QIs of higher degrees and smoothness, we want to show that already simple C^1 quadratic splines provide rather good numerical methods.

Let $I = [a, b]$ with the uniform partition $\mathcal{X}_n = \{x_i = a + ih, 0 \leq i \leq n\}$ where $h = (b - a)/n$, and $x_{-2} = a - 2h, x_{-1} = a - h, x_{n+1} = b + h, x_{n+2} = b + 2h$. For $1 \leq i \leq n$, let $t_i = \frac{1}{2}(x_{i-1} + x_i)$, $u_i = t_i - hr/6$, $v_i = t_i + hr/6$ (where $r := \sqrt{3}$), and let $t_0 = a, t_{n+1} = b, v_0 = a, u_{n+1} = b$. Let $J := \{0, 1, \dots, n+1\}$. On $\mathcal{T}_n := \{t_i, i \in J\}$ we define $f_i = f(t_i)$, $0 \leq i \leq n+1$, and on the set of Gauss abscissas $\mathcal{G}_n := \{v_0; u_i, v_i, 1 \leq i \leq n; u_{n+1}\}$, we define $\tilde{f}_i = f(u_i)$, $1 \leq i \leq n+1$ and $\hat{f}_i = f(v_i)$, $0 \leq i \leq n$. Quadratic B-splines $\{B_i, i \in J\}$, with supports $[x_{i-2}, x_{i+1}]$ form a basis of the $n+2$ -dimensional space $\mathcal{S}_2(I, \mathcal{X}_n)$ of C^1 quadratic splines (see e.g. [1b, 3, 10]).

In Section 2, we study the *uniform quadratic spline quasi-interpolant* (abbr. uniform QI) \bar{Q} , and the *Gauss quadratic spline quasi-interpolant* (abbr. Gauss QI) \tilde{Q} , respectively defined by

$$\bar{Q}f = \sum_{i \in J} \lambda_i(f) B_i \quad \text{and} \quad \tilde{Q}f = \sum_{i \in J} \mu_i(f) B_i,$$

where the coefficient functionals are given, for $2 \leq i \leq n-1$, by

$$\lambda_i(f) = \frac{1}{8}(-f_{i-1} + 10f_i - f_{i+1}) \quad \text{and} \quad \mu_i(f) = \alpha(\tilde{f}_i + \hat{f}_i) + \beta(\hat{f}_{i-1} + \tilde{f}_{i+1}),$$

with $\alpha = (9+r)/12$ and $\beta = -(3+r)/12$. For extreme indices, the functionals have specific forms (see Section 2 below). The uniform QI is based on the set \mathcal{X}_n and the Gauss QI is based on the set \mathcal{G}_n . The choice of coefficients implies that the two QIs are exact on \mathbb{P}_2 , i.e. $\bar{Q}m_s = \tilde{Q}m_s = m_s$ for $s = 0, 1, 2$, with the notation $m_s(x) := x^s$. This can be verified by using the B-spline representation of monomials. It implies in particular ([5], chapter 5), that the *global approximation error* $Qf - f$ on a smooth function f is $O(h^3)$.

However, we notice that $Qf(a) = f(a)$, $Qf(b) = f(b)$, $Qf(x_i) - f(x_i) = O(h^4)$, $1 \leq i \leq n-1$, and $Qf(t_i) - f(t_i) = O(h^4)$, $1 \leq i \leq n$, for both quasi-interpolants $Q = \bar{Q}$ or \tilde{Q} . Therefore there is a *superconvergence phenomenon* of these operators on the sets of points \mathcal{X}_n and \mathcal{T}_n . This phenomenon *does not hold* on \mathcal{G}_n . On the other hand, in Section 3, we show that *another superconvergence phenomenon* takes place at Gaussian points for *first derivatives*, which leads to an improvement of global approximation properties of these derivatives. Section 4 describes some *derivation matrices* which are used in Section 5 in collocation methods for the solution of some univariate Dirichlet problems. The numerical results show an improvement with respect to classical finite difference methods. Finally, Sections 6 and 7 give some bivariate extensions of previous methods and an application to the Dirichlet problem for the Laplace equation. Once again, the new method is better than finite difference methods for the Laplacian.

2 Univariate quadratic spline quasi-interpolants

2.1 Properties of the uniform quasi-interpolant

The specific coefficient functionals for extreme indices of the *uniform quadratic spline quasi-interpolant* $\bar{Q}f = \sum_{i \in J} \lambda_i(f)B_i$ are defined as follows :

$$\begin{aligned} \lambda_0(f) &:= \frac{12}{5}f_0 - \frac{13}{8}f_1 + \frac{1}{4}f_2 - \frac{1}{40}f_3, & \lambda_{n+1}(f) &:= \frac{12}{5}f_{n+1} - \frac{13}{8}f_n + \frac{1}{4}f_{n-1} - \frac{1}{40}f_{n-2}, \\ \lambda_1(f) &:= -\frac{2}{5}f_0 + \frac{13}{8}f_1 - \frac{1}{4}f_2 + \frac{1}{40}f_3, & \lambda_n(f) &:= -\frac{2}{5}f_{n+1} + \frac{13}{8}f_n - \frac{1}{4}f_{n-1} + \frac{1}{40}f_{n-2}. \end{aligned}$$

We notice that $\bar{Q}f(a) = (\lambda_0 + \lambda_1)/2 = f_0 = f(a)$ and $\bar{Q}f(b) = (\lambda_n + \lambda_{n+1})/2 = f_{n+1} = f(b)$, therefore $\bar{Q}f$ interpolates f at the extreme points of I . This QI can also be written in the *quasi-Lagrange form*

$$\bar{Q}f = \sum_{j \in J} f_j \bar{B}_j, \text{ with } \bar{B}_j := \frac{1}{8}(-B_{j-1} + 10B_j - B_{j+1}), \quad 4 \leq j \leq n-3.$$

The coefficients in the basis $\{B_i, i \in J\}$ of the first and last four *quasi-Lagrange functions* are given in the following table (with upper (resp. lower) indices for left (resp. right) functions).

i	0	1	2	3	4	
\bar{B}_0	12/5	-2/5	0	0	0	\bar{B}_{n+1}
\bar{B}_1	-13/8	13/8	-1/8	0	0	\bar{B}_n
\bar{B}_2	1/4	-1/4	5/4	-1/8	0	\bar{B}_{n-1}
\bar{B}_3	-1/40	1/40	-1/8	5/4	-1/8	\bar{B}_{n-2}
	$n+1$	n	$n-1$	$n-2$	$n-3$	i

Proposition 1. *The quasi-interpolant \bar{Q} is exact on the space \mathbb{P}_2 of quadratic polynomials, i.e. $\bar{Q}m_r = m_r$ for $r = 0, 1, 2$. Moreover $\|\bar{Q}\|_\infty = 3/2$.*

Proof: Let us give the proof for $\bar{Q}m_2 = m_2$. It is well known (see e.g. [1b]) that $m_2 = \sum_{j \in J} x_{j-1}x_j B_j$. Using $t_{j-1} = t_j - h$ and $t_{j+1} = t_j + h$, we obtain

$$\lambda_j(m_2) = \frac{1}{8}(-t_{j-1}^2 + 10t_j^2 - t_{j+1}^2) = t_j^2 - \frac{h^2}{4} = x_{j-1}x_j, \text{ for } 2 \leq j \leq n-1.$$

In the same way, one verifies that

$$\begin{aligned}\lambda_0(m_2) &= \frac{1}{40} \left(96a^2 - 65\left(a + \frac{h}{2}\right)^2 + 10\left(a + \frac{3h}{2}\right)^2 - \left(a + \frac{5h}{2}\right)^2 \right) = x_{-1}x_0, \\ \lambda_1(m_2) &= 2m_2(a) - \lambda_0(m_2) = 2a^2 - a(a-h) = x_0x_1, \\ \lambda_n(m_2) &= x_{n-1}x_n \quad \text{and} \quad \lambda_{n+1}(m_2) = x_nx_{n+1}.\end{aligned}$$

$\|\bar{Q}\|_\infty$ is equal to the Chebyshev norm of its quasi-Lagrange function $\bar{\Lambda} := \sum_{j \in J} |\bar{B}_j|$ and a direct study of the latter leads to $\|\bar{Q}\|_\infty = |\bar{\Lambda}|_\infty = \bar{\Lambda}(x_1) = \bar{\Lambda}(x_{n-1}) = 3/2$. ■

Proposition 2. *For all indices i , there holds $\bar{Q}f(x_i) - f(x_i) = O(h^4)$ and $\bar{Q}f(t_i) - f(t_i) = O(h^4)$, therefore $\bar{Q}f$ is superconvergent on both sets of points \mathcal{X}_n and \mathcal{T}_n .*

Proof: the superconvergence of $\bar{Q}f$ on \mathcal{X}_n and \mathcal{T}_n is verified by computing Taylor expansions on both sets of points with the help of a computer algebra system. Setting $\bar{E}f = \bar{Q}f - f$, we thus obtain successively

$$\begin{aligned}\bar{E}f(t_1) &= \bar{E}f(t_n) = 0, \\ \bar{E}f(t_i) &\sim \bar{C}_i h^4 D^4 f(t_i) \quad \text{where} \quad \bar{C}_2 = \bar{C}_{n-1} = \frac{7}{512}, \quad \bar{C}_i = \frac{1}{64}, \quad 3 \leq i \leq n-2, \\ \bar{E}f(x_i) &\sim \bar{C}'_i h^4 D^4 f(x_i) \quad \text{where} \quad \bar{C}'_1 = \bar{C}'_{n-1} = \frac{1}{64}, \quad \bar{C}'_i = \frac{3}{128}, \quad 2 \leq i \leq n-2. \blacksquare\end{aligned}$$

Remark 1. The quasi-interpolant \bar{Q} studied here is slightly different from the quadratic spline QI already studied in [9b]. The first and last coefficient functionals $\lambda_0(f)$ and $\lambda_{n+1}(f)$ have been modified in order to get the superconvergence at points $t_1, x_1, t_2, t_{n-1}, x_n, t_n$. The norm is also a little bit bigger.

Finally, we consider the *global approximation error* $\bar{Q}f - f$, which is known to be $O(h^3)$ for functions $f \in C^3(I)$. In each subinterval $I_i := [x_{i-1}, x_i]$, the local Lagrange interpolant $p_i \in \mathbb{P}_2$ on the set $T_i := \{x_{i-1}, t_i, x_i\}$ satisfies for all $x \in I_i$, $f(x) - p_i(x) = \frac{1}{6}(x - x_{i-1})(x - t_i)(x - x_i)D^3 f(\xi)$, with $\xi \in I_i$. Therefore, an elementary calculation leads to $\max_{x \in I_i} |f(x) - p_i(x)| \leq \frac{r}{216} h^3 \|D^3 f\|_\infty$. On the other hand, setting $\bar{p}_i = \bar{Q}f|_{I_i}$, and denoting λ_i for $\lambda_i(f)$, we obtain

$$\bar{p}_i(x_{i-1}) = \frac{\lambda_{i-1} + \lambda_i}{2}, \quad \bar{p}_i(t_i) = \frac{\lambda_{i-1} + 6\lambda_i + \lambda_{i+1}}{8}, \quad \bar{p}_i(x_i) = \frac{\lambda_i + \lambda_{i+1}}{2}.$$

Using Taylor expansions at x_i with integral remainders, we get for example $\bar{p}_i(x_i) = \frac{1}{16}(-f(t_{i-1}) + 9f(t_i) + 9f(t_{i+1}) - f(t_{i+2})) = f(x_i) + \int_{x_{i-1}}^{x_i} k_i(t) D^3 f(t) dt$, where the Peano kernel $k_i(t)$ is a piecewise quadratic function on the four intervals $[t_{i-1}, t_i]$, $[t_i, x_i]$, $[x_i, t_{i+1}]$, $[t_{i+1}, t_{i+2}]$. From that representation (and a

similar one at x_{i-1}), and setting $\bar{e}_i := f - \bar{p}_i$, we deduce the error bounds

$$|\bar{e}_i(x_{i-1})|, |\bar{e}_i(x_i)| \leq \frac{3h^3}{64} \|D^3 f\|_\infty, \quad |\bar{e}_i(t_i)| \leq \frac{h^3}{48} \|D^3 f\|_\infty.$$

The Lagrange basis $\{\ell_0, \ell_1, \ell_2\}$ of \mathbb{P}_2 based on T_i satisfying $\|\sum_{k=0}^2 |\ell_k|\|_\infty = \frac{5}{4}$, we then obtain

$$|(p_i - \bar{p}_i)(x)| = |\bar{e}_i(x_{i-1})\ell_0(x) + \bar{e}_i(t_i)\ell_1(x) + \bar{e}_i(x_i)\ell_2(x)| \leq \frac{15}{256} h^3 \|D^3 f\|_\infty.$$

Finally we deduce from the two above majorations

Proposition 3. *When $D^3 f$ is bounded, the following error estimate holds:*

$$\|f - \bar{Q}f\|_\infty \leq Ch^3 \|D^3 f\|_\infty, \quad \text{where } C < \frac{1}{18}.$$

2.2 Properties of the Gauss quasi-interpolant

The specific coefficient forms of the *Gauss quadratic spline quasi-interpolant* $\tilde{Q}f = \sum_{i \in J} \mu_i(f) B_i$, for extreme indices, are the following:

$$\begin{aligned} \mu_0(f) &:= \alpha_0 \hat{f}_0 + \beta_0 \tilde{f}_1 + \gamma_0 \hat{f}_1 + \delta_0 \tilde{f}_2, & \mu_{n+1}(f) &:= \alpha_0 \tilde{f}_{n+1} + \beta_0 \hat{f}_n + \gamma_0 \tilde{f}_n + \delta_0 \hat{f}_{n-1}, \\ \mu_1(f) &:= \alpha_1 \hat{f}_0 + \beta_1 \tilde{f}_1 + \gamma_1 \hat{f}_1 + \delta_1 \tilde{f}_2, & \mu_n(f) &:= \alpha_1 \tilde{f}_{n+1} + \beta_1 \hat{f}_n + \gamma_1 \tilde{f}_n + \delta_1 \hat{f}_{n-1}, \end{aligned}$$

where the parameters have the following values ($r = \sqrt{3}$):

$$\alpha_0 = (43 - r)/13, \quad \beta_0 = -(1 + r/2), \quad \gamma_0 = -(3 - r)/2, \quad \delta_0 = (5 + 2r)/26,$$

$$\alpha_1 = -(17 - r)/13, \quad \beta_1 = -\beta_0, \quad \gamma_1 = -\gamma_0, \quad \delta_1 = -\delta_0$$

Like \bar{Q} , the Gauss QI \tilde{Q} can be written in the quasi-Lagrange form

$$\tilde{Q}f = \sum_{j=1}^{n+1} \tilde{f}_j \tilde{B}_j + \sum_{j=0}^n \hat{f}_j \hat{B}_j, \quad \text{with } \begin{cases} \tilde{B}_j := \beta B_{j-1} + \alpha B_j \\ \hat{B}_j := \alpha B_j + \beta B_{j+1} \end{cases}, \quad 3 \leq j \leq n-2.$$

The coefficients in the basis $\{B_i, i \in J\}$ of the first and last five functions are given in the following table (with upper (resp. lower) indices for left (resp. right) functions).

i	0	1	2	3	
\hat{B}_0	α_0	α_1	0	0	\tilde{B}_{n+1}
\tilde{B}_1	β_0	β_1	0	0	\hat{B}_n
\hat{B}_1	γ_0	γ_1	β	0	\tilde{B}_n
\tilde{B}_2	δ_0	δ_1	α	0	\hat{B}_{n-1}
\hat{B}_2	0	0	α	β	\tilde{B}_{n-1}
	$n+1$	n	$n-1$	$n-2$	i

As for \bar{Q} , it is easy to verify that \tilde{Q} interpolates f at the points a and b , is exact on \mathbb{P}_2 , and has a small infinite norm.

Proposition 4. *The quasi-interpolant \tilde{Q} is exact on the space \mathbb{P}_2 of quadratic polynomials. Moreover its infinite norm satisfies $\|\tilde{Q}\|_\infty \approx 2.7$*

Proof: The infinite norm of the linear operator \tilde{Q} is equal to the Chebyshev norm of its Lebesgue function $\tilde{\Lambda} := \sum_{j=1}^{n+1} |\tilde{B}_j| + \sum_{j=0}^n |\hat{B}_j|$ and a direct study of the latter leads to $\|\tilde{Q}\|_\infty = |\tilde{\Lambda}|_\infty \approx 2.7$. ■

Proposition 5. *For all indices i , there holds $\tilde{Q}f(x_i) - f(x_i) = O(h^4)$ and $\tilde{Q}f(t_i) - f(t_i) = O(h^4)$, therefore $\tilde{Q}f$ is superconvergent on both sets of points \mathcal{X}_n and \mathcal{T}_n .*

Proof: As in Proposition 2, the superconvergence of $\tilde{Q}f$ on \mathcal{X}_n and \mathcal{T}_n is verified by computing Taylor expansions at those points with the help of a computer algebra system. Setting $\tilde{E}f := \tilde{Q}f - f$, we thus obtain successively

$$\begin{aligned} \tilde{E}f(t_i) &\sim \tilde{C}_i h^4 D^4 f(t_i), & \tilde{E}f(x_i) &\sim \tilde{C}'_i h^4 D^4 f(x_i), & \text{where} \\ \tilde{C}_1 = \tilde{C}_n &= \frac{61-9r}{6912}, & \tilde{C}_2 = \tilde{C}_{n-1} &= \frac{139-29r}{6912}, & \tilde{C}_i = \frac{73-16r}{1056}, & 3 \leq i \leq n-2, \\ \tilde{C}'_1 = \tilde{C}'_{n-1} &= \frac{43-5r}{1728}, & \tilde{C}'_i &= \frac{25-4r}{864}, & 2 \leq i \leq n-2. \end{aligned}$$

The values of constants lie between 6×10^{-3} and 4×10^{-2} . ■

We could also consider the global approximation error $\tilde{Q}f - f$, which is also $O(h^3)$ for functions f having a bounded third derivative. We do not give details here, the results being quite similar to those of Proposition 3.

3 Approximation of first derivatives

3.1 Superconvergence on the set \mathcal{G}_n

Proposition 6. *For $f \in C^4(I)$, the following error estimates hold at Gauss points \mathcal{G}_n for both quasi-interpolants $Q = \bar{Q}$ or \tilde{Q}*

$$DQf(u_i) - Df(u_i) = O(h^3), \quad DQf(v_i) - Df(v_i) = O(h^3), \quad 1 \leq i \leq n.$$

As the global approximation order of Df by DQf on the interval is only $O(h^2)$, there appears a superconvergence phenomenon of the first derivatives on \mathcal{G}_n , which does not hold on \mathcal{X}_n and \mathcal{T}_n .

Proof: As in Propositions 2 and 4 above, the results are verified by computing Taylor expansions on \mathcal{G}_n , \mathcal{X}_n and \mathcal{T}_n , with the help of a computer algebra system. We set $\bar{E}f := \bar{Q}f - f$ and $\tilde{E}f := \tilde{Q}f - f$, and we obtain successively

$$\begin{aligned} D\bar{E}f(u_i) &\sim \bar{C}_i h^3 D^4 f(u_i), & D\bar{E}f(v_i) &\sim \bar{C}'_i h^3 D^4 f(v_i), & \text{where} \\ \bar{C}_1 = \bar{C}_n &= \frac{(27-16r)}{1728}, & \bar{C}_2 = \bar{C}_{n-1} &= \frac{(27-23r)}{1728}, & \bar{C}_i &= -\frac{r}{108}, \quad 3 \leq i \leq n-2, \\ \bar{C}'_1 = \bar{C}'_n &= \frac{(27+16r)}{1728}, & \bar{C}'_2 = \bar{C}'_{n-1} &= \frac{(27+23r)}{1728}, & \bar{C}'_i &= -\frac{r}{108}, \quad 3 \leq i \leq n-2, \\ D\tilde{E}f(u_i) &\sim \tilde{C}_i h^3 D^4 f(u_i), & D\tilde{E}f(v_i) &\sim \tilde{C}'_i h^3 D^4 f(v_i), & \text{where} \\ \tilde{C}_1 = \tilde{C}_n &= \frac{(66-17r)}{2592}, & \tilde{C}_2 = \tilde{C}_{n-1} &= \frac{(6-25r)}{2592}, & \tilde{C}_i &= -\frac{r}{108}, \quad 3 \leq i \leq n-2, \\ \tilde{C}'_1 = \tilde{C}'_n &= \frac{(63+2r)}{2592}, & \tilde{C}'_2 = \tilde{C}'_{n-1} &= \frac{(15+16r)}{2592}, & \tilde{C}'_i &= -\frac{r}{108}, \quad 3 \leq i \leq n-2. \end{aligned}$$

(the values of these constants lie between $4 \cdot 10^{-4}$ and $4 \cdot 10^{-2}$). Direct computations also show that $D\bar{E}f(t_i)$, $D\bar{E}f(x_i)$, $D\tilde{E}f(t_i)$, $D\tilde{E}f(x_i)$ are only $O(h^2)$ ■

3.2 Improved global approximation of the first derivative

While DQf is a *continuous piecewise linear* function, a *better and smoother* global approximant of the first derivative Df is provided by the *Gauss quasi-interpolant* $\tilde{Q}(DQf)$ of DQf , which is a C^1 quadratic spline. Let us briefly study the global approximation order of Df by $\tilde{Q}(DQf)$. We first write

$$Df - \tilde{Q}(DQf) = (Df - \tilde{Q}Df) + \tilde{Q}(Df - DQf).$$

From the results of Section 2, the first error satisfies $Df - \tilde{Q}Df = O(h^3)$ when f has a fourth order bounded derivative. The second error can be written

$$\tilde{Q}(Df - DQf) = \sum_{j \in J} (\mu_j(Df) - \mu_j(DQf)) B_j.$$

The coefficient $\mu_j(Df) - \mu_j(DQf)$ being, for all $j \in J$, a linear combination of values of $Df - DQf$ on \mathcal{G}_n , we deduce from Proposition 6 that it is a $O(h^3)$. Therefore the same result holds for $\tilde{Q}(Df - DQf)$ because of the property $\sum_{j \in J} B_j = 1$. In fact, there are two close approximants: one is $\tilde{Q}(DQf)$ (i.e. the Gauss QI of the derivative of the uniform QI) and the other is $\tilde{Q}(D\tilde{Q}f)$ (i.e. the Gauss QI of the derivative of the Gauss QI of the given function f). Numerical experiments show that both approximants are quite close to each other and give a *global* approximation of Df in $O(h^3)$.

4 Derivation matrices

4.1 Direct derivation

Let $S = \sum_{j \in J} c_j B_j$ be a quadratic spline obtained as a quasi-interpolant Qf of a given function f . Denoting $\{N_j, -1 \leq j \leq n+1\}$ the *hat functions* with supports $[x_{j-1}, x_{j+1}]$, we have $S' = \sum_{j=0}^n \frac{1}{h} (c_{j+1} - c_j) N_j$, which implies that

$$\begin{aligned} S'(a) &= \frac{1}{h} (c_1 - c_0), \quad S'(b) = \frac{1}{h} (c_{n+1} - c_n), \quad \text{and for } 1 \leq i \leq n, \\ S'(u_i) &= \frac{1}{h} \left(-\frac{3+r}{6} c_{i-1} + \frac{r}{3} c_i + \frac{3-r}{6} c_{i+1} \right), \\ S'(v_i) &= \frac{1}{h} \left(-\frac{3-r}{6} c_{i-1} + \frac{r}{3} c_i + \frac{3+r}{6} c_{i+1} \right), \\ S'(t_i) &= \frac{1}{2} (S'(u_i) + S'(v_i)) = \frac{1}{2h} (c_{i+1} - c_{i-1}). \end{aligned}$$

When $S = \bar{Q}f$, let $\mathbf{f} \in \mathbb{R}^{n+2}$ be the vector with components $\{f_i, i \in J\}$ and let $\mathbf{f}' \in \mathbb{R}^{n+2}$ be the vector with components $\{f'_i = S'(t_i), i \in J\}$. These two vectors satisfy the equation $\mathbf{f}' = \bar{\mathcal{D}}\mathbf{f}$ where the derivation matrix $\bar{\mathcal{D}}$ on \mathcal{T}_n is a $(n+2) \times (n+2)$ 5-diagonal square matrix.

Similarly, when $S = \tilde{Q}f$, let $\mathbf{g} \in \mathbb{R}^{2n+2}$ be the vector with components $\{g_0 := \hat{f}_0; g_{2i-1} := \hat{f}_i, g_{2i} := \hat{f}_i, 1 \leq i \leq n; g_{2n+1} := \hat{f}_{n+1}\}$ and let $\mathbf{g}' \in \mathbb{R}^{2n+2}$ be the vectors with components $\{g'_0 := S'(a); g'_{2i-1} := S'(u_i), g'_{2i} := S'(v_i), 1 \leq i \leq n; g'_{2n+1} := S'(b)\}$. These two vectors satisfy the equation $\mathbf{g}' = \hat{\mathcal{D}}\mathbf{g}$ where the derivation matrix $\hat{\mathcal{D}}$ on \mathcal{G}_n is a $(2n+2) \times (2n+2)$ band matrix.

However, the approximation order given by direct derivation on \mathcal{T}_n is only $O(h^2)$. We will improve on this result in the next subsection.

Example: The following tables give the maximum error on derivatives on \mathcal{T}_n : $e'_k = \max_{i \in J} |f'(t_i) - f'_i|$, for $f := \phi_k$, $k = 1, 2$, computed for various partitions in n subintervals of $I = [0, 1]$, with $\phi_1(x) = (1 - x^2)^2/4$ and $\phi_2(x) = 0.9/(\cosh(10x - 2))^2 + 0.8/\cosh(100x - 60)$. We use the notation 1.1(-2) for 1.1×10^{-2} .

n	8	16	32	64
e'_1	1.1(-2)	2.8(-3)	7.2(-4)	1.8(-4)
n	256	512	1024	2048
e'_2	1.2	2.2(-1)	5.0(-2)	1.2(-2)

4.2 Improved derivation order on \mathcal{T}_n

The practical problem appearing in the construction of an efficient derivation matrix is that *the superconvergence of derivatives holds on \mathcal{G}_n* while in general data are given on \mathcal{T}_n . In this section, we shall improve the approximation error on derivatives up to $O(h^3)$ on \mathcal{T}_n by doing convenient linear combinations of values of $D\bar{Q}f(t_i)$. Using again the notations $S := \bar{Q}f$ and $f'_i := S'(t_i)$, $i \in J$, we consider the following approximations of f' on \mathcal{T}_n .

$$\begin{aligned}
 y'_0 &:= \frac{1}{6} (8f'_0 - 3f'_1 + f'_2), & y'_1 &:= \frac{1}{12} (-2f'_0 + 15f'_1 - f'_2) \\
 y'_j &:= \frac{1}{24} (-f'_{j-1} + 26f'_j - f'_{j+1}), & 2 \leq j \leq n-1 \\
 y'_n &:= \frac{1}{12} (-f'_{n-1} + 15f'_n - 2f'_{n+1}), & y'_{n+1} &:= \frac{1}{6} (f'_{n-1} - 3f'_n + 8f'_{n+1})
 \end{aligned}$$

Let us give a short proof of the fact that $f'(t_j) - y'_j$ is at least $O(h^3)$ for $4 \leq j \leq n-3$. Similar, but more complex calculations give the same results for the four first and last indices.

$$f'_{j-1} = S'(t_{j-1}) = \frac{1}{2h} (\lambda_j(f) - \lambda_{j-2}(f)) = \frac{1}{16h} (f_{j-3} - 10f_{j-2} + 10f_j - f_{j+1}).$$

$$f'_j = S'(t_j) = \frac{1}{2h} (\lambda_{j+1}(f) - \lambda_{j-1}(f)) = \frac{1}{16h} (f_{j-2} - 10f_{j-1} + 10f_{j+1} - f_{j+2}).$$

$$f'_{j+1} = S'(t_{j+1}) = \frac{1}{2h} (\lambda_{j+2}(f) - \lambda_j(f)) = \frac{1}{8h} (f_{j-1} - 10f_j + 10f_{j+2} - f_{j+3}).$$

which gives, for f smooth enough, by using Taylor expansions :

$$f'(t_j) - y'_j := f'(t_j) - \frac{1}{24} (-f'_{j-1} + 26f'_j - f'_{j+1}) = \frac{9h^4}{320} f^{(5)}(t_j) + O(h^6).$$

Let $\mathbf{y}' \in \mathbb{R}^{n+2}$ be the vector with components $\{y'_i, i \in J\}$. The vectors \mathbf{f} and \mathbf{y}' satisfy $\mathbf{y}' = \hat{\mathcal{D}}\mathbf{f}$. The improved derivation matrix $\hat{\mathcal{D}}$ has the following structure

$$\begin{bmatrix} a_1 & a_2 & a_3 & a_4 & a_5 & 0 & 0 & \dots & & \\ b_1 & b_2 & b_3 & b_4 & b_5 & 0 & 0 & 0 & \dots & \\ c_1 & c_2 & c_3 & c_4 & -\frac{3}{32} & \frac{1}{384} & 0 & 0 & \dots & \\ d_1 & d_2 & d_3 & d_4 & \frac{87}{128} & -\frac{3}{32} & \frac{1}{384} & 0 & \dots & \\ 0 & -\frac{1}{384} & \frac{3}{32} & -\frac{87}{128} & 0 & \frac{87}{128} & -\frac{3}{32} & \frac{1}{384} & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ \dots & 0 & -\frac{1}{384} & \frac{3}{32} & -\frac{87}{128} & 0 & \frac{87}{128} & -\frac{3}{32} & \frac{1}{384} & 0 \\ \dots & 0 & 0 & -\frac{1}{384} & \frac{3}{32} & -\frac{87}{128} & -d_4 & -d_3 & -d_2 & -d_1 \\ \dots & 0 & 0 & 0 & -\frac{1}{384} & \frac{3}{32} & -c_4 & -c_3 & -c_2 & -c_1 \\ \dots & 0 & 0 & 0 & 0 & -b_5 & -b_4 & -b_3 & -b_2 & -b_1 \\ \dots & 0 & 0 & 0 & 0 & -a_5 & -a_4 & -a_3 & -a_2 & -a_1 \end{bmatrix}$$

where the coefficients at the upper left and lower right corners are given by

$$\begin{aligned} a_1 &= -31/10, & a_2 &= 367/96, & a_3 &= -29/32, & a_4 &= 31/160, & a_5 &= -1/96, \\ b_1 &= -21/20, & b_2 &= 89/192, & b_3 &= 45/64, & b_4 &= -39/320, & b_5 &= 1/192. \\ c_1 &= 4/15, & c_2 &= -117/128, & c_3 &= 7/96, & c_4 &= 213/320, \\ d_1 &= -1/120, & d_2 &= 13/128, & d_3 &= -131/192, & d_4 &= 1/1920. \end{aligned}$$

In the examples below, we compare results obtained by using derivatives defined above with those obtained by approximating derivatives by classical finite differences. We use the following finite differences based on \mathcal{X}_n ($z_i = z(x_i)$):

$$\begin{aligned} z'_0 &\approx \frac{1}{h} \left(-\frac{11}{6}z_0 + 3z_1 - \frac{3}{2}z_2 + \frac{1}{3}z_3 \right), & z'_1 &\approx \frac{1}{h} \left(-\frac{1}{3}z_0 - \frac{1}{2}z_1 + z_2 - \frac{1}{6}z_3 \right), \\ z'_i &\approx \frac{1}{h} \left(\frac{1}{12}z_{i-2} - \frac{2}{3}z_{i-1} + \frac{2}{3}z_{i+1} - \frac{1}{12}z_{i+2} \right), & 2 \leq i &\leq n-2, \\ z'_{n-1} &\approx \frac{1}{h} \left(\frac{1}{3}z_n + \frac{1}{2}z_{n-1} - z_{n-2} + \frac{1}{6}z_{n-3} \right), & z'_n &\approx \frac{1}{h} \left(\frac{11}{6}z_n - 3z_{n-1} + \frac{3}{2}z_{n-2} - \frac{1}{3}z_{n-3} \right). \end{aligned}$$

The errors at the endpoints are in $O(h^3)$ while those at central points are in $O(h^4)$.

Example 2 : The first line (QI) give the maximum errors on the approximate derivatives on \mathcal{T}_n : $e'_k = \max_{i \in J} |f'(t_i) - y'_i|$, for various values of n , and for $f := \phi_k$, $k = 1, 2, 3$, on $I = [-1, 1]$, with $\phi_1(x) = \frac{1}{4}(1 - x^2)^2$, $\phi_2(x) := \frac{1}{1+16x^2}$, $\phi_3(x) := \sin(\pi x) + \sin(5\pi x)$. The second line (FD) gives the estimation of first derivatives given by classical finite differences on \mathcal{X}_n . Both errors are in $O(h^3)$. The notation $6.5(-3)$ stands for 6.5×10^{-3} .

n	8	16	32	64	128
$e'_1(\text{QI})$	6.5(-3)	8.1(-4)	1.0(-4)	1.3(-5)	1.6(-6)
$e'_1(\text{FD})$	2.3(-2)	2.9(-3)	3.7(-4)	4.6(-5)	5.7(-6)
$e'_2(\text{QI})$	1.3	0.32	2.8(-2)	2.5(-3)	1.7(-4)
$e'_2(\text{FD})$	0.12	0.22	4.0(-2)	3.0(-3)	2.0(-4)
$e'_3(\text{QI})$	19.4	6.7	0.71	4.9(-2)	3.1(-3)
$e'_3(\text{FD})$	30.8	13.9	3.1	0.25	1.7(-2)

4.3 Improved global approximation of the first derivative

As in section 3.2, a better approximation of the first derivative on \mathcal{T}_n provides a *better and smoother* global approximation of this function on the interval I . It suffices to take the quasi-interpolant \bar{Q} on the modified values of derivatives $\{y'_j, j \in J\}$ given in the previous section. Let us denote by \bar{g}' this QI: $\bar{g}' = \sum_{j \in J} y'_j \bar{B}_j$. As the approximation order of \bar{Q} is $O(h^3)$ and $y'_j - f'(t_j) = O(h^3)$, we deduce immediately that, for f smooth enough ($D^4 f$ bounded), $\|f' - \bar{g}'\|_\infty = O(h^3)$.

Example: The following table give the uniform errors: $e'_k = \max_{x \in I} |f'(x) - \bar{g}'(x)|$, for $f := \phi_k$, $k = 1, 2, 3$, with the same functions as in previous example, obtained with various partitions in n subintervals of $I = [-1, 1]$. The computed errors are at least $O(h^3)$.

n	8	16	32	64	128
e'_1	6.5(-3)	8.1(-4)	1.0(-4)	1.3(-5)	1.6(-6)
e'_2	1.4	0.44	6.4(-2)	4.9(-3)	3.9(-4)
e'_3	20	7.0	0.71	5.9(-2)	4.0(-3)

5 Collocation methods for univariate problems

Let us consider the univariate Dirichlet problem on $I = [a, b]$ with a differential operator of Sturm-Liouville type :

$$-D(p(x)Du(x)) + r(x)u(x) = f(x), \quad u(a) = u(b) = 0,$$

p being a C^1 function, r a continuous function and f a piecewise continuous function on I . Let $\mathbf{u} \in \mathbb{R}^n$ be the vector of unknown values of u on $\mathcal{T}_n^* := \mathcal{T}_n \setminus \{a, b\}$, and let $\tilde{\mathbf{u}} \in \mathbb{R}^{n+2}$ be the augmented vector with 0 as first and last components. Applying the derivation matrix $\hat{\mathcal{D}}$ gives an approximation $\hat{\mathcal{D}}\tilde{\mathbf{u}} \in \mathbb{R}^{n+2}$ of first derivatives of u on \mathcal{T}_n . Then, we multiply this vector by the diagonal matrix $P \in \mathbb{R}^{n+2}$ defined by $P(i, i) = p(t_i)$ and we multiply again by the derivation matrix. Denoting by $R \in \mathbb{R}^{n+2}$ the diagonal matrix defined by $R(i, i) = r(t_i)$, we see that the left-hand side of the differential equation is approximated by the vector

$$\hat{A}\tilde{\mathbf{u}} := -\hat{\mathcal{D}}P\hat{\mathcal{D}}\tilde{\mathbf{u}} + R\tilde{\mathbf{u}}$$

Let $A \in \mathbb{R}^n$ be the matrix of order n deduced from \hat{A} by deleting the first and last lines and columns, it is well known ([11], chapter 7) that the problem is equivalent to solving the linear system $A\mathbf{u} = \mathbf{f}$ where $\mathbf{f} \in \mathbb{R}^n$ is the vector of values of f on \mathcal{T}_n^* . Numerical experiments show that the approximation order of the solution is $O(h^3)$.

Example 4. Dirichlet problems $-u'' = f$ with $u(-1) = u(1) = 0$ and successive right hand sides $f = \phi_k$, $k = 1, 2, 3$, with $\phi_1(x) = -2 + 12x^2$, $\phi_2(x) = \pi^2(\sin(\pi x) + 25 \sin(5\pi x))$, $\phi_3(x) = 16 \exp(4x)$, and corresponding solutions $u = v_k$: $v_1(x) = x^2(1 - x^2)$, $v_2(x) = \sin(\pi x) + \sin(5\pi x)$, $v_3(x) = \sinh(4)x + \cosh(4) - \exp(4x)$. The first line (QI) give the maximum errors $e_k := \max_{i \in J} |u(t_i) - \mathbf{u}_i|$, $k = 1, 2, 3$, for various values of n . The second line (FD) gives the errors obtained by using the derivation matrix associated with

classical finite differences on \mathcal{X}_n . Both errors are in $O(h^3)$.

n	8	16	32	64	128
$e_1(\text{QI})$	4.7(-3)	3.1(-4)	2.0(-5)	1.3(-6)	8.1(-8)
$e_1(\text{FD})$	5.0E-3	3.1(-4)	2.0(-5)	1.2(-6)	7.7(-8)
$e_2(\text{QI})$	17	1.9	7.5(-2)	3.8(-3)	2.3(-4)
$e_2(\text{FD})$	11.4	1.9	1.3(-1)	7.4(-3)	3.7(-4)
$e_3(\text{QI})$	0.84	0.10	8.7(-3)	6.4(-4)	4.3(-5)
$e_3(\text{FD})$	1.11	0.11	9.0(-3)	7.7(-4)	5.6(-5)

Example 5. Dirichlet problems $-u'' + u = f$ with $u(-1) = u(1) = 0$ and successive right-hand sides $f = \phi_k$, $k = 1, 2$, with $\phi_1(x) = (1 + \pi^2) \sin(\pi x)$, $\phi_2(x) = \exp(x/2)((100\pi^2 + \frac{3}{4}) \sin(10\pi x) - 10\pi \cos(10\pi x)) + (9\pi^2 + 1) \sin(3\pi x)$, and corresponding solutions $u = v_k$: $v_1(x) = \sin(\pi x)$, $v_2(x) = \exp(x/2) \sin(10\pi x) + \sin(3\pi x)$. The first line (QI) give the maximum errors $e_k := \max_{i \in J} |u(t_i) - \mathbf{u}_i|$, $k = 1, 2, \dots$, for various values of n . The second line (FD) gives the errors obtained by using the derivation matrix associated with classical finite differences on \mathcal{X}_n . Both errors are in $O(h^3)$.

n	8	16	32	64	128
$e_1(\text{QI})$	1.8(-2)	1.2(-3)	7.6(-5)	4.8(-6)	3.0(-7)
$e_1(\text{FD})$	2.3(-2)	1.2(-3)	8.2(-5)	5.3(-6)	3.4(-7)
$e_2(\text{QI})$	39	22	2.9	0.12	6.3(-3)
$e_2(\text{FD})$	41	22	3.4	0.24	1.3(-2)

On these five examples, the solutions obtained by QI are quite comparable with those obtained by FD, and often slightly better. Both they need the solution of a system of linear equations.

6 Bivariate spline quasi-interpolants on a rectangle

We briefly sketch the methods developed for bivariate extensions of the previous QIs to functions defined on a domain $\Omega := [a, b] \times [c, d]$, with uniform partitions $\mathcal{X}_n = \{x_j = a + jh, 0 \leq j \leq m\}$, $\mathcal{Y}_n = \{y_k = c + kh, 0 \leq k \leq n\}$, and midpoints $s_j = \frac{1}{2}(x_{j-1} + x_j)$ and $t_k = \frac{1}{2}(y_{k-1} + y_k)$. We put $J = \{0, \dots, m+1\}$ and $K = \{0, \dots, n+1\}$ and define $s_0 = a$, $s_{m+1} = b$, $t_0 = c$, $t_{n+1} = d$. We consider *tensor products* and *discrete blending sums* [4] of univariate QIs : in

that case, we get biquadratic QIs. We show that they are superconvergent at all points (ξ_j, η_k) where $\xi_j = x_j$ or s_j and $\eta_k = y_k$ or t_k . Finally, we construct derivation matrices with an application to the solution of the classical bivariate Dirichlet problem $-\Delta u = f$ by associated collocation methods. In this section, \mathbb{P}_n denotes the space of polynomials of total degree at most n and $\mathbb{P}_{p,q}$ the space of polynomials of partial degrees at most p in x and q in y . Monomials are denoted $m_{p,q}(x, y) := x^p y^q = m_p(x)m_q(y)$.

6.1 Tensor product and discrete blending sum of univariate QIs

The tensor product $T = P_2Q_2$ of the two univariate quadratic spline QIs :

$$P_2f(x) := \sum_{j \in J} f(s_j) \bar{B}_j(x), \quad Q_2g(y) := \sum_{k \in K} g(t_k) \bar{B}_k(y),$$

is the bivariate QI defined by

$$TF(x, y) := \sum_{(j,k) \in J \times K} F(s_j, t_k) \bar{B}_{j,k}(x, y), \quad \text{with } \bar{B}_{j,k}(x, y) := \bar{B}_j(x) \bar{B}_k(y).$$

Proposition 7. *The quasi-interpolant T is exact on the space $\mathbb{P}_{2,2}$ of bi-quadratic polynomials. Moreover $\|T\|_\infty = 9/4$.*

Proof. The proof is classical and based on similar techniques to those used e.g. in [2] or [4].

The discrete blending sum (see [2, 4]) of the four quadratic spline QIs :

$$\begin{aligned} P_1f(x) &:= \sum_{j \in J} f(s_j) B_j(x), & P_2f(x) &:= \sum_{j \in J} f(s_j) \bar{B}_j(x), \\ Q_1g(y) &:= \sum_{k \in K} g(t_k) B_k(y), & Q_2g(y) &:= \sum_{k \in K} g(t_k) \bar{B}_k(y), \end{aligned}$$

is the bivariate QI defined by

$$RF(x, y) := (P_1Q_2 + P_2Q_1 - P_1Q_1)F(x, y) = \sum_{(j,k) \in J \times K} F(s_j, t_k) \tilde{B}_{j,k}(x, y)$$

where the basic functions $\tilde{B}_{j,k}$ are given by

$$\tilde{B}_{j,k}(x, y) := B_j(x) \bar{B}_k(y) + \bar{B}_j(x) B_k(y) - B_j(x) B_k(y).$$

As P_1 and Q_1 are exact on \mathbb{P}_1 , and P_2 and Q_2 are exact on \mathbb{P}_2 , it is easy to verify that R is exact on $\mathbb{P}_{1,2} \oplus \mathbb{P}_{2,1}$ which contains \mathbb{P}_2 . Indeed, for all pairs (p, q) with $0 \leq p, q \leq 2$ and $(p, q) \neq (2, 2)$, we have:

$$Rm_{p,q} = (P_1m_p)m_q + m_p(Q_1m_q) - (P_1m_p)(Q_1m_q) = m_{p,q}.$$

For $p \leq 1$, $P_1m_p = m_p$, therefore $Rm_{p,q} = m_p m_q + m_p(Q_1m_q) - m_p(Q_1m_q) = m_{p,q}$. The proof is similar for $q \leq 1$. In addition, from $\|P_2\|_\infty = \|Q_2\|_\infty = \frac{3}{2}$ and $\|P_1\|_\infty = \|Q_1\|_\infty = 1$, we deduce that $\|R\|_\infty \leq 4$. So, we have proved the following:

Proposition 8. *The quasi-interpolant R is exact on the space of polynomials $\mathbb{P}_{1,2} \oplus \mathbb{P}_{2,1}$. Moreover $\|R\|_\infty \leq 4$.*

6.2 Superconvergence properties

Superconvergence means exact interpolation for monomials of partial degree at most 3, i.e. $(P_2m_p - m_p)(\xi_j) = 0$ and $(Q_2m_q - m_q)(\eta_k) = 0$ for $0 \leq p, q \leq 3$, $\xi_j = x_j$ or s_j , $\eta_k = y_k$ or t_k . Therefore

$$(Tm_{p,q} - m_{p,q})(\xi_j, \eta_k) = P_2m_p(\xi_j)Q_2m_q(\eta_k) - m_p(\xi_j)m_q(\eta_k) = 0,$$

i.e. T is superconvergent at all gridpoints (ξ_j, η_k) . For the operator R , we get

$$\begin{aligned} (Rm_{p,q} - m_{p,q})(\xi_j, \eta_k) &= P_1m_p(\xi_j)m_q(\eta_k) + m_p(\xi_j)Q_1m_q(\eta_k) \\ &\quad - P_1m_p(\xi_j)Q_1m_q(\eta_k) - m_p(\xi_j)m_q(\eta_k) \\ &= (P_1m_p(\xi_j) - m_p(\xi_j))(m_q(\eta_k) - Q_1m_q(\eta_k)) = O(h^4), \end{aligned}$$

since $P_1f - f = O(h^2)$ and $Q_1g - g = O(h^2)$ for smooth functions f and g . Thus, there is no exact interpolation, but the approximation order is four. By Taylor's formula, this also implies that $(RF - F)(\xi_j, \eta_k) = O(h^4)$ for all smooth bivariate functions F . The superconvergence of derivatives will be studied elsewhere.

7 Bivariate Dirichlet problem

In order to illustrate the possibilities of the bivariate collocation method deduced from tensor product quasi-interpolation, we consider the classical model

problem $-\Delta u = f$ on a square domain Ω with Dirichlet boundary conditions. As discrete approximation of the Laplacian, we use the Kronecker product of matrices (see [11], chapter 7) $K = A \otimes I + I \otimes A$, where A is the matrix deduced from the derivation matrix \hat{D} (Sections 4.2 and 5). In that case, denoting by \mathbf{u} the vector of components of the solution in the basis of tensor-product B-splines and by \mathbf{f} the vector of values of f at the interior points of Ω , the linear system to solve is then $-K\mathbf{u} = \mathbf{f}$.

Examples. Let the right-hand sides be $f_1 = 4(1 - 3x^2)(1 - y^2)^2 + 4(1 - 3y^2)(1 - x^2)^2$ on $\Omega = [-1, 1]^2$ and $f_2 = 64[((2x - 1)y(y - 1))^2 + ((2y - 1)x(x - 1))^2] \sin(4x(x - 1)y(y - 1)) - 32[x(x - 1) + y(y - 1)] \cos(4x(x - 1)y(y - 1))$ on $\Omega = [0, 1]^2$. The corresponding exact solutions are respectively $u_1 = ((1 - x^2)(1 - y^2))^2$ and $u_2 = 4 \sin(4x(x - 1)y(y - 1))$. The first line (QI) give the maximum errors e_1 and e_2 at the points of $\mathcal{T}_n \times \mathcal{T}_n$ for various values of n (we give between brackets the numerical convergence order). The second line (FD) gives the errors obtained by using the derivation matrix associated with classical finite differences on \mathcal{X}_n .

n	8	16	24	32	40	48
$e_1(\text{QI})$	3.9(-3)	2.8(-4) [3.8]	5.8(-5) [3.9]	1.9(-5) [3.9]	7.9(-6) [3.9]	3.8(-6) [3.9]
$e_1(\text{FD})$	7.6(-3)	4.2(-4) [4.2]	7.8(-5) [4.1]	2.4(-5) [4.1]	9.7(-6) [4.1]	4.6(-6) [4.1]
$e_2(\text{QI})$	2.3(-4)	2.4(-5) [3.3]	5.4(-6) [3.6]	1.9(-6) [3.6]	8.4(-7) [3.7]	4.2(-7) [3.8]
$e_2(\text{FD})$	2.5(-4)	4.9(-5) [2.3]	1.2(-5) [3.4]	4.3(-6) [3.7]	1.8(-6) [3.7]	9.3(-7) [3.8]

Remark. We get convergence orders which seem closer to 4 than to 3. This is due to the fact that derivatives are approximated to the 4th order at most points inside the domain (see Section 4).
