Off-label use of medicines in children: can available evidence avoid useless paediatric trials?

The case of proton pump inhibitors for the treatment of gastroesophageal reflux disease

Abstract

Purpose In some cases of drug therapy, the available evidence might be sufficient to extend the indications to children without further clinical studies.

Methods We reviewed the available evidence for one of the categories of drugs most frequently used off-label in children: proton pump inhibitors (PPIs) used for the treatment of gastroesophageal reflux disease (GERD). A classification of the appropriateness of off-label use of PPIs in children with GERD was also performed.

Results Of the five PPIs evaluated, only omeprazole has a paediatric indication in Europe. Overall, 19 clinical trials were retrieved and evaluated on the basis of pharmacokinetics, efficacy and safety data. The off-label use of omeprazole, esomeprazole and lansoprazole in children was evaluated as appropriate given the consistent available evidence retrieved in literature.

Conclusion This study demonstrates the existence of a large body of clinical evidence on the use of PPIs in children. Regulatory agencies and ethical committees should cope with this issue for ethical reasons to avoid unnecessary trial replication.

Introduction

The use of unlicensed and off-label medicines in children is widespread and has raised an increasing concern over the last years. In the European Union (EU), 50% or more of the medicines used in children have only been studied in adults, and not necessarily for the same indication [1]. The general lack of information and appropriate pharmaceutical formulations for use in children may expose them to unwanted adverse events or underdosing without the expected efficacy. The need for more studies to obtain paediatric information for medicines used in children is now a matter of consensus on a global basis [2, 3]. The awareness of off-label drug usage in the daily practice by paediatricians and the need to identify specific off-label clinical priorities in paediatrics have been documented in an observational study conducted in 32 Italian Departments of Paediatrics [4].

The policy implemented in the USA, culminating in the Pediatric Research Equity Act of 2003, paved the way for the new European legislation (the 'Paediatric Regulation'), which was adopted in January 2007 with the objective to guide the development and authorisation of medicines for

use in children aged 0–17 years [5–7]. This legislation was designed to better protect the health of children in the EU. A Paediatric Committee was established within the European Medicines Agency (EMA) with the intent to provide scientific opinions on any development plan for paediatric medicines. The Committee has identified therapeutic areas where clinical studies on medicinal products for children are considered both a priority and a prerequisite for granting a paediatric indication [8].

A recent draft guidance has been issued by the U.S. Food and Drug Administration (FDA) with the aim to effectively manage the off-label phenomenon, enabling sponsors to distribute publications about off-label use of approved drugs to prescribers [9]. The potential pros and cons of this approach have been strongly debated among the scientific and regulatory community at the international level [10].

The current scenario on paediatric research and regulation raises a new challenging question: is it always necessary to perform additional clinical studies in children? Our hypothesis is that, in some instances, the evidence already available may be sufficient to extend the indications to children without further clinical studies. This would allow the translation of the existing evidence into clinical practice, minimising regulatory hurdles and avoiding the unethical replication of trials.

To test this hypothesis we reviewed the available evidence for one of the categories of drugs most frequently used off-label in children: proton pump inhibitors (PPIs) for the treatment of gastroesophageal reflux disease (GERD). The rationale for choosing PPIs stems from the following considerations. The role of PPIs for the treatment of GERD is identified as a paediatric need by the EMA Paediatric Committee [8]. However, although PPIs do not have an indication for GERD in infants, clinical guidelines from the North American Society for Pediatric Gastroenterology and Nutrition address the use of PPIs for this age group [11]. Which line of action should be followed to better protect paediatric patients? This question is of particular importance given the enormous increase in the use of PPIs in infants for presumed GERD that has been documented (in the 6 years from 1999 through 2004, there was a more than sevenfold increase) and the largely inappropriate prescription of PPIs in children presenting physiological GERD that has been recently reported [12, 13].

The aim of the study was to review the clinical evidence available in the published scientific literature concerning the use of PPIs for the treatment of GERD in the paediatric population in order to establish whether the absence of authorised indications can be justified. An additional aim of the study is to describe possible differences in the PPI-approved indications for the treatment of GERD in the paediatric population in the two largest regulatory agencies, EMA and FDA.

Methods

We performed a preliminary search to determine the regulatory status of approved PPIs (omeprazole, esomeprazole, lansoprazole, rabeprazole and pantoprazole) in Europe and the USA. The European summaries of product characteristics (SPCs) were retrieved from the EUDRANET database (<http://ec.europa.eu/idabc/en/document/2291>); the U.S. patient information leaflets were retrieved from the FDA website (www.fda.gov). The update of these documents was surveyed until June 2008. Information on paediatric indications was abstracted from such documents, and a comparison between Europe and the USA was then carried out.

A comprehensive search on the MEDLINE and EMBASE databases (January 1990–June 2008) was performed. All clinical trials on the off-label use of PPIs for the treatment of GERD in children (age 0–17 years) were considered eligible for inclusion. For the purpose of this analysis, the following parameters were assessed: study design, trial information (country, centres), objectives (endpoints), patients population, study duration, posology, formulation and main findings (as reported by the authors). Given the objective of the study, the analysis was restricted to the trials conducted on patients' age ranges not already included in approved EU indications (e.g. for omeprazole, only studies including children aged 0–2 years were analysed).

We defined a priori a common data acquisition form to be completed using the information collected from the selected articles [14–32]. The information was used to assess the available evidence on the pharmacokinetics (PK), efficacy and safety of each drug. The safety profile of each drug was evaluated through a comparison of adverse events (AEs) for adults listed in SPC versus the AEs reported in paediatric trials. A specific search on the MEDLINE and EMBASE databases was performed in order to retrieve safety data collected through reviews and observational studies.

On the basis of the retrieved evidence, a classification of the appropriateness of off-label use of PPIs in children with GERD was performed. Each drug was ranked as having a high, moderate or scarce appropriateness when administered in children, depending on the fulfilment of three pre-specified criteria. Specifically, a high appropriateness was attributed to a compound when at least two efficacy trials and two PK studies were retrieved and a comparable safety profile versus adults was assessed. Lack of compliance with one or more of the above-mentioned criteria leads to a decrease in the ranking of appropriateness. For the classification of appropriateness, strength of the endpoints and robustness of the study designs have been also considered as two additional criteria. The use of 24-h pH

monitoring and/or endoscopy, although surrogate end-points, are considered to be acceptable predictors of efficacy [33]. Double-blind randomised controlled trials were considered the highest level of evidence for testing medicines.

Results

The five PPIs currently marketed in the EU—omeprazole, esomeprazole, lansoprazole, rabeprazole and pantoprazole—were approved through a mutual recognition procedure. Of these five PPIs, only omeprazole has a paediatric indication (i.e. children aged ≥ 2 years). Esomeprazole, which is the *S*-isomer of omeprazole, does not formally have any paediatric indication, although the approved European SPC contains information on posology in children under the age of 12 years. At the end of June 2007 further information on the posology in adolescents in terms of the treatment of GERD was added for the pantoprazole SPC. However, no changes were included in the therapeutic indication section of the SPC.

The scenario in the USA appears to be different: three out of five compounds (omeprazole, esomeprazole, lansoprazole) are currently authorised for children, although with the exclusion of infant and neonate age groups (Table 1). It is noteworthy that lansoprazole and esomeprazole are approved for children aged 1–17 in the USA but not in the EU. The most recently marketed PPIs (rabeprazole and pantoprazole) are not indicated for use in children in the USA nor in the EU.

Nineteen clinical trials testing PPIs in the treatment of GERD in children were retrieved; these are summarised in Table 2. Of these, eight were multicentre trials. More than 40% of the trials evaluated were conducted in the USA.

Table 1 Approved indications of PPIs for the treatment of GERD in the European Union and the USA

Drug	EU indication	US indication
Omeprazole	GERD ≥ 2 years	GERD 2–16 years
Esomeprazole	Not authorised in children ^a	GERD 1–17 years
Lansoprazole	Not authorised in children	GERD 1–17 years
Pantoprazole	Not authorised in children ^a	Not authorised in children
Rabeprazole	Not authorised in children	Not authorised in children

PPI, Proton pump inhibitors; GERD, gastroesophageal reflux disease
^aInformation on posology in adolescents (≥ 12 years) with GERD is available in the summaries of product characteristics (SPC)

Findings on omeprazole consisted of six efficacy trials, two also focussing on the PK profile. The study duration ranged from 7 days to 3 months, and a total of 151 children were enrolled; three studies were randomised controlled trials (RCTs).

The evidence for lansoprazole consisted of six studies (one was a RCT), testing efficacy and PK, with a study duration ranging from 5 days to 3 months. Overall, 282 patients were enrolled. Four RCTs on esomeprazole were retrieved: these were aimed at defining the PK, efficacy and safety profile, with a total of 257 enrolled children. The improvement of GERD symptoms was investigated in two efficacy trials (one was a RCT) with pantoprazole. The population enrolled consisted of 68 children with a mean study duration of 1.5 month. Finally, for the latest marketed PPI, rabeprazole, only one trial investigating PK and safety was retrieved, with a population involving 24 children.

All PK studies were designed with the aim of determining doses. The posology adopted was homogeneous across trials testing the same compound, and it was reported on a milligram/kilogram per day basis, which is appropriate in children. On the other hand, heterogeneity in terms of formulations was observed across all of the evaluated trials. It should also be highlighted that none of these studies was designed as a comparative trial testing different PPIs. For omeprazole and esomeprazole, evidence on efficacy and PK emerged from at least three RCTs (in many cases, the trials had a double-blind design).

Of note, in more than 70% of the efficacy trials, the activity of each drug was evaluated on end points based on the 24-h pH monitoring, often accompanied by an endoscopy.

On the basis of the AEs reported in the trials included in the analysis, all compounds presented a safety profile in children that was comparable with one described in adults. Only in the case of omeprazole were AEs of the respiratory system reported more frequently in children aged 0–2 years than in adults. This is also confirmed by recent literature data [34]. Two reviews confirmed our findings in terms of the comparability of the omeprazole, lansoprazole, esomeprazole and pantoprazole safety profiles between children and adults [33, 35]. A retrospective observational study that evaluated the long-term safety and efficacy of omeprazole and lansoprazole and involved 166 children reported that PPIs are efficacious and well tolerated for continuous use for as long as 11 years in children [36].

The off-label use of omeprazole, lansoprazole and esomeprazole in children was evaluated as highly appropriate given the consistent available evidence on PK, efficacy and safety (Table 3). Moderate appropriateness was attributed to pantoprazole, due to the lack of PK data and insufficient efficacy trials. Since no adequate evidence

Table 2 Clinical trials testing PPIs in children with GERD [14–32]

Drug	Study design	Trial information (country, centre)	Objective (End-point)	Patients population (<i>n</i> , age)	Posology	Study duration	Formulation	Main findings (as reported by authors)
Omeprazole	RCT	Italy, single-centre	Efficacy (24 h pH monitoring, endoscopy, histological evaluation, and GERD symptom assessment chart)	<i>n</i> = 32; 6 months to 13.4 years	40 mg/dies per 1.73 m ²	8 weeks	Capsule content or capsule	Efficacious reduction of intragastric acidity and intra-oesophageal acid exposure. Healing of oesophagitis and relief of symptoms.
	RCT, double-blind, placebo controlled, crossover	Australia, single-centre	Efficacy (24 h pH monitoring, and GERD symptom assessment chart)	<i>n</i> = 10; 50±9 days	0.7 mg/kg/dies	7 days	Liquid	Significantly effective in normalizing pathological acid GERD. Not significantly effective in reducing symptom frequency.
	RCT, double blind, placebo controlled, crossover	Australia, multicentre	Efficacy (24 h pH monitoring and Cry/fuss diary and visual analogue scale of irritability)	<i>n</i> = 30; 3–12 months	5–10 kg: 10 mg/dies; >10 kg: 10 mg/bid	2 weeks	Microspheres in apple juice	Despite effective acid suppression, omeprazole failed to suppress symptoms of irritability
	CT, open-label	Multinational, multicentre	PK and efficacy (main PK parameters, 24 h pH monitoring, endoscopy, and standardized questionnaire)	<i>n</i> = 57; 1–16 years	0.7–3.5 mg/kg/dies	12 weeks	Capsule in children; microgranules in infants	Highly effective for treatment of erosive oesophagitis and symptoms of GERD. Doses required are much greater than those required for adults.
	CT, open-label	Belgium, single-centre	Efficacy (24 h pH monitoring, endoscopy, and Cry/fuss reports)	<i>n</i> = 12; 2.9±0.9 months	0.5 mg/kg/die	6 weeks	Capsule content in milk or water	Marked decrease in symptoms, endoscopic and histological signs of oesophagitis, and intragastric acidity.
	CT, open-label	UK, single-centre	PK and Efficacy (main PK parameters, 24 h pH monitoring); 1.25–20 months	<i>n</i> = 10;	0.7 mg/kg/die	2 weeks	Microgranules in alkaline vehicle	Effective treatment for GERD in children younger than 2 years. The majority respond to a dosage of 0.7 mg/kg/dies
Lansoprazole	CT, open-label	USA, multicentre	Efficacy (endoscopy, investigator interview, and patients daily diary)	<i>n</i> = 87; 12–17 years	15 or 30 mg/dies	8 weeks	Capsule	15 or 30 mg reduced symptoms of GER

CT, open-label	France, single-centre	PK and efficacy (main PK parameters, 24 h pH monitoring, endoscopy)	<i>n</i> = 23; 3 months–13.4 years	0.8–1.4 mg/kg/dies	7 days	Capsule in children; microgranules in infants	The optimal effective starting dosage is 14 mg/kg/dies. PK is similar to adults.
CT, open-label	Italy, single-centre	Efficacy (24 h pH monitoring, endoscopy)	<i>n</i> = 35; 3–15 years	Group A: 1.3–1.5 mg/kg/dies; Group B: 0.8–1.0 mg/kg/dies	12 weeks	Capsule or microgranules in acid vehicle	Effective in healing esophagitis and improving GERD symptoms. An initial dose of 1.5 mg/kg/die is suggested.
CT, open-label	USA, multicentre	PK/PD (main PK parameters, 24 h pH monitoring, investigator interview)	<i>n</i> = 8; 13–24 months	15 mg dies to bid	8–12 weeks	N.A.	PK and PD properties were similar to those observed in older children and adults.
CT, open-label	USA, multicentre	PK and efficacy (main PK parameters, 24 h pH monitoring, GERD symptoms assessment)	<i>n</i> = 66; 1–12 years	15 mg/dies if ≤ 30 kg; 30 mg/dies if > 30 kg (mean dose 0.9 mg/kg/dies)	8–12 weeks	N.A.	Effective symptom relief dose is 1.2 mg/kg/die. PK properties were similar to those previously observed in adults
RCT, double-blind	USA, multicentre	PK and efficacy (main PK parameters, 24 h pH monitoring and GERD symptoms assessment)	<i>n</i> = 63; 12–17 years	15 vs 30 mg/dies	5 days	Tablet	PK properties were similar to those previously observed in adults. 15 or 30 mg effectively relieves symptoms of GERD
Esomeprazole RCT, open-label	USA, single-centre	PK (main PK parameters)	<i>n</i> = 31; 1–11 years	1–5 years: 5 vs 10 mg/dies; 6–11 years: 10 vs. 20 mg/dies	5 days	Capsule	PK properties may be both dose- and age-dependent. Younger children (1–5 years) might have more rapid metabolism.
RCT, open-label	USA, single-centre	PK (main PK parameters)	<i>n</i> = 28; 12–17 years	20 vs. 40 mg/die	8 days	Capsule	Well tolerated at all doses. PK properties were dose- and time-dependent. Well tolerated at both doses.
RCT, single-blind	Australia, single-centre	PK and efficacy (main PK parameters, 24 h pH monitoring, infant GERD questionnaire)	<i>n</i> = 50; 1–24 months	0.25 vs. 1 mg/kg/dies	1 week	Capsule content in applesauce	0.25 and 1 mg/kg/dies provided dose-related acid suppression and decreased esophageal acid exposure.
RCT, double blind	Multinational, multicentre	Efficacy and safety (GERD symptoms assessment with diary, physical examinations, clinical laboratory evaluations, evaluation of adverse events)	<i>n</i> = 148; 12–17 years	20 vs. 40 mg/dies	8 weeks	Capsule	20 or 40 mg were well tolerated and GERD-related symptoms were significantly reduced

Table 2 (continued)

Drug	Study design	Trial information (country, centre)	Objective (End-point)	Patients population (n, age)	Posology	Study duration	Formulation	Main findings (as reported by authors)
Pantoprazole	RCT, double-blind	USA, multicentre	Efficacy (CSS, biopsies, and endoscopy)	n = 53; 5–11 years	10 vs. 20 vs 40 mg/dies	8 weeks	Tablet	20 and 40 mg were significantly more effective than 10 mg in reducing GER symptoms
	CT, open-label	Mexico, single-centre	Efficacy (24 h pH monitoring, endoscopy)	n = 15; 6–13 years	20 mg (0.5–1.0 mg/kg/dies)	4 weeks	Tablet	Partial clinical improvement of GER symptoms.
Rabeprazole	CT, open-label	USA, multicentre	PK and safety (main PK parameters and evaluation of adverse events)	n = 24; 12–16 years	10 vs 20 mg/dies	1 week	Tablet	10 and 20 mg were well tolerated

N.A, Not available; RCT, randomised controlled trial; CT, clinical trial; PK, pharmacokinetics; PD, pharmacodynamics; CSS, composite symptoms score; dies, daily; bid, twice daily

was available for rabeprazole, its off-label use was considered to be scarcely appropriate in children.

Discussion and conclusions

Of the five authorized PPIs in Europe only one, omeprazole, has a paediatric indication. Consequently, any use of PPIs for the treatment of GERD in patients under the age of 2 years and the paediatric use of all PPIs but omeprazole in patients between 2 and 17 years are to be considered off-label in the EU. Our findings also highlight the discrepancies between regulatory agencies in terms of approved indications (i.e. PPIs for the treatment of GERD in children). Wide discrepancies between the EU and the USA were observed regarding paediatric indications of three compounds, esomeprazole, lansoprazole and pantoprazole. Whereas esomeprazole and lansoprazole are only authorised by the FDA for the treatment of GERD in children aged 1–17 years, pantoprazole was recently reviewed in terms of children posology only in the EU. This heterogeneity could be overcome through the integrated efforts of different regulatory authorities to share more information on the regulatory decision-making process for paediatric drugs. In addition, the incoherence between the posology section and the clinical indication section of the same SPC represents potentially misleading information for prescribers.

According to our analysis, omeprazole, esomeprazole and lansoprazole showed a satisfying level of clinical evidence for paediatric use in the age ranges that are not covered by a formal indication. Those compounds fulfilled all of the criteria for a high appropriateness for administration in children.

A robust clinical data package, i.e. at least two efficacy and two PK trials, and a comparable safety profile between children and adults represent the required level of evidence for avoiding that further paediatric trials are carried out solely for registration and regulatory purposes. This is also in line with the EMEA recommendations on clinical drug development [37–39]. Analysing the available clinical data prior to conducting further trials could be one approach for avoiding the well-known practical and ethical problems related to testing drugs in children. Even when the clinical data package is not robust enough, as in the case of pantoprazole, further testing could be limited only to the missing information.

The case of omeprazole and rabeprazole, respectively evaluated as highly and scarcely appropriate in children, raises further research questions and ethical concerns. In fact, the amount of information available for omeprazole makes the performing of further trials on a molecule of the

Table 3 Appropriateness of off-label use of PPIs in children with GERD

Criteria used for classification of appropriateness	Drugs				
	Omeprazole	Lansoprazole	Esomeprazole	Pantoprazole	Rabeprazole
Availability of clinical trials for efficacy	Yes	Yes	Yes	Yes	No
Availability of PK data	Yes	Yes	Yes	No	No
Comparability of safety profile in children versus adults	Yes	Yes	Yes	Yes	No
Appropriateness	High	High	High	Moderate	Scarce
Comments	The available evidence supports the use in children aged 0–2 years	The available evidence supports the use in children	The available evidence supports the use in children	Pharmacokinetic studies should be conducted to support use in children	Insufficient evidence available in children

same class, such as rabeprazole, useless and unethical unless within comparative trials.

It is often reported that the lack of clinical trials in children can be attributable to ethical, methodological and financial issues. However, our analysis shows a different scenario: although there is a consistent amount of published paediatric trials for this specific condition, the use of PPIs for GERD is still considered off-label. Our study also showed the existence of a large amount of clinical evidence on the use of PPIs in children and, therefore, that performing trials in children is feasible.

We believe that the evaluation we carried out on the appropriateness of off-label use of PPIs in children could be easily extended to other classes of drugs or other special populations. Similar analyses could be helpful for prescribers. This would at least allow a more evidence-based approach to off-label prescribing. Moreover, this model could help regulatory authorities identify research priorities for a specific compound (e.g. a further PK study) and require specific mandatory studies for those important questions of efficacy or safety which still remain unresolved. However, most of the retrieved trials were not RCTs and were based on small sample sizes. Regulatory bodies should promote and support the conducting of few large and well-designed trials instead of a multiplicity of small trials with weak methodology. This could contribute to a better protection of the patients from the potential hazards of the off-label use of drugs.

There are two main limitations to our analysis. Firstly, the evaluation of safety in children for each compound was based on information retrieved in published studies (i.e. clinical trials, reviews, observational studies). Given the small number of patients enrolled in clinical trials, only the more frequent

events could have been observed and reported in each trial. Secondly, we identified the heterogeneity of formulations used as a potential limitation. However, such heterogeneity is a common problem in studies involving children.

In conclusion, the use of medicines that have not been studied and assessed fully in children is a common situation in Europe as well as the rest of the world.

This study was prepared from a public health perspective. A review of the literature with the aim of searching out published findings can be a useful tool for regulators and policy-makers within the framework of granting children simplified access to medicines. Translating clinical evidence into clinical practice and health-care decision-making could be a useful strategy to fill the gap between regulatory bodies and patients, thereby ensuring an equal and quicker access to medicines.
