### 1 Abstract

Б

2 To investigate cation adaptation and homeostasis in Aspergillus nidulans, two transcription 3 factor-encoding genes have been characterised. The A. nidulans orthologue crzA of the 4 Saccharomyces cerevisiae CRZ1 gene, encoding a transcription factor mediating gene 5 regulation by  $Ca^{2+}$ , has been identified and deleted. The *crzA* deletion phenotype includes extreme sensitivity to alkaline pH, Ca<sup>2+</sup> toxicity and aberrant morphology connected with 6 7 alterations of cell wall-related phenotypes such as reduced expression of a chitin synthase 8 gene, chsB. A fully functional C-terminally GFP-tagged form of the CrzA protein is apparently excluded from nuclei in the absence of added Ca<sup>2+</sup> but rapidly accumulates in 9 nuclei upon exposure to  $Ca^{2+}$ . In addition, the previously identified *sltA* gene, having no 10 identifiable homologues in yeasts, was deleted and the resulting phenotype includes 11 considerably enhanced toxicity by a number of cations other than Ca<sup>2+</sup> and also by alkaline 12 13 pH. Reduced expression of a homologue of the S. cerevisiae P-type ATPase Na<sup>+</sup> pump gene 14 ENA1 might partly explain cation sensitivity of null sltA strains. Up-regulation of the homologue of the S. cerevisiae vacuolar  $Ca^{2+}/H^+$  exchanger gene VCX1 might explain the lack 15 of Ca<sup>2+</sup> toxicity to null *sltA* mutants whereas down-regulation of this gene might be 16 responsible for Ca<sup>2+</sup> toxicity to null crzA mutants. Both crzA and sltA encode DNA-binding 17 18 proteins and the latter exerts both positive and negative gene regulation.

### Introduction

1

2

3 Rapid adaptation to different environmental conditions, including appropriate adaptive 4 responses to various cations, is crucial for the survival and proliferation of microorganisms. 5 The Ca<sup>2+</sup>/calcineurin/Crz1p signalling pathway is necessary for adaptation to diverse 6 environmental conditions including high cation levels and alkaline pH, and considerable 7 characterization of it has been achieved in the yeasts Saccharomyces cerevisiae, 8 Schizosaccharomyces pombe, Torulaspora delbrueckii and Candida albicans [1-4]. Sudden 9 exposure of S. cerevisiae to these stress conditions induces a transient increase in cytosolic 10 Ca<sup>2+</sup> levels which triggers activation of the phosphatase calcineurin through binding of the Ca<sup>2+</sup>-binding protein calmodulin. S. cerevisiae calcineurin, like that of mammals is composed 11 12 catalytic and regulatory subunits [5]. Activated calcineurin of both mediates 13 dephosphorylation of the cytoplasmically localised transcription factor Crz1p, resulting in its 14 translocation to the nucleus ([6]; reviewed in [3]).

15 The nuclear localised zinc finger Crz1p transcription factor then activates expression 16 of genes whose promoters contain physiologically relevant <u>calcineurin-dependent</u> response 17 elements (CDREs) [7] 5'-GNGGC(G/T)CA-3, and up-regulates expression of various target 18 genes, including some encoding cation transporters acting at the plasma membrane or other 19 membranous organelles [8-10]. Previously we found that alkaline pH-induced up-regulation 20 of the Aspergillus giganteus afp gene encoding the antifungal protein can be prevented by 21 FK506, an inhibitor of calcineurin [11]. To pursue *afp* regulation in the context of cation 22 adaptation and homeostasis, we have chosen to investigate calcium-mediated signalling in 23 Aspergillus nidulans, an experimentally more amenable species than A. giganteus.

24 Calcium-mediated signalling has been less investigated in filamentous fungi than in 25 yeasts although some notable work was done on calcineurin (reviewed in [12]) which has been revisited recently [13]. It was initially reported that the A. nidulans gene encoding the 26 27 calcineurin catalytic subunit is essential and required for cell cycle progression [14;15]. 28 However, very recently an A. nidulans  $\Delta cnaA$ , deleted for the calcineurin catalytic subunit, 29 mutant strain was found to be viable and display a phenotype similar to that observed for the 30 corresponding Aspergillus fumigatus ( $\Delta calA$ ) mutant strain, which has severe defects in 31 growth extension, branching and conidiophore development [13]. In addition to having abnormal morphogenesis, the A. fumigatus  $\Delta calA$  mutant is also impaired in virulence 32 33 [16;17]. In Aspergillus oryzae calcineurin is required for adaptation to elevated temperature, 34 high Na<sup>+</sup> levels and alkalinisation [18]. Crz1p orthologues have been recently characterised in 35 the filamentous fungi A. fumigatus and Botrytis cinerea, where they play major roles in 36 tolerance to certain cations [13:19].

Another transcription factor important for cation adaptation and homeostasis is SltA. 37 38 An A. nidulans mutation, designated sltA1, resulting in toxicity by high levels of Na<sup>+</sup> and K<sup>+</sup> 39 was described a number of years ago [20]. Subsequently, cloning of the *sltA* gene by 40 complementation of the *sltA1* mutation showed that it encodes a protein containing three 41 Cys<sub>2</sub>His<sub>2</sub>-type zinc fingers and exhibiting significant similarity to the Ace1 transcriptional 42 repressor of cellulase and xylanase genes in *Hypocrea jecorinia* (Trichoderma reesei) [21]. 43 Although O'Neil et al (2002) showed that the *sltA1* mutation results from a premature stop 44 codon just downstream of the third zinc finger of the predicted protein, they did not 45 investigate the role of the SltA protein in cation tolerance, nor did they determine whether 46 *sltA1* has a null phenotype.

Here we characterise aspects of the role of the *A. nidulans* transcription factors CrzA,
a homologue of *S. cerevisiae* Crz1p, along with SltA, which has no identifiable *S. cerevisiae*homologue, but, like CrzA, is involved in cation adaptation and homeostasis. We show that
both CrzA and SltA are capable of binding DNA and that SltA acts positively on transcription
of the Ena1p-like sodium pump *enaA* and negatively on transcription of the putative vacuolar

3

1  $Ca^{2+}/H^{+}$  exchanger *vcxA*. The negative regulation of *vcxA* by SltA is opposed by its 2 transcriptional activation by CrzA and the positive regulation by CrzA is the over-riding 3 factor as *vcxA* mRNA levels in a mutant lacking both of the transcription factors are 4 indistinguishable from those in a mutant lacking only CrzA. Exposure to calcium elicits 5 nuclear localization of CrzA.

### 1 Experimental

### 3 Strains, growth conditions, molecular techniques and phenotype analysis

4 A. nidulans strains used are listed in Table 1. Escherichia coli strains DH5a (Gibco BRL) and 5 XL10-Gold® (Stratagene) were used as hosts for the maintenance of the plasmids listed in 6 Supplementary Table 1. General cloning procedures in E. coli were followed. Standard 7 growth media for A. nidulans, genetic techniques and phenotype testing followed those 8 described previously ([22] and references therein). Gene symbols are described in [23]. 9 Reversion alleles of *sltA1* were selected in a UV-mutagenised strain of genotype *halA24 inoB2 sltA1* as enabling growth on appropriately supplemented complete medium containing 10 11 (final concentration) 1 M NaH<sub>2</sub>PO<sub>4</sub>, and their phenotypes were determined in a selection of 12 outcrossed strains. A. nidulans transformation followed ([22] and references therein). A. 13 nidulans total RNA and genomic DNA preparation as well as Northern and Southern analyses 14 followed standard procedures.

15

2

### 16 Identification of the crzA gene

17 The CrzA homologue in the A. nidulans genome was identified by Blastp searches using the S. cerevisiae Crz1p sequence. On the basis of sequence conservation and apparently similar 18 19 function, AN5726 was named crzA. The position of the predicted intron within the crzA gene 20 was verified by RT-PCR and is in agreement with GenBank entry AB259568. Strain J734 was 21 grown in liquid minimal medium and exposed for two hours to 1 M NaCl after which total 22 RNA was obtained. Total RNA treated with DNase I (FPLC pure, Amersham Biosciences) 23 was used as template for the RT-PCR reaction. First strand synthesis used primer CrzA-9 rev (Supplementary Table 2) and ArrayScript <sup>™</sup> Reverse Transcriptase (Ambion). The following 24 25 PCR performed with primers CrzA-8 fw and CrzA-9 rev yielded full length crzA cDNA which was cloned into plasmid pGEM-T-Easy (Promega) giving plasmid pGEM-T-26 27 CrzAcDNA. The insert was subsequently sequenced using primer walking.

28

### 29 Deletion of crzA

The crzA deletion cassette was constructed as gene replacement cassette comprising the pyr-4 30 gene of Neurospora crassa as selection marker flanked by 1.5 kb of 5' and 3' untranslated 31 32 regions of the crzA gene. The 5' untranslated region of crzA was amplified by PCR using 33 genomic DNA from strain J734 and primers crznulo-1 and crznulo-2, which introduced a NotI 34 and a BamHI restriction site, respectively. The resulting PCR fragment was digested with NotI 35 and *BamH*I and inserted into pBluescriptSK(+) (Stratagene) giving plasmid pBSKpromCrzA. 36 The pyr-4 selection marker obtained from plasmid pFB6 [22] by BglII digestion was inserted into BamHI-linearized pBSKpromCrzA yielding plasmid pBSKpromCrzApyr4-fw. Correct 37 38 orientation of the pyr-4 gene was verified by PCR and restriction analysis. The 3' untranslated 39 region of crzA was amplified by PCR using genomic DNA from strain J734 and primers 40 crznulo-3 and crznulo-4. The resulting PCR fragment was inserted into pGEM-T-Easy and 41 excised using EcoRI digestion. The EcoRI fragment was inserted in the correct orientation 42 into pBSKpromCrzApyr4-fw via the *EcoRI* restriction site. The final plasmid harbouring the 43 6.2 kb crzA deletion cassette was named pBSKdeltaCrzA. This cassette was amplified by 44 PCR using primers crzAnulo1 and crzAnulo-4 and used to transform A. nidulans strain 45 MAD1425. Pyrimidine prototrophic transformants were screened for the crzA deletion by Southern and PCR analysis and strain BER02 was selected for further work. 46

47

### 48 **Deletion of sltA**

49 A cassette comprising the *A. fumigatus riboB* gene fused to the upstream and downstream 50 untranslated regions (UTRs) of *sltA* was used for transformation to delete the *sltA* coding

51 region. A 1.5kb 5'-UTR region of *sltA* was amplified using primers sltnul1 and sltnul2, which

Licenced copy. Copying is not permitted, except with prior permission and as allowed by law. © 2008 The Authors Journal compilation © 2008 Biochemical Society

1 included a NotI and a BamHI restriction site, respectively. The PCR fragment was digested 2 with NotI and BamHI and cloned into the same restriction sites in the pBluescriptSK(+) 3 (Stratagene) plasmid to give pBS-SltA5'. A 1.5kb 3'-UTR region of *sltA* was amplified using 4 primers sltnul3 (inserting an *EcoRI* restriction site) and sltnul4 (carrying a *XhoI* site). The 5 PCR fragment was digested with EcoRI and XhoI, and ligated to pBS-SltA5' to give pBS-6 SltA5'3'. The *EcoRI* 1.9 kb fragment containing the *A. fumigatus riboB* coding region plus 5' 7 and 3' UTRs was obtained from plasmid p1548, and ligated to plasmid pBS-SltA5'3' digested 8 with EcoRI to give pBSdeltaSltA. pBSdeltaSltA was digested with NotI and XhoI to yield the 9 deletion cassette. The *sltA* null strain was made using MAD1427 as recipient strain selecting 10 for transformants able to grow in the absence of riboflavin. Riboflavin prototrophs were analysed by Southern blot and one transformant carrying the desired insertion was used for 11

12 further work.13

### 14 GFP tagging of CrzA

15 Construction of an A. nidulans strain expressing CrzA::GFP followed the methodology described in [24], taking advantage of recently available strains deficient in heterologous 16 17 recombination [25]. 1.5 kb from the most 3' end of the gene and the 3'-UTR region were 18 amplified with primers pairs CrzA1/CrzA2 and CrzA3/CrzA4, respectively, (see Supplementary Table 2) and fused in a 3-way PCR with a fragment, amplified with primers 19 20 CrzA-GFP1 and CrzA-GFP2, containing the gfp gene together with the selectable pyrG gene 21 of A. fumigatus [24]. The fusion cassette was transformed into MAD1732 following the 22 protocol described in ([22] and references therein). Pyrimidine prototrophs were selected and 23 homokaryotic transformants were analysed by Southern blot for single copy integration of the 24 gene replacement cassette.

25

### 26 Gene expression analyses

27 Steady state mRNA levels of the Aspergillus nidulans ENA1-like genes were detected using 28 specific, PCR-amplified, genome probes: For AN6642 a probe of 1357 bp using primers 29 An6642rev and An6642fw covering 40% of the ORF was used For AN1628 a probe of 948 bp 30 using primers An1628rev and An1628fw covering 29% of the ORF was used. For AN10982 a 31 probe of 1295 bp using primers An10982rev and An10982fw, and covering 37% of the ORF 32 was used. To detect AN0471 (designated vcxA), a 926 bp fragment using primers An0471rev 33 and An0721fw, covering 65% of the ORF, was synthesised. For chsB detection (AN2523), a 34 fragment of 719 bp was amplified using primers An2523rev and An2523fw, covering 30% of 35 the ORF. Actin transcript detection used as probe the fifth exon, amplifying the genomic 36 DNA with primers Anid-AcnA and Anid-AcnB. For oligonucleotide sequences see 37 Supplementary Table 2. 38 Northern analyses used total RNA extracted from wild type and mutant strains grown in

- 39 minimal medium (MMA) adjusted to pH 6.5, containing 1% glucose and 10 mM  $NH_4^+$  [as the
- 40 (+)-tartrate] as main carbon and nitrogen sources, respectively. For investigating the various
- 41 cation effects, after 18 hrs of culture at 37°C the indicated additions and pH alterations were
- 42 made with further incubation as specified in the figure legends.
- 43 Quantification of enaA and acnA transcription was done exposing the filters to a
- 44 Phosphorimager screen (Molecular Dynamics) and developing with a FLA-5100 Reader
- 45 (Fujifilm Global). Band intensities were measured using Multi-Gauge V3.0 (Fujifilm Global)
- 46 software.

47

### 48 Construction of GST::CrzA and GST:: SltA fusion proteins

- 49 The plasmid pGEX-CrzA123(469-603) was constructed to express a GST fusion protein 50 containing the complete zinc-finger region of CrzA (aa 469 - 603). The zinc-finger region of
- 50 containing the complete zinc-ringer region of CIZA (aa 409 003). The zinc-ringer region of 51 crzA was amplified by PCR using genomic DNA of strain J734 as template and primers

1 CrzA-ZF-fw-BamHI and CrzA-ZF-rev-EcoRI. Both oligonucleotides introduced the 2 restriction sites for BamHI and EcoRI that allowed in-frame ligation of the PCR fragment into pGEX-2T (Amersham Biosciences). The final plasmid was named pGEX-CrzA(469-603). 3 4 The plasmid expressing a GST::SltA(381 - 549) fusion protein was constructed by cloning a 5 PCR amplicon obtained from J734 genomic DNA with oligonucleotides SltA-ZF-fw-BamHI 6 and SltA-ZF-rev-EcoRI (amplifying the entire zinc finger region of the sltA gene and 7 introducing BamHI and EcoRI sites) into pGEX-2T. The resulting plasmid was named pGEX-8 SltA(381-549). Fidelity and correct orientation of the inserts were verified by sequencing. 9 Fusion proteins were expressed in E. coli DH1 and purified by glutathione affinity 10 chromatography according to the manufacturer's instructions (Amersham Biosciences).

11

Б

### 12 Electromobility shift assays

Synthetic double-stranded oligonucleotides were generated as described in [26]. *A. giganteus* sites *afp*-CDRE-5 and *afp*-SLTA-1 were obtained annealing oligonucletides CDRE-5 with CDRE-5(-) and SltA-1 with SltA-1(-), respectively. *T. reesei* probes 2C and 2C4 were obtained annealing oligonucleotides Ace1-2C-1 with Ace1-2C-2 and Ace1-2C4-1 with Ace1-2C4-2, respectively. For the *A. nidulans chsB* CDRE-1 site, oligonucleotides Chs-CDRE-1fw and Chs-CDRE-1rev, were annealed (for oligonucleotide sequences see Supplementary Table 2).

- 20 Synthetic probes were labelled by end-filling using Klenow polymerase in the presence of a minimum details  $d_{21}$  minimum details  $d_{21}$  by  $d_{22}$  by d
- mixture containing dGTP and  $[\alpha^{-32}P]dCTP$ . Binding reactions were performed as described previously [26]. The binding reaction mixture (final volume 20  $\mu$ l) contained binding buffer
- (25 mM HEPES-KOH, 50 mM KCl, 5 mM MgCl<sub>2</sub>, 0.1 mM EDTA, 1 mM DTT, 20%
   glycerol; pH 7.9), 1 ng labelled double-stranded oligonucleotides, 3 µg non-specific
- 25 competitor [poly(dI-dC) or poly(dA-dT)] and variable amounts of proteins, as purified GST or
- 26 GST::CrzA(469-603) fusion, or as *E. coli* protein extracts for GST::SltA(381-549). Various
- amounts, as indicated in figures or legends, of unlabelled double-stranded oligonucleotides as
- specific competitors, were added to the reaction mixtures before the addition of protein.
  Reaction mixtures were kept on ice for 30 min and DNA and DNA-protein complexes were
  separated on native 5% poly-acrylamide gels. Gels were dried and autoradiographed.
- 30 s 31

### 32 AFP susceptibility testing

Determination of the sensitivity of *A. nidulans* strains to the antifungal protein AFP followedthe protocol of [27].

35

### 36 Microscopy

37 Conidia of A. nidulans strains were grown in appropriately supplemented liquid minimal 38 medium placed on cover slips. Germlings adhering to cover slips were observed using an 39 Axioskop 50 (Zeiss) equipped with a Camedia Digital Camera C-4000 Zoom (Olympus, 40 Hamburg). Light images were captured with a 40 x objective. Images were processed using 41 Adobe Photoshop 6.0 (Adobe Systems Inc.). Observations of Aspergillus fluorescent strains 42 were done in "watch minimal medium" (WMM) as described in [28]. The Aspergillus strain 43 expressing CrzA::GFP was cultured on the surface of glass bottom petri dishes immersed in 44 2.5 ml of appropriately supplemented WMM at 25°C during 16 h. Media were replaced by 45 fresh WMM containing either with or without 10 mM CaCl<sub>2</sub> and the green fluorescence was 46 observed using a Leica DMI6000b inverted microscope, equipped with a GFP specific filter (Ex.470nm; Em. 525nm), and recorded with an Orca-ER camera (Hamamatsu) driven by 47 48 Metamorph (Universal Image Co.)

### 1 Results

# 2 3 Identification of the *crzA* gene.

The putative *A. nidulans* homologue of *S. cerevisiae CRZ1*, AN5726.3 denoted *crzA*, was identified by Blastp searches using the full-length Crz1p protein sequence. The *in silico* predicted cDNA sequence of *crzA* was verified by sequencing a RT-PCR product obtained from total RNA.

8 CrzA and Crz1p share 66% identity within the putative DNA binding domain which 9 comprises three zinc fingers, the first two of which conform to the Cys<sub>2</sub>-His<sub>2</sub> consensus 10  $[(Y/F)XCX_{2.4}CX_{3}(Y/F)X_{5}LX_{2}HX_{3.4}H]$  (Figure 1A). This degree of sequence conservation 11 suggests that CrzA and Crz1p might bind the same DNA target sequence. The third finger of 12 Crz1p and its homologues, including CrzA, appears to have an atypical Cys<sub>2</sub>-His-Cys 13 structure with unusual spacing (Figure 1A) and is currently under study. The 730-residue 14 CrzA protein, in common with its homologues, contains the DNA binding domain in its C-15 terminal moiety. CrzA contains two overlapping putative calcineurin docking domains (CDD) 16 (Figure 1B) whereas Crz1p which is activated by dephosphorylation by the calcineurin 17 phosphatase is thought to contain a single specific recognition sequence PxIxIT [29-31]. 18 Putative Crz1p orthologues are widely distributed amongst the fungi with sequence 19 conservation notably high amongst filamentous fungi (Figure 1C and Supplementary Figure 20 1). The *crzA* transcript appears to be expressed at a very low level by northern analysis but is increased somewhat by exposure to 100 mM  $Ca^{2+}$  for periods of 5-30 min (data not shown). 21 In contrast, no increase in *A.fumigatus crzA* transcript levels was reported in response to 10 or 22 23 60 min exposure to 200 mM  $Ca^{2+}$  [13]. The very modest increase in *crzA* transcript levels in response to Ca<sup>2+</sup> suggests that regulation might be mainly post-transcriptional, particularly in 24 view of the effect of  $Ca^{2+}$  on CrzA localisation (see below). 25

26 27

### The phenotype of a crzA null mutation.

To assess the physiological role of CrzA, a strain deleted for *crzA* was constructed by gene replacement using the *Neurospora crassa pyr-4* gene as selectable marker, as described in Experimental. The original transformant and outcrossed  $\Delta crzA$  strains are, like the corresponding deletion mutants of *A. fumigatus* and *B. cinerea* [13;19], strongly inhibited by elevated Ca<sup>2+</sup> concentrations and alkaline pH (Figure 2), thus resembling the behaviour of *crz1* mutants [9;32] but much more extreme.

34 Strains deleted for crzA have delayed germination in minimal medium in which  $Ca^{2+}$  is present only as a trace contaminant (Figure 3A). The presence of 100 mM Ca<sup>2+</sup> causes hyphal 35 hyperbranching in  $\Delta cr_z A$  strains (Figure 3B). Similar morphological abnormalities have been 36 37 noted for the corresponding A. fumigatus and B. cinerea deletion mutants [13;19]. 38 Interestingly  $\Delta crzA$  strains show significant resistance to the toxicity of the antifungal protein 39 AFP (Figure 3C), recently shown to inhibit chitin biosynthesis, very probably as a result of 40 inhibition of chitin synthases of classes III and V [33]. In contrast, *AcrzA* strains show slight 41 hypersensitivities to other cell wall perturbing compounds such as caspofungin and congo red 42 (data not shown), further suggesting a role for CrzA in determining cell wall structure. Cell 43 wall abnormalities have also been reported for the orthologous B. cinerea crz1 deletion 44 mutant [19]. The similarities in phenotype between null crzA and null chsB A. nidulans 45 strains, which lack a class III chitin synthase [34;35], suggested that *chsB* might be under CrzA control. Figure 3D shows that whereas transfer to medium containing 100 mM Ca<sup>2+</sup> 46 elevates transcript levels of *chsB* in wild type, it fails to do so in a  $\Delta crzA$  strain, indicating that 47 up-regulation of *chsB* in response to  $Ca^{2+}$  is CrzA-dependent. In agreement, the *chsB* 48 promoter contains two putative CDRE sites (data not shown) conforming to the Crz1p binding 49

1 site consensus [7]. In contrast to the effect of  $Ca^{2+}$ , 300 mM Li<sup>+</sup> appears to have no effect on 2 *chsB* transcript levels (Figure 3D).

Another target of CrzA regulation is AN0471.3, denoted  $vcxA^{AN0471}$ , which we 3 4 identified as the closest A. nidulans homologue of S. cerevisiae VCX1 using tBlastn and Blastp searches. In S. cerevisiae the vacuolar  $Ca^{2+}/H^{+}$  exchanger Vcx1p mediates import of 5 6 excess cytosolic  $Ca^{2+}$  into the vacuole [36]. VCX1 transcription is negatively regulated by calcineurin in a Crz1p-independent manner [8;37]. Figure 4A shows that vcxA<sup>AN047T</sup> transcript 7 levels are increased by 100 mM Ca<sup>2+</sup> in a CrzA-dependent manner. As a large number of 8 9 calcium-regulated S. cerevisiae genes show a greater transcriptional response at an early time 10 after alkalinisation provokes a transient rise in cytosolic calcium levels than at a later time [6], vcxA<sup>AN0471</sup> transcript levels were monitored at both 30 and 60 min following calcium 11 12 exposure. Indeed, steady-state transcript levels were lower at the later time point (Figure 4A). 13 Expression of VCX1 homologues in A. fumigatus and B. cinerea is also dependent on the 14 respective CRZ1 orthologues [13;19].

15

17

### 16 Subcellular localisation of CrzA.

To analyse the subcellular distribution of CrzA, a mutant crzA allele expressing a C-18 terminally GFP-tagged CrzA was constructed by gene replacement using previously described 19 20 procedures [24;25;38]. The protein CrzA::GFP encoded by the tagged allele appears to be fully functional as no Ca<sup>2+</sup> sensitivity or growth impairment at alkaline pH is observable (data 21 not shown). In the absence of  $Ca^{2+}$  addition and any form of stress, CrzA::GFP is exclusively 22 23 cytosolic, apparently excluded from nuclei (Figure 5). Upon addition of CaCl<sub>2</sub> to a final 24 concentration of 10 mM, CrzA rapidly accumulates in nuclei, eventually depleting the 25 cytoplasm of fluorescence (Figure 5 and data not shown). Thus, as previously described for 26 the CrzA orthologue Crz1p ([6;31;39] and reviewed in [3]), CrzA appears to be subject to an active nuclear export and import machinery, with an increase of cytosolic  $Ca^{2+}$  concentration eliciting its nuclear import (Figure 5). Presumably, as in *S. cerevisiae* [31],  $Ca^{2+}$  activation of 27 28 29 calcineurin results in dephosphorylation of CrzA and consequent loss of nuclear export capability. A. fumigatus CrzA also localises to the nucleus in response to  $Ca^{2+}$  [13] as does B. 30 31 cinerea CRZ1 when expressed heterologously in S. cerevisiae [19].

32

### 33 **Further characterization of** *sltA* **mutations.**

In view of the sensitivity of  $\Delta crzA$  strains to toxicity of the cation Ca<sup>2+</sup>, further characterization of mutations in the *sltA* gene where the *sltA1* allele confers sensitivity to the cations Na<sup>+</sup> and K<sup>+</sup> [20;21;40] seemed warranted. Although SltA homologues are widely distributed in filamentous fungi, we have been unable to detect any in searches of yeast genomes. The *sltA* gene encodes a 698-residue protein containing three Cys<sub>2</sub>-His<sub>2</sub> zinc fingers and the *sltA1* mutation changes tryptophan codon 502, the second codon following that of the last histidine of finger 3, to a stop codon (Supplementary Figure 2A) [21].

41 To determine the phenotype of a null *sltA* allele and to see whether *sltA1* has the null 42 phenotype a deletion allele was constructed by gene replacement using the Aspergillus 43 *fumigatus riboB* gene as selectable maker (Experimental; Supplementary Figure 2B). We have 44 detected no phenotypic differences between  $\Delta sltA$  and sltA1, suggesting that at least some 45 portion of the C-terminal 197 residues is essential to SltA function (data not shown). As seen in Figure 2, the absence of functional SltA results in elevated sensitivity to Li<sup>+</sup>, Cs<sup>+</sup> and Mg<sup>2+</sup> 46 in addition to  $Na^+$  and  $K^+$ , inability to grow at alkaline pH and hypersensitivity to neomycin 47 48 toxicity. In plate tests  $\Delta crzA \Delta sltA$  double mutants have phenotypes which are the sum of the 49 single mutant phenotypes (Figure 2).

50 Although overall conservation of the C-terminal sequence beyond the third zinc finger 51 of SltA is low among putative homologues, tryptophan-502 and the residues immediately

1 downstream from it are highly conserved, suggesting this region might be required for full 2 functionality (Supplementary Figure 2A). To test this possibility, revertants of a *sltA1* strain 3 were obtained, after ultraviolet mutagenesis, as allowing growth in the presence of 1 M 4 NaH<sub>2</sub>PO<sub>4</sub>. As well as reversion in codon 502 to the wild type tryptophan codon, partially 5 functional revertants with codon 502 encoding arginine, leucine, phenylalanine, lysine or 6 cysteine were also obtained (Table 2). Unsurprisingly, the reversion to phenylalanine appears 7 to give the greatest degree of functionality. These reversion data indicate that tryptophan-502 8 is itself an important residue and that one or more additional important residues is/are located 9 C-terminal to it.

10

# 11SltA acts negatively in the control of $vcxA^{\underline{AN0471}}$ and positively in the control of12 $enaA^{\underline{AN6642}}$

13 The  $\Delta sltA$  mutant showed an elevated response to Ca<sup>2+</sup> in  $vcxA^{AN0471}$  transcript levels 14 at both 30 and 60 min and the response is more pronounced at the latter time point (Figure 4B; 15 data not shown for 30 min). However,  $\Delta crzA$  is epistatic to  $\Delta sltA$  in the control of  $vcxA^{AN0471}$ 

16 as in the  $\Delta crzA \Delta sltA$  double mutant there is no response to Ca<sup>2+</sup> in  $vcxA^{AN0471}$  transcript levels

- 17 (Figure 4B), correlating with the fact that  $Ca^{2+}$  inhibition of  $\Delta crzA \Delta sltA$  double mutants is
- 18 very similar to that of  $\Delta crzA$  single mutants (Figure 2).
- 19 Using S. cerevisiae Ena1p, Ena2p and Ena5p in Blastp and tBlastn searches of the A.
   20 nidulans
- 21 (http://www.broad.mit.edu/annotation/genome/aspergillus\_group/Blast.html) three loci whose 22 predicted protein products are closely related to the Ena P-type ATPase sodium pumps, 23 AN6642.3, designated *enaA* [41], AN1628.3 and AN10982.3, were identified (data not 24 shown). We have designated these genes *enaA*<sup>AN6642</sup>, *enaB*<sup>AN1628</sup> and *enaC*<sup>AN10982</sup>. In *S.* 25 *cerevisiae* the Ena transporters are involved in the salt stress response and are required for 26 growth at alkaline pH [42;43].

growth at alkaline pH [42;43].
Expression of *enaA*<sup>AN6642</sup> requires a combination of elevated [Na<sup>+</sup>] and alkaline pH
(Figure 6). We have been unable to detect transcripts for *enaB*<sup>AN1628</sup> and *enaC*<sup>AN10982</sup> in the
conditions or genetic backgrounds shown in Figure 6. Neither 300 mM Li<sup>+</sup> nor 100 mM Ca<sup>2+</sup>
is sufficient to induce expression of any of the *ena* genes (data not shown). Figure 6 shows
that SltA plays a significant, positive-acting role in *enaA*<sup>AN6642</sup> expression. If CrzA plays a
role, it is much more marginal.

33

### 34 CrzA and SltA are both DNA-binding proteins.

The putative DNA-binding domains, containing the entire zinc finger regions, residues 469-603 for CrzA and residues 381-549 for SltA were expressed in *E. coli* as glutathione-Stransferase (GST) fusion proteins. Although purification of GST::CrzA(469-603) using glutathione affinity chromatography was feasible, we did not succeed in purifying GST::SltA(381-549) despite trying several elution conditions (data not shown). Consequently bacterial protein crude extract were used in DNA binding studies.

To characterise the DNA binding ability of GST::CrzA(469-603) probes conforming to the *S. cerevisiae* Crz1p consensus site CDRE [7] were synthesised (Figure 7A). Two putative CDRE sites were identified in the *A. nidulans chsB* promoter and five such sites were identified in the *Aspergillus giganteus afp* promoter, previously suggested to be under the control of the Ca<sup>2+</sup>-calcineurin signalling pathway [11]. CrzA binds to CDRE-1 from the *chsB* promoter and to CDRE-5 from the *afp* promoter (Figures 7B and C), confirming that binding sequences for CrzA and Crz1p are very similar or identical.

Because of the sequence similarity of SltA to *Trichoderma reesei* ACEI in the zinc finger region ([21]), the ability of GST::SltA(381-549) to bind to the previously described 2C and mutant 2C4 probes [44] was tested. In similarity to ACEI binding, SltA binds to the 2C

but not the 2C4 probe (Figure 7D). SltA also binds to the SLTA-1 site from the *afp* promoter,
 which conforms to the 5'-AGGCA ACEI consensus (Figures 7A, D and E).

As the trinucleotide 5'-GGC is common to sequences bound by CrzA and SltA, we tested whether either of the fusion proteins might bind to a site bound by the other. However, we found no evidence for binding of SltA to *afp* CDRE-5 (Figure 7D) or of CrzA to *afp* SLTA-1 (Figure 7E).

### 1 Discussion

Б

2 The two putative transcription factors investigated here are both involved in 3 preventing toxicity of certain cations. In the absence of functional SltA, A. nidulans is abnormally sensitive to toxicity by Na<sup>+</sup>, K<sup>+</sup>, Li<sup>+</sup> Cs<sup>+</sup> and Mg<sup>2+</sup> but not by Ca<sup>2+</sup> whereas the 4 absence of CrzA results in toxicity of Ca<sup>2+</sup>. Transcript levels of the putative vacuolar Ca<sup>2+</sup>/H<sup>+</sup> 5 exchanger gene vcxA in response to high Ca<sup>2+</sup> levels provide a possible explanation for the 6  $Ca^{2+}$  toxicity to  $\Delta crzA$  strains and the lack of  $Ca^{2+}$  toxicity in  $\Delta sltA$  strains. Whereas  $\Delta sltA$ 7 strains show an elevated response to  $Ca^{2+}$  in *vcxA* transcript levels, putatively allowing greater 8 9 vacuolar storage and thus detoxification of  $Ca^{2+}$ ,  $\Delta crzA$  strains apparently show no  $Ca^{2+}$ response at all, putatively resulting in elevated cytosolic  $Ca^{2+}$  levels. The VcxA homologue 10 Vcx1p of S. cerevisiae mediates the vacuolar import of excess cytosolic  $Ca^{2+}$  [36]. One 11 possible factor in cation toxicity in *sltA* null strains is the reduction in induced levels of the 12 putative cation exporter EnaA<sup>AN6642</sup>. The homologous S. cerevisiae plasma membrane 13 14 exporter Enalp enables a detoxification response to Na<sup>+</sup>, Li<sup>+</sup> and alkalinity [42;43].

The presence of three putative SltA/ACEI binding sites 5' to the *enaA* coding region and one such site 5' to the *vcxA* coding region is consistent with SltA regulation of transcript levels of these genes. Five putative CDRE sites lie upstream of the *vcxA* coding region consistent with CrzA transcriptional regulation of *vcxA*. One CDRE site lies upstream of the *enaA* coding region but, in view of the lack of solid evidence that CrzA regulates *enaA*, its significance, if any, is unclear. In any case, further work will be necessary to determine any physiological relevance of these 5' sites.

This work has highlighted significant differences between *A. nidulans* and *S. cerevisiae*. *S. cerevisiae* lacks an identifiable SltA homologue and whereas *S. cerevisiae* Crz1p is not involved in *VCX1* expression but plays a crucial role in *ENA1* expression [9], *A. nidulans* CrzA plays a crucial role in *vcxA* expression (in similarity to findings in *A. fumigatus* and *B. cinerea*) but is hardly involved, if at all, in *enaA*<sup>AN6642</sup> regulation. The role of CrzA in calcium-induced *chsB* expression finds a parallel in *Candida albicans* where calcium stimulation of promoter activity for four different chitinase genes is Crz1p-dependent [45].

A further point of interest is that SltA appears to play both a positive (in  $enaA^{AN6642}$ 29 30 regulation) and a negative (in vcxA regulation) regulatory role with the caveat that we have 31 not yet shown that SltA acts directly on the regulation of the genes in question. The PacC 32 transcription factor, mediating control of gene expression by ambient pH in A. nidulans acts 33 as both an activator and a repressor (reviewed in [46]) but its S. cerevisiae homologue Rim101p exerts positive regulation by repressing transcription of genes encoding other 34 35 transcriptional repressors [47]. Finally we note that at least three transcription factors are 36 necessary for growth of A. nidulans at alkaline pH: PacC (reviewed in [46]), and, as established here, SltA and CrzA. In the case of SltA, at least one pertinent factor is its role in 37 enaAAN6642 expression. 38

#### **TABLE 2:** sltA1 revertant alleles

<i>sltA</i> mutant allele <sup>a</sup>	Change in protein	Change in codon 502
sltA10, 14, 17 and 18	W502R	TGA to CGA
sltA11, 12, 13 and 20	W502L	TGA to TTA
sltA15	W502F	TGA to TTT
sltA16	W502K	TGA to AAA
sltA19	W502C	TGA to TGC

<sup>a</sup> For four mutations, allele numbers were not allocated as reversion was from TGA<sup>502</sup> back to wild-type TTG.

2 3 Figure 1 Sequence analysis of CrzA. (A) Multiple alignment of the zinc finger domain of 4 predicted CrzA homologues from yeast and filamentous fungi. Shown is the zinc finger region 5 containing three C<sub>2</sub>H<sub>2</sub> zinc fingers (zf), each indicated by an open bar. Two paralogues were 6 found in *Candida albicans* (Calb(1) and (2)). Protein alignments were done using the program 7 ClustalX [48]. (B) Alignment of a selected number of Crz homologues showing the putative 8 calcineurin docking domain (CDD). Open rectangles above the alignment indicate the limits 9 of the two putative CDDs in CrzA orthologues from filamentous fungi, which are compared at the right with the CDD present in Crz1p and the consensus established from the CDDs present 10 11 in the NFAT protein [29]. (C) Phylogenetic tree obtained from the full alignment of the 12 Crz1p/CrzA homologues. The phylogenetic tree was built using MEGA 3.0 [49]. The bootstrap value obtained after 10,000 replicates is shown on top of each branch. The scale bar 13 14 indicates relative evolutionary distance. 15 For panels A and B, Residue shading follows BLOSUM32 similarities. Protein sequences are 16 as follows: Anid, Aspergillus nidulans BAE94327; Aory, Aspergillus oryzae BAE57003; 17 Afum, Aspergillus fumigatus EAL88401; Mgri, Magnaporthe grisea XP 359644; Ncra, 18 Neurospora crassa EAA32849; Cglo, Chaetomium globosum EAQ88414; Gzea, Gibberella 19 zeae EAA68022; Cimm, Coccidioides immitis EAS33001; Pnod, Phaeosphaeria nodorum 20 EAT87393; Dhan, Debaryomyces hanseni, CAG84727; Tdel, Torulaspora delbrueckii 21 AAZ04388; Agos, Ashbya gossypii AAS51722; Scer, Saccharomyces cerevisiae CAA95889; 22 Klac, Kluyveromyces lactis CAG99429; Ylip, Yarrowia lipolytica CAG80473; Calb(1), 23 Candida albicans EAK97605; Calb(2), Candida albicans EAK93473; Cgla, Candida

- 24 glabrata CAG62620; Spom, Schizosaccharomyces pombe Q09838.
- 25 26

Figure 2 Phenotypic analysis of *A. nidulans* strains defective for CrzA and/or SltA function. Spores were point-inoculated on agar plates containing minimal medium (MMA, pH 6.5; 1% glucose as carbon source) supplemented with different salts, as indicated, or neomycin (625 ng/ml). Alkaline pH plate (pH ~8) contained 100 mM Na<sub>2</sub>HPO<sub>4</sub>. 200 mM NaCl is a Na<sup>+</sup> control for the alkaline pH medium. Plates were incubated for two days at 37°C. wt: wild-type (strain HHF17a),  $\Delta crzA$  (strain HH17d),  $\Delta sltA$  (strain HH17e),  $\Delta crzA$  $\Delta sltA$  (strain HH17f).

34

Figure 3 Effect of deletion of crzA on germination, morphology, AFP sensitivity and 35 36 expression of the chsB chitin synthase gene. (A) Conidia from strains MAD1425 (wt) and 37 BER02 (AcrzA) were grown on cover slips at 37°C for 6 or 12 h. (B) Strains HFF17a (wt), 38 HHF17d ( $\Delta crzA$ ) HHF17e ( $\Delta sltA$ ) and HHF17f ( $\Delta crzA$ ,  $\Delta sltA$ ) were grown on MMA agar plates in the presence or absence of 100 mM CaCl<sub>2</sub>. Microscope photographs, using 10 x 39 magnification, were taken of the colony edges. (C) 1000 conidia obtained from strains 40 MAD1425 (wt) and BER02 ( $\Delta crzA$ ) were cultivated at 28°C in 150 µl complete medium 41 42 (YPG) in the presence of different AFP concentrations. After 48 h, the optical densities were 43 measured. Mean values of triplicate experiments are shown. (D) chsB transcript levels were 44 determined in strains MAD1425 (wt) and BER02 (AcrzA) treated for 60 min with 100 mM 45 CaCl<sub>2</sub> or LiCl. The untreated controls are indicated by (-). Strains carrying either wt  $crzA^+$  or 46 the AcrzA allele were cultivated in liquid MMA (pH 6.5) for 18 h at 37°C after which CaCl<sub>2</sub> was added to a final concentration 100 mM. After additional cultivation for 30 or 60 min, total 47 RNA was isolated, blotted and hybridised with a chsB probe. Methylene blue-stained 18S 48 49 rRNA served as loading control. 50

**Figure 4 Effects of various genotypes and elevated Ca<sup>2+</sup> levels on** *vcxA* **expression.** (A) *vcxA* transcript levels were determined after 30 and 60 min in the presence (+) or absence (-) of CaCl<sub>2</sub>. wt: strain MAD1425,  $\Delta crzA$ : strain BER02. (B) Expression of *vcxA* was determined at 30 and 60 min (only shown for the latter) after Ca<sup>2+</sup> addition in the following strains: HFF17a (wt), HHF17d ( $\Delta crzA$ ) HHF17e ( $\Delta sltA$ ) and HHF17f ( $\Delta crzA \Delta sltA$ ). The growth and treatment protocol followed that described for Figure 3.

21

7

Б

**Figure 5 Subcellular distribution of CrzA.** An *A. nidulans* strain, MAD2055, expressing OrzA::GFP was grown in WMM at 25°C in glass bottom petri dishes for microscopy. Mycelia were transferred to fresh medium with or without 10 mM CaCl<sub>2</sub> and photographed after 10 min. incubation at 25°C. Nuclei devoid of fluorescence, indicated by arrows, are visible in cells growing in medium without added Ca<sup>2+</sup>. In the presence of Ca<sup>2+</sup>, the nuclei become strongly fluorescent. Images at the bottom show in more detail the fluorescence distribution within the hyphae under both growth conditions. The bar scales indicate 5 µm.

15

16 Figure 6 Effects of various treatments and genotypes on enaA expression. Strains 17 carrying  $\Delta crzA$ ,  $\Delta sltA$ , both or neither were cultivated in liquid MMA (pH 6.5) for 18 h at 18 37°C after which NaCl was added (final concentration 1 M) and/or the pH of the culture broth 19 was adjusted to pH 8 (using NaOH). After an additional cultivation for 60 min, total RNA was 20 isolated, blotted and hybridised with enaA and acnA (actin) probes. The following strains 21 were used in this experiment: HHF17a (wt), HHF17d ( $\Delta crzA$ ) HHF17e ( $\Delta sltA$ ) and 22 HHF17f (*AcrzA AsltA*). Levels of *enaA* transcripts were determined and expressed relative to 23 those of the actin mRNAs.

24

Figure 7 DNA binding capabilities and specificities of CrzA and SltA. (A). Alignment of 25 Crz1p/CrzA and ACEI/SltA DNA binding sites. CDRE consensus sequences 1 and 2 26 correspond to those described in [10] and [7], respectively. The core sequences of these 27 28 binding sites are indicated. Probes CDRE-5 and SLTA-1 are synthetic sites from the 29 antifungal protein promoter (afp) of A. giganteus. Probe 2C is one of the ACEI binding sites 30 found in the T. reeseii cbh1 promoter and 2C4 is a 2C mutant probe as described in [44]. 31 Probe CDRE-1 is a synthetic site from the A. nidulans chsB promoter. (B) CrzA binding to an 32 *afp*-CDRE-5 probe. (C) Binding of CrzA to a CDRE present in the *chsB* promoter. Binding to 33 this site is subject to competition by the same unlabelled probe or the *afp*-CDRE-5 probe. For 34 (B) and (C), numbers at the top of the gel refer to ng of purified protein used in the assay. (D) 35 Binding of SltA to the 2C probe. 1.5 µg of E. coli extract expressing GST::SltA was used in 36 each reaction. Affinity and specificity of binding is shown by competition with 1000x (300ng) 37 of unlabelled probes SLTA-1, CDRE-5, 2C and 2C4. (E) Specific recognition of afp-SLTA-1 38 probe by SltA. Binding of SltA is shown using different amounts (µg) of E. coli crude extract 39 expressing GST::SltA. Purified GST::CrzA does not bind to this probe. 40
