HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Non linear dynamics of Mathieu resonators for resonant gyroscope applications

For the first time, a complete model describing the non linear dynamics of Mathieu resonators is presented in order to study the stability of resonant MEM gyroscopes.

Introduction:

The resonant sensing technique [1] is highly sensitive, has the potential for large dynamic range, good linearity, low noise and potentially low power. However, when scaling sensors down to NEMS, nonlinearities occur sooner [2] restricting the benefits of the resonant sensors. Moreover, for resonant gyroscopes, the frequency of the coriolis forces becomes closer to the resonator frequency. The idea is to investigate the dynamic behaviour of nonlinear Mathieu resonators [3] in order to find the optimum physical conditions for gyroscope designers to maximise the sensors performances.

Device and equations:

The resonant output gyroscope [4] shown in Figure (1), as its name implies, utilizes resonant sensing as the basis for Coriolis force detection. In its simplest form, the device consists of three resonating elements, a proof mass and two resonating sense elements. The dynamics of the device can be described by a series of coupled differential equations. The proof mass dynamics can be described for most part by a classical spring-mass-damper equation (1). The dynamics of the resonators subjected to an axial time-varying Coriolis force is described by a nonlinear partial differential equation (2) with boundary conditions (3) as follows:

$$\frac{d^2 X(t)}{dt^2} + \frac{\delta}{Q} \frac{dX(t)}{dt} + \delta^2 X(t) = \frac{F_e}{M} \quad (1)$$

$$EI \frac{\partial^4 w(x,t)}{\partial x^4} - \left(N + F_c \cos[\delta t] + \frac{ES}{l} \int_0^l \left[\frac{\partial w(x,t)}{\partial x} \right]^2 dx \right) \frac{\partial^2 w(x,t)}{\partial x^2} + c_R \frac{\partial w(x,t)}{\partial t} + \rho S \frac{\partial^2 w(x,t)}{\partial t^2} = \frac{1}{2} \varepsilon_0 \frac{bV^2}{[g - w(x,t)]^2} \quad (2)$$

$$w(0,t) = \frac{\partial w}{\partial t}(0,t) = w(l,t) = \frac{\partial w}{\partial t}(l,t) = 0 \quad (3)$$

Model:

The Galerkin discretization procedure was used in order to represent the solution of Equation 2 in terms of a linearly independent set of basis functions $\phi_n(x)$ where each basis function satisfies the boundary conditions described in Equation 3. This procedure permits transforming the nonlinear partial differential Equation 2 into a finite system of nonlinear Mathieu equations.

Since we are interested in the response of the resonator at resonance when the first mode is dominant, we reduce the system of ordinary differential equations given by Galerkin discretization to a nonlinear Mathieu equation.

A perturbation technique [5] was used in order to obtain two first order non-linear ordinary-differential equations which describe the amplitude and phase modulation of the response and permits the computation of its stability.

Results:

The effect of the Coriolis force frequency in the resonator frequency response at its primary resonance is shown in the Figure (2). We observe the separation of the curve branches when the Coriolis frequency is closed to the resonator frequency. This particular case is treated in Figure (3) for different kinds of resonator behavior. It appears that the quality factor decreases when the angular rate of the microgyroscope increases. Figure (4) shows the effect of the parametric and the nonlinear terms in the periodicity of the resonator response and its amplitude.

Conclusions:

Another limitation for the full scale of a resonant microgyroscope is underlined: the frequency ratio between the proof mass actuation and the resonator sensing. It appears in Figure (5) that the symmetry can be broken between negative and positive Coriolis stress effect when the resonator lose the stability for high coriolis forces amplitude and frequency. The maximum of sensitivity is situated at 0.6 of frequency ratio.
