Abstract

The K$_2$NiF$_4$ phases La$_{1+x}$Sr$_{1-x}$Co$_{0.5}$Cr$_{0.5}$O$_{4+\delta}$ (x=0, 0.15) and La$_{1+x}$Sr$_{1-x}$Co$_{0.5}$Mn$_{0.5}$O$_{4+\delta}$ (x=0, 0.2) have been synthesised and examined by X-ray powder diffraction, thermal analysis, neutron powder diffraction and magnetic susceptibility measurements. Mn$^{3+}$/Co$^{3+}$ and Cr$^{3+}$/Co$^{3+}$ states predominate in the oxidised forms. Structural stability and crystal symmetry are retained under reducing conditions which cause reduction of Co$^{3+}$ into Co$^{2+}$ and the creation of oxide ion vacancies within the equatorial planes of the K$_2$NiF$_4$ structure. Excess oxygen in La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$ is accommodated in the ideal interstitial positions (0, 0.5, 0.25) of the tetragonal structure. these materials depending upon the atmosphere applied. No long-range magnetic order has been observed because of competing AFM and FM interactions in these B-site disordered materials.

Introduction

There are very few reports of perovskite-type oxides containing Co\(^{2+}\) in their B-sites. These phases are often prepared under oxygen-free or reducing conditions due to their susceptibility to oxidation by atmospheric air. Apart from La\(_2\)CoO\(_4\), the presence of Co\(^{2+}\) in perovskite-type oxides is often linked to oxide ion vacancies; La\(_2\)CoO\(_5\), La\(_4\)Co\(_5\)O\(_9\) and LaSrCoO\(_{3.54x}\) \([1-3]\) are examples of such materials where oxide ion vacancies are either ordered or disordered. Octahedral, tetrahedral, pyramidal and even planar coordinations were assigned to Co in these materials, which indicate the flexibility of Co ions to accommodate a wide range of environments. These phases, however, are unstable in air and also have a limited stability under reducing conditions. On the other hand, stoichiometric K\(_2\)NiF\(_4\) phases containing Co\(^{2+}\) or Co\(^{2+}/\)Co\(^{3+}\) mixtures may be converted to oxygen hyperstoichiometric phases via oxidation of some Co\(^{2+}\) to Co\(^{3+}\). This effect has been observed in La\(_2\)Co(M)O\(_{4+x}\) phases \([4-6]\) where the excess oxygen is incorporated into the rock-salt region of the structure as interstitial defects. Oxygen hyperstoichiometry has also been suggested for strontium doped phases (La,Sr)Co\(_{II,III}\)O\(_4\) \([7,8]\), but these materials have not been fully characterized.

This study aimed to utilize the variety of oxidation states and coordination flexibility of cobalt in layered perovskites to achieve oxygen nonstoichiometry (and mixed valency) that is stable in different oxygen partial pressure and temperature environments. Such materials may be of great interest in applications such as electrodes in solid oxide fuel cells and oxygen separation membranes. It has been found that La-Sr-Co-Fe-O K\(_2\)NiF\(_4\) phases \([9]\) containing either Co\(^{3+}\) or Co\(^{2+}/\)Co\(^{3+}\) are able to withstand reducing conditions (10% H\(_2\)/N\(_2\)) up to 1000°C via reduction of Co\(^{3+}\) into Co\(^{2+}\) and formation of highly distorted MO\(_x\) polyhedra; however, the stoichiometric material containing Co\(^{2+}/\)Co\(^{3+}\) (La\(_{1.2}\)Sr\(_{0.8}\)Co\(_{0.5}\)Fe\(_{0.5}\)O\(_4\)) showed no tendency toward oxygen hyperstoichiometry resulting from oxidation of Co\(^{2+}\) to Co\(^{3+}\) \([9]\). Two new materials of this type are reported here: La\(_{1+x}\)Sr\(_{1-x}\)Co\(_{0.5}\)Mn\(_{0.5}\)O\(_{4±δ}\) (x= 0, 0.2) and La\(_{1+x}\)Sr\(_{1-x}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_{4±δ}\) (x=0, 0.15). These materials exhibit a high degree of structural stability either in air or under reducing conditions at elevated temperatures, along with a range of oxygen nonstoichiometry including...
hyperstoichiometry. We have also studied the two-dimensional M-M magnetic exchange interactions in these phases.

Experimental

The materials $\text{La}_{1+x}\text{Sr}_{1-x}\text{Co}_{0.5}\text{Cr}_{0.5}\text{O}_{4\pm\delta}$ ($x=0, 0.15$) and $\text{La}_{1+x}\text{Sr}_{1-x}\text{Co}_{0.5}\text{Mn}_{0.5}\text{O}_{4\pm\delta}$ ($x=0, 0.2$) were synthesized by solid state reactions using high purity $\text{SrCO}_3$, $\text{La}_2\text{O}_3$, $\text{Co}_3\text{O}_4$, $\text{Mn}_2\text{O}_3$ and $\text{Cr}_2\text{O}_3$ as the starting materials (all previously dried at 800°C in air for 12h in order to remove residual water, hydroxide or carbonate). In order to obtain pure $\text{K}_2\text{NiF}_4$ phases, we used a two-step procedure: stoichiometric amounts of starting materials were intimately mixed, pressed into pellets and calcined at 1350°C for 30h under a $\text{N}_2$ atmosphere (as-prepared materials). The samples were then ground and subsequently heated in air (at 750°C for 12h) or flowing 10% $\text{H}_2$/N$_2$ gas (at 750°C for 12h) in order to prepare the “oxidized” and the “reduced” samples, respectively. All syntheses involved standard furnace cooling regimes.

X-ray powder diffraction (XRD) data were collected using a Siemens D5000 diffractometer in transmission mode, employing Cu$\text{K}_{\alpha 1}$ radiation from a germanium monochromator. Neutron powder diffraction (NPD) data were collected at room temperature and 4 K on the D2B diffractometer at the ILL, Grenoble, using a wavelength of 1.594 Å and the HRPT diffractometer at the SINQ, PSI, using a wavelength of 1.494 Å. Rietveld refinement was performed on the powder diffraction data using the GSAS suite of programs [10] employing a pseudo-Voigt peak shape. All refinements required the use of correction for preferred orientation along [001] direction.

Thermogravimetric measurements were performed using a Rheometric Scientific STA 1500 thermal analyzer. Measurements to analyze the reduction behaviour of the oxidized materials were performed on ~30 mg samples heated at 10°C min$^{-1}$ in 10% $\text{H}_2$/N$_2$. Magnetic susceptibility data were collected using a Quantum Design PPMS magnetometer in the temperature range 5-300 K. Zero-field-cooled (ZFC) and field-cooled (FC) data were collected on warming using an applied field of 0.3 T.
Results

Structural Characterization

The phase purity and crystal structures of all the samples were examined by XRD. The data indicated that all materials are single-phase with no evidence of impurities or starting materials. XRD patterns were readily indexed on a body-centred tetragonal unit cell, consistent with a structure related to that of $K_2NiF_4$ (Figure 1). Structural refinements based on XRD data showed that the materials crystallize in the $I4/mmm$ space group; no evidence of peak splitting or systematic broadening, which may indicate a lowering of cell symmetry due to reduction, was observed. However, as expected from X-ray diffraction, the refinements were insensitive to oxygen nonstoichiometry in the reduced materials and the oxide ion sites could be fixed at full occupancy. A summary of the refined unit cell parameters for different samples is given in Table 1.

NPD data collected at room temperature were used to probe more reliably the oxygen content and defect structures of these materials. Refinement results from the data collected from the reduced materials at room temperature are given in Table 2. Unit cell sizes determined from XRD and NPD data (Tables 1 and 2) differ slightly, as is normal, because of the calibration errors inherent in NPD sources. The estimated standard deviations are from the statistics of the refinements and do not include these systematic errors. Profiles and difference patterns from the Rietveld analysis are shown in Figure 2. The oxygen contents are based on formal oxidation states of Co(II), Mn(III) and Cr(III), which are in excellent agreement with refined data (vide infra). Some selected bond lengths are given in Table 3. Refinements were performed adopting the ideal $I4/mmm$ space group; the use of lower symmetry tetragonal and orthorhombic space groups were unsuccessful and confirmed the absence of cation or defect order. It is important to note that the scattering length contrast is such that Co/Mn and Co/Cr ordering would have been easily detectable in these experiments [11]; such B-site cation order has previously been observed in Co-Mn perovskites [12].
Oxide ion vacancies in these materials are disordered and confined to the equatorial (Co/M)O$_2$ planes of the K$_2$NiF$_4$ structure (O1 in Figure 1). An attempt to fit a model in which oxide ion vacancies are distributed between axial and equatorial oxygen sites [13] proved unstable. An associated twisting of the (Co/M)O$_6$ octahedra around the z-axis is observed, which transforms the oxide ions at (0.5, 0, 0) to the split position (0.5, y, 0), similar to that observed in La$_{1+x}$Sr$_{1-x}$Co$_{0.5}$Fe$_{0.5}$O$_{4-\delta}$ [9]. Despite some correlation between thermal parameters and site occupancies, stable refinements were achieved without applying constraints.

Refinements gave the overall stoichiometries LaSrCo$_{0.5}$Cr$_{0.5}$O$_{3.76}$, La$_{1.15}$Sr$_{0.85}$Co$_{0.5}$Cr$_{0.5}$O$_{3.82}$, LaSrCo$_{0.5}$Mn$_{0.5}$O$_{3.74}$ and La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{3.84}$ for the reduced materials. Consideration of these results in conjunction with TG analysis data (Figure 3), in which the oxidized materials were reduced in flowing 10% H$_2$/N$_2$, provided the oxygen stoichiometries of the oxidized materials: LaSrCo$_{0.5}$Cr$_{0.5}$O$_{4}$, La$_{1.15}$Sr$_{0.85}$Co$_{0.5}$Cr$_{0.5}$O$_{4}$, LaSrCo$_{0.5}$Mn$_{0.5}$O$_{4}$ and La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$. In order to confirm oxygen hyperstoichiometry in La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$, NPD data were collected from this sample at room temperature. Profiles and structural data are given in Figure 4 and Table 4, respectively. Refinement supported the presence of interstitial oxygen and was consistent with the composition La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.10(1)}$. The excess oxygen occupies the ideal interstitial sites (0, 0.5, 0.25) of the tetragonal structure (O3 in Figure 1). An associated displacement of the apical oxide ions, related to that of Jorgensen’s interstitial defect model [14], moves apical oxygen atoms from their ideal position at (0, 0, z) to the split position (0, y, z). Incorporation of excess interstitial oxygen in the K$_2$NiF$_4$ structure with retention of tetragonal symmetry has been observed in La$_{1.2}$Sr$_{0.8}$MnO$_{4.27}$ [15]. No evidence of magnetic order was observed in the low temperature NPD data of any sample.

**Magnetic Susceptibility:**

Figure 5(a) shows the temperature dependence of the magnetic susceptibility of the chromium-containing samples. The oxidized materials are essentially paramagnetic, whereas a
distinct divergence between ZFC and FC susceptibilities is observed in the reduced materials, which suggests spin glass behaviour. Plots of the reciprocal of the molar susceptibility against temperature for the reduced samples (Figure 6(a)) suggest a non Curie-Weiss behaviour in the given temperature range. However, the plots display an increase in gradient on cooling which is expected for spin glasses with antiferromagnetic (AFM) interactions [16] or moments which are not temperature independent, as expected for octahedral Co$^{2+}$. Application of the Curie-Weiss law at the extreme parts of the plots provides negative $\theta$ values, which confirms predominantly AFM interactions. Above 200 K, the $\theta$ values are -179.4 and -182.2 for LaSrCo$_{0.5}$Cr$_{0.5}$O$_{3.75}$ and La$_{1.15}$Sr$_{0.85}$Co$_{0.5}$Cr$_{0.5}$O$_{3.825}$ respectively, and the effective moment for both is 3.84 $\mu_B$ per formula unit. The reciprocal susceptibility plots of the oxidized materials also indicate AFM exchange interactions (see Figure 6(a)). Above 200 K, the $\theta$ values are -245.5 and -69.2 and the effective moments are 3.88 $\mu_B$ and 3.80 $\mu_B$ for LaSrCo$_{0.5}$Cr$_{0.5}$O$_{4}$ and La$_{1.15}$Sr$_{0.85}$Co$_{0.5}$Cr$_{0.5}$O$_{4}$ respectively.

Variation of magnetic susceptibility with temperature for manganese-containing samples is shown in Figure 5(b). The oxidized materials also show higher magnetization than the reduced ones. The divergence between ZFC and FC susceptibilities is again suggestive of spin-glass behaviour. The magnetic susceptibility of La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{3.85}$ shows a broad maximum at about 70 K, which is an indication of AFM ordering in this 2D system. However, no evidence of magnetic order has been found in the low temperature NPD data of this sample. A plot of the reciprocal of the molar susceptibility against temperature for LaSrCo$_{0.5}$Mn$_{0.5}$O$_{3.75}$ shows departure from Curie-Weiss behaviour. Again the plot displays decreasing effective moments with negative $\theta$ values on cooling which is expected for spin glasses with AFM interactions (Figure 6(b)). On the other hand, the reciprocal susceptibility plots of the oxidized materials indicate that these materials exhibit exchange interactions which are predominantly ferromagnetic (FM) with positive $\theta$ values and an increasing effective moment as the temperature decreases [16] (see Figure 6(b)).

Discussion
Oxygen stoichiometries based on refined NPD data and TG analysis of chromium-containing samples are very close to the theoretical values corresponding to Co\(^{2+}/Cr\(^{3+}\) in the reduced materials and Co\(^{3+}/Cr\(^{3+}\) in the oxidized materials, i.e. LaSrCo\(_{0.5}\)Cr\(_{0.5}\)O\(_4\), LaSrCo\(_{0.5}\)Cr\(_{0.5}\)O\(_{3.75}\), La\(_{1.15}\)Sr\(_{0.8}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_4\) and La\(_{1.15}\)Sr\(_{0.85}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_{3.825}\). These nominal stoichiometries are therefore adopted. The reduced materials are spin-glass antiferromagnets. This behaviour can be attributed to competing AFM and FM interactions between high-spin Co\(^{2+}\) and Cr\(^{3+}\) ions; according to Goodenough-Kanamori rules for superexchange interactions \([17,18]\), a disordered Co/Cr distribution would result in competing FM (Co–Cr) and AFM (Co–Co and Cr–Cr) interactions. The effective moments for LaSrCo\(_{0.5}\)Cr\(_{0.5}\)O\(_{3.75}\) and La\(_{1.15}\)Sr\(_{0.85}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_{3.85}\) near room temperature (both 3.84 \(\mu_B\)) are consistent with high-spin Co\(^{2+}\) and Cr\(^{3+}\) ions (3.87 \(\mu_B\)), although a higher moment may be anticipated because of the orbital contribution to the magnetic moment expected for high-spin Co\(^{2+}\).

The magnetic behaviour of the oxidized materials can be attributed to weak exchange consistent with Co\(^{3+}\) ions being in the low-spin state. The effective moments 2.88 \(\mu_B\) and 2.80 \(\mu_B\) for LaSrCo\(_{0.5}\)Cr\(_{0.5}\)O\(_4\) and La\(_{1.15}\)Sr\(_{0.8}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_4\) are relatively close to the spin-only values based on high-spin Cr\(^{3+}/Co^{2+}\) and low-spin Co\(^{3+}\) ions. Spin-only moments which are predicted for LaSrCo\(_{0.5}\)Cr\(_{0.5}\)O\(_4\) and La\(_{1.15}\)Sr\(_{0.8}\)Co\(_{0.5}\)Cr\(_{0.5}\)O\(_4\) are 2.74 \(\mu_B\) and 3.12 \(\mu_B\), respectively. Disappearance of the spin glass behaviour in these oxidised materials is supportive of a low spin state of Co\(^{3+}\); presence of Co\(^{3+}\) in the high-spin or intermediate-spin states would produce a ferromagnetic component of interactions \([\text{Co}^{3+} (t_{eg}^4 e_g^2)-\text{Cr}^{3+} (t_{2g}^3 e_g^0)/\text{Co}^{3+} (t_{eg}^5 e_g^{-1})-\text{Cr}^{3+} (t_{2g}^3 e_g^0)]\) which may result in a spin glass state at low temperatures.

The manganese-containing phases have compositions LaSrCo\(_{0.5}\)Mn\(_{0.5}\)O\(_4\) and La\(_{1.2}\)Sr\(_{0.8}\)Co\(_{0.5}\)Mn\(_{0.5}\)O\(_{4.1}\) (oxidized materials) with reduced forms LaSrCo\(_{0.5}\)Mn\(_{0.5}\)O\(_{3.75}\) and La\(_{1.2}\)Sr\(_{0.8}\)Co\(_{0.5}\)Mn\(_{0.5}\)O\(_{3.85}\). Adopting these stoichiometries for the reduced materials suggests the oxidation states Co\(^{2+}/Mn^{3+}\) or Co\(^{3+}/Mn^{2+}\) for Co and Mn in these materials. Based on arguments given by Karen et al \([19]\), and consistency of Co behaviour in similar systems.
(La\textsubscript{1.15}Sr\textsubscript{0.85}Co\textsubscript{0.5}Cr\textsubscript{0.5}O\textsubscript{4} \textsuperscript{−δ} \textit{M} = Fe \textsuperscript{[9]} and Cr), formation of Co\textsuperscript{2+} (rather than Mn\textsuperscript{2+}) under reduction to neutralize oxygen deficiency in these materials is favoured. The presence of the oxidation states Co\textsuperscript{2+} and Mn\textsuperscript{3+} in the reduced materials rationalizes the spin glass state and absence of long-range AFM order in La\textsubscript{1.2}Sr\textsubscript{0.8}Co\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{3.85} since we predict competing AFM and FM interactions, where the Co\textsuperscript{2+}-Co\textsuperscript{2+} interactions are AFM, Mn\textsuperscript{3+}-Mn\textsuperscript{3+} and Co\textsuperscript{2+}-Mn\textsuperscript{3+} interactions are FM/AFM \textsuperscript{[17,18]}.

NPD analysis showed no evidence of cation order in any of the studied materials which is consistent with the absence of Co\textsuperscript{2+}/Mn\textsuperscript{4+} charge states in the oxidized materials; the ordered Co\textsuperscript{2+}/Mn\textsuperscript{4+} state is also unexpected since it would produce long-range FM order \textsuperscript{[20]} which is not observed in this study. This information suggests the Co\textsuperscript{3+}/Mn\textsuperscript{3+} states to be present in LaSrCo\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{4} and La\textsubscript{1.2}Sr\textsubscript{0.8}Co\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{4.1}. The stoichiometric phase La\textsubscript{1.2}Sr\textsubscript{0.8}Co\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{4} has not been characterized in this study but it would be expected to contain a mixture of Mn\textsuperscript{3+}, Co\textsuperscript{3+} and Co\textsuperscript{2+} ions. The excess oxygen content in La\textsubscript{1.2}Sr\textsubscript{0.8}Co\textsubscript{0.5}Mn\textsubscript{0.5}O\textsubscript{4.1} suggests instability linked to the facile oxidation of Co\textsuperscript{2+} into Co\textsuperscript{3+}. However, the absence of oxygen hyperstoichiometry in La\textsubscript{1.2}Sr\textsubscript{0.8}Co\textsubscript{0.5}Fe\textsubscript{0.5}O\textsubscript{4} \textsuperscript{[9]} and La\textsubscript{1.15}Sr\textsubscript{0.85}Co\textsubscript{0.5}Cr\textsubscript{0.5}O\textsubscript{4} under similar oxidation conditions suggests that other factors are also involved.

The predominance of Co\textsuperscript{3+}/Mn\textsuperscript{3+} oxidation states in the oxidized materials means that a low-spin state of Co\textsuperscript{3+} can account for the different magnetic behaviours of the oxidized and reduced materials. The enhanced FM exchange of the oxidized materials can be attributed to FM interaction between low-spin Co\textsuperscript{3+} and high-spin Mn\textsuperscript{3+}; the absence of long range effect and hence the spin glass behaviour at low temperature are due to competition with the AFM nature of the Mn\textsuperscript{3+}-Mn\textsuperscript{3+} interactions. The possibility of low concentrations of Co\textsuperscript{2+} and Mn\textsuperscript{4+} further complicates the magnetic interactions.

The TG data indicate that the studied materials withstand reducing conditions (10% H\textsubscript{2}/N\textsubscript{2}) up to 1000°C with retention of structural stability (as tested by XRD). Excessive reduction in the case of the Co-Mn samples at T > 800°C (Figure 3-b) indicates formation of some Mn\textsuperscript{2+} under these
conditions, with a correspondingly higher degree of oxygen deficiency. The presence of large oxygen nonstoichiometry along with the structural stability at high temperature in reducing environments makes these materials an attractive system to be explored for use as oxygen separation membranes.

Oxide ion vacancies in the reduced materials are located within the equatorial planes of the K$_2$NiF$_4$ structure, which suggests formation of unusual MO$_x$ coordination polyhedra similar to those observed in LaSrCoO$_{3.5+x}$ [3]. Vacancies in these materials are formed via reduction of low-spin Co$^{3+}$ into high-spin Co$^{2+}$ which indicates an associated expansion in the MO$_x$ polyhedra. An expansion in $a$ and $c$ parameters is therefore expected, but expansion of $a$ in these materials is often hindered by the coordination requirements of the A-type (La/Sr) ions (see Table 1). Under reduction, a contraction in La/Sr coordination sphere (achieved in the $xy$ plane, i.e. $a$) occurs due to reduction of coordination number (< 9) [3,9]. This explains the twist of MO$_x$ polyhedra around the $z$-axis in the reduced materials, where a contraction in $a$ is required without significant contraction of the MO$_x$ polyhedra. The effect of interstitial oxygen on the lattice parameters of these materials can also be examined by considering the refined NPD data of La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$ and La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Fe$_{0.5}$O$_4$ [9] and their reduced forms. 3.0% contraction in $c$ and 1.2% expansion in $a$ in case of La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$, compared with 1.8% and 0.2% in case of La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Fe$_{0.5}$O$_4$, occur due to insertion of oxygen in these materials (starting from O$_{3.85}$ phases). Extra contraction of $c$ and expansion of $a$ in La$_{1.2}$Sr$_{0.8}$Co$_{0.5}$Mn$_{0.5}$O$_{4.1}$ are therefore attributed to the interstitial oxygen; the increase of the effective charge of the transition metal ions (to compensate the excess oxygen) can account for the $c$ contraction, while the expansion of $a$ can be attributed to an expansion in the coordination sphere of A ions (La/Sr), achieved also in the $xy$ plane, due to an increase in the coordination number (> 9).

Tables 2 and 3 clearly show a stronger distortion effect in MO$_6$ polyhedra for the manganese-containing samples; this effect is associated with a significant elongation parallel to the $z$ axis (LaSrCo$_{0.5}$Cr$_{0.5}$O$_{3.75}$: $a$=3.83401(4) Å, $c$=12.72734(25) Å, M-O1=1.9220(3) and
M-O2=2.125(2); LaSrCo0.5Mn0.5O3.75: \(a\) = 3.80329(6) Å, \(c\) =13.04087(24) Å, M-O1=1.9076(2) and M-O2=2.2269(9)). This effect is expected for Mn\(^{3+}\) because of its susceptibility to Jahn Teller distortions [21].

Conclusions

La\(_{1+x}\)Sr\(_{1-x}\)Co0.5Mn0.5O\(_{4\pm \delta}\) (\(x = 0, 0.2\)) and La\(_{1+x}\)Sr\(_{1-x}\)Co0.5Cr0.5O\(_{4\pm \delta}\) (\(x = 0, 0.15\)) are new members of mixed-cation \(K_2\)NiF\(_4\) phases. The materials crystallize in the tetragonal \(I4/mmm\) space group and withstand reducing conditions (10% \(H_2/N_2\) up to 1000°C) via reduction of Co\(^{3+}\) to Co\(^{2+}\) and formation of disordered oxide ion vacancies within the basal plane of the \(K_2\)NiF\(_4\) structure. Under oxidizing conditions (air up to 1000°C), excess oxygen is introduced into the Sr-deficient sample containing Mn, forming La\(_{1.2}\)Sr0.8Co0.5Mn0.5O\(_{4.1}\) with interstitial oxygen at (0, 0.5, 0.25) sites of the tetragonal structure. The reason for the inability of LaSrCo0.5Mn0.5O\(_4\) and La\(_{1.15}\)Sr0.85Co0.5Cr0.5O\(_4\) to accommodate interstitial oxygen is not clear, but may relate to subtle redox effects of the B-site cations. Unlike the double perovskite La\(_2\)CoMnO\(_6\) [12], the layered nature of La\(_{1+x}\)Sr\(_{1-x}\)Co0.5Mn0.5O\(_{4\pm \delta}\) stabilizes the Co\(^{3+}/\)Mn\(^{3+}\) state which is converted into the Co\(^{2+}/\)Mn\(^{3+}\) state under reduction; the dominant exchange interactions change from FM to AFM under reduction which is consistent with a low-spin state of Co\(^{3+}\) in these materials. The absence of long range magnetic order in all phases can be attributed to competing AFM and FM interactions which are consistent with the B-site disorder and layered nature of these materials.
