Inventory management practices and their implications on perceived planning performance

ABSTRACT

This paper focuses on the use of material planning methods to control material flow to inventories of purchased items. The first sub-objective is to evaluate the perceived planning performance of material planning methods used to control material flows in different inventory types in manufacturing and distribution companies. The second sub-objective is to evaluate the difference in perceived planning performance depending on the way planning parameters are determined and the methods used. Five material planning methods are studied: the re-order point method, the fixed order interval method, run-out time planning, kanban and MRP. Analysis is based on survey data from 153 manufacturing and 53 distribution companies. Findings conclude that the use of material planning methods differs depending on where along the material flow they are applied, whether the inventory is located in a manufacturing or in distribution operations and between companies of various sizes. The modes of applying a material planning method affect its perceived performance. In particular, the way of determining and the review frequency of safety stocks and lead times have great importance for the planning performance of MRP methods, while the determination and review of order points, review frequencies and run-out times were important for re-order point methods.

Keywords: inventory management, planning environment, planning parameters, materials requirements planning, re-order point, performance

1. INTRODUCTION

This study deals with inventory management practices at the tactical planning level, also known as material planning. It concerns balancing supply and demand – i.e. the initiation, control and monitoring of manufacturing and purchasing orders in order to maintain an uninterrupted material flow and value-adding activity in manufacturing and warehouses. There are a number of material planning methods, which control material flows in different ways, for example the re-order point, fixed order interval, run-out time, kanban and material requirements planning (MRP) methods (e.g. Seetharama et al., 1995, Vollmann et al., 2005). These methods may be more or less appropriate depending on the type of inventory they control, i.e. if they are used for controlling the replenishment stocks of purchased items used in manufacturing, controlling manufacturing or the replenishment of finished goods stocks in distribution operations (Rabinovich and Evers, 2002). Material planning methods can also be considered to perform differently well depending on the environment where they are used (Krajewski et al., 1987, Berry and Hill, 1992, Jonsson and Mattsson, 2003).

Material planning performance is partly a result of whether appropriate methods are employed and whether they are used correctly. For example, a method could be expected to perform better if lead times, safety stocks, re-order points, batch sizes etc. represent reality rather than not. To do this, the parameters may need to be analytically determined (safety stocks calculated from determined service levels etc.) rather than experience-based.

1
2
3 However, studies show that this is not always the case: “Surprisingly, many companies use
4 outdated, simplistic methods for allocating safety stocks, and they do not ever know it”
5
6 (Sandvig, 1998). Wilkinson (1996) writes that “in the last few years, we have worked for
7
8 over 30 clients, in excess of 90% of these did not set mathematically based safety stock
9
10 levels”. Jonsson and Mattsson (2006) conducted a longitudinal study of the use of material
11
12 planning methods in manufacturing companies between 1993 and 2005. They concluded
13
14 that a common way of determining parameters such as order quantities and safety stocks is
15
16 by general judgment and experience. They also concluded that the proportion of companies
17
18 with replanning capability in their Enterprise Resource Planning (ERP) systems has
19
20 increased, but only a minor portion of the companies use automatic replanning.
21
22
23
24
25
26

27 The parameters should also be updated periodically in order to adjust dynamically to the
28
29 changing environment. Furthermore, the planning frequency may have an important
30
31 performance impact, especially in environments characterised of uncertain demand (e.g.
32
33 Lee, 2002) where daily rather than weekly planning would probably result in more
34
35 appropriate plans. The Jonsson and Mattsson (2006) study also showed that parameters
36
37 used in the material planning methods were reviewed rather infrequently, typically once a
38
39 year or less in over half of the companies. For re-order point methods, there was a general
40
41 trend towards less frequent reviewing.
42
43
44
45

46 Consequently, planning performance may be affected by the type of inventory and the
47
48 planning environment where it is used and how parameters are determined in the first place,
49
50 how often they are reviewed or the planning frequency. However, there has been little
51
52 empirical analysis of the performance impacts of the planning environment and the way
53
54 material planning methods are used or how planning parameters are determined.
55
56
57
58
59
60

1
2
3 The first objective of this paper is to evaluate the perceived planning performance of
4 material planning methods used to control material flows in different inventory types in
5 manufacturing and distribution companies. The second objective is to evaluate the
6 perceived planning performance depending on the way planning parameters are determined
7 and the methods used. The analysis is based on survey data.

18 2. FRAME OF REFERENCE

21 2.1 Material Planning Methods for Inventory Management

22 The two essential questions to address in material planning are “When to order/deliver?”
23 and “How much to order?” – i.e. one time-related and one quantity-related. There are a
24 number of material planning methods, which answer these two questions in different ways
25 and can be categorised as working with dependent or independent demand. Materials
26 requirements planning (MRP) is the best known and most widely used method for
27 dependent demand. Re-order point methods (ROP), fixed order interval method (FOI), run-
28 out time planning (ROT) and kanban are common methods for independent demand (see
29 e.g. Vollmann et al., 2005). The run-out time planning method (e.g. Seetharama et al.,
30 1995) is synonymous with the cover time planning method (e.g. Segerstedt, 2006). These
31 five methods are included in this study.

32 Material planning methods have a number of different replenishment mechanisms (re-
33 order points, replenishment intervals, run-out times, number of kanbans and the MRP
34 calculation). However, they also include several common planning parameters, for example
35 safety stocks, lead times and order quantities.

2.2 Inventory Types and Perceived Material Planning Performance

Only a few studies focus on the adoption patterns of material planning methods in different types of inventories. Newman and Sridharan (1992) studied the use of re-order point methods, material requirements planning, kanban and OPT in US manufacturing companies: 56% used MRP, 22% used re-order point methods, and 8% used kanban. In the study by Cervený and Scott (1989) in six different industries, 60% were MRP users. Osteryoung et al. (1986) concluded that a majority of firms used re-order point methods for controlling finished goods inventories compared to work in process and raw materials. This is logical, since the items controlled in the finished goods inventory have independent demand and cannot be derived by exploding and off-setting the demand through the bill-of-materials as done in the MRP method. However, the distribution requirements planning (DRP) and time-phased order point methods are MRP related alternatives to the re-order point related methods in such an environment. An earlier study by Reuter (1978) concluded that 85% of the examined companies used re-order point methods for placing orders with suppliers. The study did not separate purchase of finished products and purchase of items to be used as input to manufacturing. This may explain the heavy use of the re-order point method. It is, however, also logical to believe that the re-order point method is suitable for replenishment of inventories of purchased input items to manufacturing, especially for those that are standard items used for making several different products and therefore have quite even demand and picking frequency in the inventory. There are, however, studies indicating a somewhat different usage pattern in various inventory types. Rabinovich and Evers (2002) showed that MRP was used to a significantly greater extent than re-order

1
2
3 point methods in controlling material flows in raw material inventories, work in progress
4
5 and finished goods inventories. The differences in adoption patterns between the studies
6
7 may to some extent be explained by when they were conducted. Jonsson and Mattsson
8
9 (2006), for example, conducted a longitudinal study of the use of material planning
10
11 methods in 1993, 1999 and 2005. They showed that MRP has strengthened its position as
12
13 the most important material planning method and that the re-order point method decreased
14
15 in importance between 1993 and 1999. The re-order point method is still the secondly most
16
17 used method in industry. The study also showed that kanban has increased in use during the
18
19 last decade.
20
21
22
23

24 The performance of the material planning method can be estimated in different ways.
25
26 Firstly, it should constitute a good basis for achieving high operational performances, in
27
28 terms of costs, tied-up capital and customer service. Secondly, it should be user friendly,
29
30 i.e. easy to understand and use and efficient to operate. Operational performances could be
31
32 expected to be lower if a method is used in an inappropriate environment (e.g. Krajewski et
33
34 al., 1987, Berry and Hill, 1992). Jonsson and Mattsson (2003) explained how material
35
36 planning methods performed in four types of manufacturing environments. MRP performed
37
38 well in processes making complex customer products, but kanban did not. In processes
39
40 configuring products to order, all material planning methods were suitable but MRP had the
41
42 best fit. In batch production of standardised products, the re-order point methods had the
43
44 best fit together with MRP and in repetitive mass production all methods performed well,
45
46 however, kanban had the best fit. It was also identified that batch production of
47
48 standardised products had significantly more satisfied material planning users compared to
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 the other environments, thus, indicating that the material planning difficulties vary between
4 environments.
5
6

7
8 It is also reasonable to assume that planning methods are more or less suitable and
9 perform differently depending on whether they control raw material stocks, work in process
10 or finished goods inventories (Rabinovich and Evers, 2002). Methods based on dependent
11 demand (e.g. MRP) should have their greatest benefits for control of inventories in
12 manufacturing and for controlling inventories of purchased items to be included in
13 manufactured products. Methods based on independent demand (e.g. re-order point
14 methods) should, on the other hand, be most important and perform best for controlling
15 inventories of finished products and purchased items with low value and even demand.
16
17 None of the “traditional” material planning methods make capacity considerations.
18
19 However, there exist advanced planning and scheduling (APS) methods that conduct
20 concurrent priority and capacity planning. The use of APS methods is still low in industry.
21
22 No identified study has analysed the extent of APS use or how the APS related
23 methodology is used and its perceived performance output. This methodology is not
24 included in this study.

43 **2.3 Modes of Application and Perceived Material Planning Performance**

44
45 The performance of a material planning method can also be expected to differ depending
46 on the quality of the planning parameters, i.e. to what extent the parameters are correct
47 representations of reality (Sheu and Wacker, 2001). This may be a result of how the
48 parameters are determined in the first place or how the planning method is used, i.e. how
49 parameters are reviewed, and the modification and planning frequency of the orders.
50

56
57
58
59
60

1
2
3 Determining order quantities is essentially an issue of balancing ordering costs and
4 inventory carrying costs. Various categories of methods to accomplish such a balance can
5 be identified, for example dynamic and fixed quantity models (e.g. Huang, 2000).
6
7
8
9
10 Consequently, the approaches to determining the order quantity have a number of different
11 characteristics that may influence user friendliness and operational performance. Enns
12 (1999), for instance, showed the impact of various fixed order quantities on utilisation,
13 work in process and meeting due dates. The results emphasised the importance of selecting
14 proper batch sizes in MRP. Another study, by Wemmerlöv and Whybark (1984), showed
15 that dynamic lot-sizing models resulted in higher overall performances compared to other
16 models.
17
18
19
20
21
22
23
24
25

26
27 The optimum size of the order quantity is influenced by the current requirements. This
28 means that in order to maintain as optimal order quantities as possible they must be
29 reviewed periodically. How often this should be is an issue of balancing the cost of
30 reviewing them with the benefits of maintaining them closer to the optimum. Experience-
31 based quantities are normally more time consuming and costly to review than calculation-
32 based quantities. However, calculation-based quantities are more dependent on the quality
33 of the basic data in order to produce reliable measures.
34
35
36
37
38
39
40
41
42

43 To protect the material flow from disruptions due to uncertainties in demand and supply,
44 various safety mechanisms can be applied in all of the examined material planning
45 methods. The uncertainty in supply and demand can basically be managed in two ways: by
46 adding quantity buffers (i.e. using safety stock) or by adding time buffers (i.e. using safety
47 time). Whybark and Williams (1976) used simulation studies to conclude that there are
48 strong preferences for using safety lead times in MRP methods where demand or supply
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 timing uncertainty exists, and using safety stocks where there is uncertainty in either the
4 demand or supply quantity. Similar studies and findings relating to MRP methods
5
6 (Molinder, 1997) and fixed order interval methods (Benton, 1991) have been carried out.
7
8

9
10 In most companies safety stocks are determined based on experience or by adding a
11 fixed percentage to the lead-time demand (Jonsson and Mattsson, 2006). Of these
12 approaches the experience-based approach cannot be updated automatically and is therefore
13 more costly to review. Sandvig (1998), for example, states that surprisingly many
14 companies use outdated and simplistic methods for allocating safety stocks.
15
16
17
18
19
20
21

22 Accurate lead times are very important in all material planning methods. This is for
23 instance the case when calculating re-order points in re-order point methods, comparing
24 run-out times with replenishment lead times in run-out time planning, and when off-setting
25 start dates in material requirements planning. Lead times can be based on experience,
26 calculations in the ERP system or monitored actual time. Zijm and Buitenhek (1996)
27 discussed the problem with fixed lead times in MRP methods and compared it with
28 workload-dependent lead times which resulted in significantly higher performance.
29 Experience-based lead times have the same drawbacks as experience-based order quantities
30 and safety stocks.
31
32
33
34
35
36
37
38
39
40
41
42

43 The modes of determining order quantities, safety mechanisms and lead times affect the
44 possibility of obtaining accurate and appropriate measures. The frequency of reviewing the
45 parameters also affects the dynamics of the methods and thereby the operational
46 performance of the material planning (e.g. May, 1999). The review frequency is especially
47 important in situations of varying demand and supply (Zhou and Lee, 1993). The planning
48 frequency and ability of the method to automatically re-plan orders may result in more up-
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 dated parameters and thus having the same impact on operational planning performance.
4

5
6 However, frequent adjustments could also have an augmented effect, often referred to as
7
8 system nervousness. One way of decreasing the nervousness would be to work with longer
9
10 planning periods and by freezing time fences (Tang and Grubbström, 2002). Longer
11
12 planning horizons may actually worsen MRP performance in a situation of uncertain
13
14 demand but improve its performance in a deterministic case (Zhao and Lee, 1993). In
15
16 addition to these general modes of applying methods, there are also method-specific modes
17
18 – for example determination of order points, review periods, run-out times and number of
19
20 kanbans.
21
22
23
24
25
26

27 **2.4 The Study Design**

28
29 The study is designed and analysis conducted in two steps, according to the objectives. To
30
31 achieve high planning performance the material planning methods need to be used in
32
33 appropriate planning environments. Here, we separate three different planning
34
35 environments based on the type of inventory the method controls. The first type concerns
36
37 inventory of purchased items to be used in manufacturing operations. The second concerns
38
39 inventory of manufactured semi-finished goods and the third concerns inventory of
40
41 purchased finished products, i.e. inventories in distribution operations or spare parts. We
42
43 also separate the method use in small and large firms. In accordance with the previous
44
45 discussion, some differences in use and perceived planning performance is expected for the
46
47 respective methods in the different inventory types. This is the first part of the analysis (See
48
49 Figure 1).
50
51
52
53
54
55
56
57
58
59
60

1
2
3 To achieve high planning performance, the planning parameters used in the respective
4 method also have to reflect the conditions in the planning environment. This can be
5 accomplished by estimating them based on general judgement and experience. Setting
6 parameters based on general judgment and experience means, however, that the parameters
7 become very loosely connected to existing environmental conditions. By using analytical
8 methods when determining the planning parameters, such relationships can be more exactly
9 and accurately established. For example, the re-order point can more properly reflect the
10 current lead time and demand if it is determined as the sum of the demand during lead time
11 plus a safety stock rather than using a fixed number. Correspondingly, the safety stock can
12 reflect the current variation in demand and determined service levels if it is analytically
13 calculated rather than assessed as a fixed value.

14
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29 As a result of frequent changes in the planning environment in most industries, planning
30 parameters must also be reviewed and updated for the methods to work correctly. This
31 concerns for instance changes in interest rates, ordering costs, demand, variation in demand
32 and lead times. The need to review and update the parameters regularly is a concern
33 irrespective of whether the parameters are manually estimated or analytically calculated by
34 the ERP system. Frequent parameter updating can, however, be more easily accomplished
35 by analytical methods. If, for example, the re-order point is determined as the demand
36 during lead time plus a safety stock rather than a fixed number, the economic order quantity
37 or other calculation method is used when determining order quantities, safety stock
38 calculations are applied based on determined service levels and lead times are based on
39 calculations in the ERP system, the parameters can automatically be updated when the
40 environment changes.
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Another important concern in achieving high planning performance is planning
4 frequency. More frequent planning results in more updated plans, which in most situations
5
6 should lead to more accurate plans and thus higher planning performance. Less frequent
7
8 material planning means planning with longer intervals, which means longer lead times
9
10 from a planning perspective. This also contributes to increased uncertainty.
11
12

13
14
15 Manually modifying planned orders may have a positive performance impact because it
16
17 could result in the changed order becoming more accurate. However, changes will result in
18
19 alterations to other planned orders which may lead to lower performance. A manual change
20
21 may also negatively affect perceptions of user friendliness.
22
23

24
25 In ERP systems supporting MRP it is often possible to generate re-planning suggestions
26
27 and to automatically re-plan orders. Automatic re-planning overrules the planner, which
28
29 could result in low performance, but is on the other hand more cost efficient than manual
30
31 re-planning.
32
33

34
35 In accordance with the above discussion, the second part of the analysis relates to the
36
37 level of analytically determining parameters and the review frequency, planning frequency,
38
39 order modification and automatic re-planning ability when using the methods (Figure 1)
40
41 and their perceived performance impact. Planning performance is measured as the “user
42
43 friendliness” and “operational performance”. The performance impact is analysed with
44
45 statistical significance tests for the independent demand-oriented methods (re-order point,
46
47 fixed order interval and run-out time methods) as a group and for the dependent demand-
48
49 oriented MRP method. Descriptive data is also presented for the re-order point, fixed order
50
51 interval, run-out time and kanban methods, separately, but the samples are too small to
52
53 conduct statistical significance tests. The independent demand method group will hereafter
54
55
56
57
58
59
60

1
2
3 be denoted re-order point methods, as the methods (are) in several respects are variants of
4 the traditional re-order point method.

20 **3. METHODOLOGY**

21 **3.1 Selection and Data Collection**

22
23
24
25
26
27 Data collection was made by a web-based survey. E-mails about participation in the survey
28 were sent to 573 member companies of the Swedish Production and Inventory Management
29 Society (PLAN), an affiliate of APICS. Of these 573, 153 companies responded, which is a
30 response rate of 31%. We expected most PLAN companies to be in manufacturing and thus
31 to use material planning methods for controlling stocks of purchased and manufacturing
32 items. In order to include companies using material planning methods in distribution
33 operations, the survey was also sent to logistics managers at all Swedish wholesaling
34 companies with more than 20 employees. Addresses were provided by the Swedish postal
35 service: 469 surveys were sent out and 53 useable responses were received, a response rate
36 of 11%. The questionnaire was quite long and some of the respondents from the
37 wholesaling company selection were probably not inventory management experts, which
38 may explain the relatively low response rates. About half of the respondents were from
39 mechanical engineering companies and more than half were large companies (Table 1).

21
22

23
24 Generally speaking, PLAN members are distributed across manufacturing industries
25 according to the average for Swedish manufacturing (i.e. with about half of the companies
26 in the mechanical engineering sector). A reason for sending the questionnaire to PLAN
27 members was that they were likely to have an interest in manufacturing planning and be
28 familiar with the terminology used in the survey. Membership of PLAN is personal.
29 Therefore, we did not expect the studied companies to be more advanced users of planning
30 methods compared to the average for Swedish manufacturing, only that the respondents
31 were more aware of the manufacturing planning and control area compared to the average.
32 For the wholesaling companies, the situation is different. In this case, the survey was
33 addressed to logistics managers. Several different material planning situations and
34 applications could exist in one company, but we have included only one response per
35 company in this analysis. Respondents were requested to answer only those sections they
36 were familiar with and to pass the questionnaire to those in the company most qualified to

10 **3.2 The Survey Instrument**

11
12 There are four types of measures in this study. The first measures the use of the respective
13 material planning method. The second measures the planning environment, here
14 operationalised as inventory type. The third measures the mode of application of a specific
15 planning method, and the fourth measures the perceived performance of the planning
16 methods used. The classifications used and criteria measured follow the general
17 manufacturing planning and control definitions (e.g. Vollmann et al., 2005).
18
19
20
21
22
23
24
25
26

27 In evaluating the use of planning methods, respondents were given four alternatives: (1)
28 the method is not used, (2) the method is used as a complement, (3) the method is used as a
29 main method, (4) don't know. Respondents marking alternatives 2 or 3 were coded as
30 users. "Main method" was defined as the method used for the majority of items.
31
32
33
34
35

36 Here, the planning environment concerns the type of inventory that the method
37 controlled. The respondents were given three alternatives: 1) control of inventories of
38 purchased items to be used in manufacturing operations, 2) control of manufactured semi-
39 finished goods , 3) control of inventories of finished goods or spare parts in distribution
40 operations.
41
42
43
44
45
46
47

48 The modes of application of the studied methods were measured in terms of the
49 following: choice of lot-sizing methods, ways of considering uncertainties, level of
50 analytical determination of re-order points, level of analytical determination of safety
51 stocks and safety times, level of analytical determination of lead times, reviewing
52
53
54
55
56
57
58
59
60

1
2
3 frequency of order quantities, reviewing frequency of safety stocks and safety times,
4
5 reviewing frequency of lead times, and planning frequencies. Some additional planning
6
7 variables were included for run-out time planning and kanban (see Table 2). Answers were
8
9 coded “1” or “2”, in accordance with Table 2. For MRP and re-order point methods, four
10
11 indexes were formed, two for analytical parameter determination and two for parameter
12
13 review frequency. Table 2 shows the definitions of the variables and indexes used for the
14
15 re-order point methods and the MRP method.
16

25

26 -----
27 Insert Table 2 here
28 -----
29
30
31
32

33 Two variables and questions were used to measure the perceived planning performance: (1)
34
35 *User friendliness* (“How easy is the method to understand and use, and how time
36
37 consuming is it?”), and (2) *Operational performance* (“How well does the control of
38
39 inventories and material flows match your expectations, in terms of achieving low tied-up
40
41 capital, high customer service and few shortages?”). The answers were measured on seven-
42
43 point scales, where “1” represented “poor”/“not at all”, “4” satisfactory, and “7” “very
44
45 well”. Previous studies have used the perceived overall performance of manufacturing
46
47 (Safizadeh et al., 1996), the inventory turnover rate (Rabinovich et al., 2003) and inventory
48
49 days on hand in different inventories (Safizadeh and Ritzman, 1997) as measures for
50
51 materials management performance. To validate our two measures of perceived planning
52
53 performance we have included two measures that are in line with those tested and used in
54
55
56
57
58
59
60

1
2
3 previous studies. The first is about the perceived overall inventory turnover rate in relation
4 to the competitors in the industry (measured on a 7 point scale ranging from much lower to
5 much higher) and the second about the perceived overall delivery service performance to
6 customer in relation to the competitors in the industry (measured on a 7 point scale ranging
7 from much worse to much better). These validity tests are explained in the next section.
8
9
10
11
12
13

14 15 16 17 18 **3.3 Reliability and Validity**

19 To increase the reliability and validity of the questionnaire, it was pre-tested and a number
20 of questions were adjusted before finally sending out. Most respondents were PLAN
21 members. This should ensure familiarity with planning methods.
22
23
24
25
26

27 The industry and size of the respondents closely matched the demographics of Swedish
28 manufacturing firms in general (Olhager and Seldin, 2004). To increase the response rate
29 and to identify the reasons for non-responses, potential respondents received a reminder by
30 phone. Adresse(e)s were also requested to reply even if they did not intend to complete the
31 questionnaire. Four main reasons were given for not answering the questionnaire, with a
32 total of 111 non-reasons. Fifty-four (49%) stated that their company had no production or
33 inventories and was therefore not relevant for the study; 27 (24%) did not have sufficient
34 knowledge to answer accurately; 23 (21%) did not have enough time or did not wish to
35 answer the questionnaire; and 7 (6%) no longer worked for the company. The population of
36 manufacturing companies could thus be adjusted to 533, which gives an adjusted response
37 rate of 29%. If 49% of all companies were irrelevant for study, then the response rate would
38 be 55%. The responding adjusted distribution company population is 455 and the adjusted
39 response rates 12% and 22% respectively. Chi-square tests did not reveal any significant
40
41
42
43
44
45

1
2
3 difference between respondents and non-respondents regarding company size or industry in
4
5 any of the surveys. It should therefore be possible to generalise the findings for most
6
7 manufacturing industries.
8
9

10 A four-page file with definitions and descriptions of the methods for material planning
11 was attached to the surveys. The aim was to ensure that the measures were valid and that
12
13 the respondents had the same definitions of planning methods, which further improved the
14
15 understanding and validity of the study.
16
17
18

19
20 The criterion-related (predictive) validity of the subjective measure of perceived
21 performance was tested by assessing the relationship between scores on the predictor scale
22
23 and measures of the perceived overall inventory turnover rate in relation to the competitors
24
25 in the industry (measured on a 7 point scale ranging from much lower to much higher) and
26
27 the perceived overall delivery service performance to customer in relation to the
28
29 competitors in the industry (measured on a 7 point scale ranging from much worse to much
30
31 better). Table 3 shows the bivariate correlations between the measures. For MRP there are
32
33 significant correlations between the perceived operational performance and both the
34
35 inventory turnover rate and delivery service. The correlation between the perceived user
36
37 friendliness and the delivery service is also significant. For the re-order point method there
38
39 are significant correlation between both the perceived operational performance and user
40
41 friendliness and the inventory turnover rate. However, the correlations with the delivery
42
43 service are not significant. The correlations with the inventory turnover rate are expected to
44
45 be higher than with the delivery service because the methods directly affects the inventory
46
47 levels but only indirectly the delivery service. For the fixed order interval, run-out time
48
49 planning and kanban methods the only significant correlation existed between the
50
51
52
53
54
55
56
57
58
59
60

operational performance and delivery service for kanban. The levels of significance are lower for these methods, mainly because of lower number of respondents. The correlations between the perceived operational performance and perceived user friendliness are significant ($p < 0.01$) for all methods. This is inline with the expectations that the user friendliness is positively affected by the operational performance. The correlation coefficient for the correlation between the two overall measures (inventory turnover rate and delivery service) was 0.154, which was significant on the $p < 0.05$ level. These tests validate the appropriateness of using the perceived operational performance as a performance measure, especially for the MRP and re-order point methods.

Insert Table 3 here

3.4 Statistical Tests

The level of measurement of the questions differed between nominal, ordinal and interval scales. Therefore, various statistical methods were applied to analyse the data. The selection of the methods followed the guidelines of for example Siegel and Castellan (1988) and Hair et al. (1998). For scales of nominal and ordinal type, statistical analysis was carried out using chi-square tests for goodness of fit. For scales of interval type, ANOVA tests were used.

4. FINDINGS

The analysis is conducted in two stages, according to the stated objectives. First, we study the use of methods to control the material flow in manufacturing companies' inventories of purchased and manufactured items and distribution operations' inventories and compare the perceived planning performance in different inventory types. Second, we compare the modes of application of the methods between firms with low and high perceived planning performance. Here, statistical significance tests are only conducted for the MRP and re-order point methods, because too few respondents using the other methods, as discussed in the methodology chapter.

4.1 Material Planning Methods in Different Inventory Types and Company Sizes

Table 4 shows the use of the five studied material planning methods to control the material flow to inventories of purchased and manufactured items in manufacturing companies and inventories in distribution companies. Re-order point and MRP methods are the significantly most common methods of controlling the material flow of purchased items. MRP is significantly most common in inventories of manufactured items compared to all other methods, and re-order point methods is significantly more common in inventories in distribution operations compared to all other methods. At first sight, it may be somewhat surprising that MRP is used in distribution operations because the method is not designed for controlling independent demand items. However, those saying they use MRP in distribution operations may use time-phased order point or distribution requirements planning, two variants of MRP. Kanban and run-out time planning are used in all inventory types, while the fixed order interval method is not used to any great extent in manufacturing

1
2
3 companies. A reason for using re-order point related methods for controlling inventories of
4
5 purchased items can be explained by the fact that there is a great extent of low value items
6
7
8 and companies choose to control them with simpler replenishment methods than MRP.

56
57
58
59
60

Insert Tables 6 and 7 here

We also analysed the usage and general planning performance of each inventory management method in companies of various sizes and for companies in general, without considering inventory types or company sizes. When comparing companies of various sizes the significant difference with highest p-value existed for the general use of the fixed order interval method with higher usage among small and medium sized companies and for main method usage of the re-order point method with more users among small and medium sized companies. The different usage of MRP between small/medium sized and large sized companies was significant on the $p < 0.11$ level with higher usage among large companies (Table 8). This is expected, since the method to a larger extent relies on ERP support compared to the other methods. The perceived planning performance did not, for any method, differ significantly between companies of various sizes (Table 9). The only significant difference in general user friendliness, i.e. without considering inventory type or company size, existed between kanban and the period review method. For both MRP and kanban the general operational performance was significantly higher compared to the re-order point and fixed order interval methods. Thus, the previous two methods were considered to be more user friendly, no matter inventory type were they are used or company size.

4.2 Parameter Determination and Method Usage

Table 10 shows a comparison between companies with perceived high and low performance of the respective method, measured in terms of user friendliness and operational performance. The two performance variables discussed in the methodology chapter and in the previous section were used. Respondents marking “1”, “2” or “3” on the 7-point scales were defined as “low performance”; and firms and respondents marking “5”, “6” or “7” were defined as “high performance” firms. The modes of application defined in Table 2 were compared between the low and high performance firms using chi-square tests.

Insert Table 10 here

A few statistically significant differences between firms with low and high perceived planning performance were identified for the re-order point and MRP methods.

For the re-order point methods, the degree of analytical order point determination (i.e. calculating the order point as the sum of the demand during lead time plus safety stock rather than using experience) and the frequency of order point revision differed

1
2
3 significantly between users with different perceived operational planning performance.
4
5 Firms generating future demand data through MRP or monthly forecast calculations also
6
7 showed significantly (at the $p < 0.10$ level) higher operational performance compared to
8
9 those who used experience or simply the previous year's demand. Furthermore, many order
10
11 changes before release were associated with significantly lower operational performance.
12
13 The only significantly characteristic mode of application among re-order point users who
14
15 find the methods user friendly is that they need to deal with fewer changes of planned
16
17 orders before release.
18
19
20
21

22 For MRP users, analytical lead-time determination, frequency of safety stock revision,
23
24 frequency of manufacturing lead-time revision and planning frequency differed most
25
26 significantly between users with various degrees of perceived operational planning
27
28 performance. MRP supported by an ERP system that generates re-planning suggestions is
29
30 considered significantly more user friendly than systems without re-planning support in the
31
32 ERP. Firms with higher frequencies of safety stock revision, purchasing lead-time revision
33
34 and lower numbers of order changes before order release also found the method more user
35
36 friendly compared to those that did not.
37
38
39
40

41 The findings confirm the expectations that analytical modes of determining parameters
42
43 and higher review frequencies have positive impacts on planning performance. However,
44
45 the relationships were only verified for some critical variables (determination and revision
46
47 of order points for re-order point methods and lead-time determination and revision and
48
49 safety stock revision for MRP) and not for the overall indexes, except for the review
50
51 frequency index for the operational re-order point performance and user friendliness of
52
53 MRP. The relationships were also only valid for the impact on the perceived operational
54
55
56
57
58
59
60

1
2
3 performance of the methods and not for their perceived user friendliness. It can, though, be
4 expected that the perceived user friendliness depends more on the user friendliness of
5 available ERP systems than on the method used. The assumption about the planning
6 frequency was verified for MRP regarding its impact on operational performance. The
7 assumption about order modification was verified for both methods and performance
8 measures, except for the operational performance of MRP. The assumption regarding
9 automatic re-planning was verified for its impact on user friendliness but not for
10 operational performance.
11
12
13
14
15
16
17
18
19
20
21

22 The reasons for high or low perceived planning performance among the fixed-order
23 interval and run-out time planning users follow the same pattern as for MRP and re-order
24 point users. Analytical determination of run-out time, order intervals and safety stocks
25 seems to be important, as well as, frequent safety stock determination and few order
26 changes before release. It is hard to draw and conclusions of the reasons for high or low
27 kanban performance. One possible tendency is, though, that users that only need one
28 kanban to start production show higher planning performance compared to those that need
29 several kanbans. This verifies the need for small set-up times and batch sizes in order to
30 successfully apply the kanban method. However, the findings related to the fixed-order
31 interval, run-out time and kanban methods are not based on statistical significance tests but
32 are rather visual analyses of the figures in Table 11.

5. DISCUSSION

The study showed that MRP is the most used and ROP the second most used method for controlling material flows to inventories in manufacturing companies. In distribution operations, however, ROP and ROP-related methods (fixed order interval method, run-out time planning and kanban) are the most commonly used main methods. The findings do not verify the conclusions of Rabinovich and Evers (2002) that MRP related methods was also the most important method for controlling finished goods inventories, for example stocks in distribution operations.

MRP and kanban are perceived to result in better general performance compared to re-order point and fixed order interval methods. This is interesting as MRP is more dependent on the quality of the planning information and the ERP support than the other methods.

The most important application modes for achieving high operational planning performance among re-order point users were to determine the order point as the demand during the lead time plus a safety stock, and to frequently review this order point quantity. By doing so the method becomes more dynamic, i.e. responsive to demand and lead-time fluctuations. The method works best in a stable environment where the demand is smooth and lead times are short and fixed. However, several companies use the method in other environments and therefore require a more dynamic method in order to achieve a satisfactory planning performance. A corresponding indirect effect could be achieved by deriving the demand data from a requirements calculation or monthly forecasts instead of using the previous year's sales figures or an annual estimate. This performance impact was also identified in the study. It shows the importance of combining several methods in an

1
2
3 integrated planning approach, and the possibility of using MRP as a complement to re-order
4
5 point methods.
6
7

8 The study showed that accurate lead times and safety stocks are two of the most critical
9
10 parameters for achieving high MRP performance. To achieve high accuracy, lead times
11
12 must be periodically reviewed to reflect the current situation faithfully. This is an issue of
13
14 balancing the cost of reviewing and the benefits of more accurate lead times.
15
16 Manufacturing lead times could be calculated automatically from filed data in the ERP
17
18 system or based on real-time logging of operation times. The same is true for safety stocks,
19
20 which should be properly determined and frequently reviewed to allow for dynamic and
21
22 efficient material planning. The identified importance of safety stock determination is
23
24 interesting, because studies show that only a minority of companies use analytical safety
25
26 stock approaches (e.g. Sandvig, 1998, Jonsson and Mattsson, 2006). Companies with a
27
28 daily MRP planning frequency also showed significantly higher planning performance
29
30 compared to those with weekly planning. The argument is the same as for more analytical
31
32 determination and frequent revision, as it results in a more dynamic method. It is also in
33
34 line with current practice. Jonsson and Mattsson (2006) showed that the majority of MRP
35
36 users changed from weekly to daily planning frequencies between 1993 and 1999 and that
37
38 daily planning now is the dominating planning frequency for all methods.
39
40
41
42
43
44

45 The findings further indicate that sufficient operational performance equates to a user
46
47 friendly method. If the method results in high operational performance, for example as a
48
49 result of analytically determined and frequently revised parameters, users are more likely to
50
51 find the method user friendly. However, other issues affect the perceived user friendliness,
52
53 for example, the characteristics of the ERP system that supports the planning process. For
54
55
56
57
58
59
60

1
2
3 MRP, the user friendliness is also higher with an ERP system with automatic re-planning
4
5 support, i.e. if the system is allowed to take more active control of the planning process.
6
7

8 The study shows that order quantity determination and revision have no impact at all on
9
10 planning performance. Rather, the re-order point (or the replenishment level, run-out time,
11
12 number of kanbans, respectively) is significantly the most important parameter to determine
13
14 and review in re-order point methods and safety stock and lead times in MRP. This finding
15
16 is interesting because order quantity related studies still receive greater emphasis in
17
18 research.
19
20

21
22 Guiding managerial implications of the study are summarised in Table 11. Issues to
23
24 consider and guidelines to follow are related to the three phases of designing and using
25
26 material planning methods; 1) matching method and planning environment, 2) designing
27
28 material planning method and 3) using material planning method.
29
30

43 **6. CONCLUSIONS**

44
45 The study concludes that the use of material planning methods differs depending on where
46
47 along the material flow they are applied, whether the inventory is located in a
48
49 manufacturing company or in distribution operations and between companies of various
50
51 sizes. The modes of applying a material planning method affect its perceived performance.
52
53 In particular, the way of determining and the review frequency of safety stocks and lead
54
55 times have great importance for the planning performance of MRP methods, while the
56
57
58
59
60

1
2
3 determination and review of order points, review frequencies and run-out times were
4
5 important for re-order point methods.
6
7

8 The present study has focused on the operational strategies for determining and
9
10 reviewing planning parameters and the planning frequencies of material planning methods.
11
12 The conclusions clearly indicate the importance of how the material planning methods are
13
14 applied, and in particular how the planning parameters are determined and reviewed, in
15
16 order to successfully manage material planning.
17
18

19
20 In every planning and control situation there are different planning conditions that
21
22 impact the possibility of favourable application modes, but which may also have a direct
23
24 impact on planning performance. Such conditions include, for example, the method support
25
26 in the ERP system, the educational and knowledge level of the material planning method,
27
28 management commitment, the organisational design and functioning of planning and
29
30 control, the available time for planning and control, the inventory accuracy and the lead-
31
32 time precision in the ERP system. To further understand how to successfully employ
33
34 material planning methods, it would thus be valuable to study the impact of planning
35
36 conditions on operational strategies and their direct effect on planning performance.
37
38

39
40 There is a need for more focused studies on specific methods. Here, significant test
41
42 could only be conducted for the MRP and re-order point methods. There is also a need for
43
44 more focused studies on different planning environments in order to better understand the
45
46 contextual impact on planning performance, for example, including the user environment
47
48 (knowledge, management support, planning organisation, software support, lead time
49
50 precision, etc.). A minority of the respondents represents distribution operations and the
51
52 response rate was quite low for distributing companies. Most studies on material planning
53
54
55
56
57
58
59
60

1
2
3 focuses on manufacturing operations. Therefore, it would be interesting with future studies
4
5 focusing on material planning in distribution operations. In this study, subjective measures
6
7 of the planning performance were used. Further development of instruments for measuring
8
9 the direct and indirect planning performance are needed.

Table 1 Characteristics of respondents

Table 2. Modes of application variables and measures

Table 3. Correlation between perceived planning performance and ITR/delivery service

Table 4. Number and percentages of method users

Table 5. Number and percentages of main method users

Table 6. Perceived user friendliness for the respective inventory management policy

Table 7. Perceived operational performance for the respective inventory management policy

Table 8. Number and percentages of method and main method users with different company sizes

Table 9. Perceived user friendliness and operational performance in general and in different company sizes

Table 10 Modes of application among companies with perceived low and high performance of main methods

Table 11. Managerial issues and guidelines related to planning phases

Table 1. Characteristics of respondents

	Manufacturing companies		Distribution operations	
	Number of responses	Percentage	Number of responses	Percentage
Size:				
Small & Medium sized	45	30%	22	45%
Large sized	103	70%	27	55%
		100%		100%

Note: Chi-square 3.44 (sign $p < 0.07$)

Table 2. Modes of application variables and measures

Method	Variable	Measure
Re-order point methods	1. Analytical order quantity determination	1) Experience based fixed quantity or number of periods covered; 2) Economic order quantity
	2. Analytical safety stock determination	1) Safety-stocks included in the re-order point or based on judgment and experience, 2) Adding a percentage on the lead time requirement or calculated from a specified service level
	3. Analytical order point (replenishment level) determination	1) Based on experience and judgment, 2) Calculated as lead-time demand plus safety stock
	4. Ways of estimating demand	1) Experience or last year's demand, 2) forecasting or MRP
	5. Analytic determination index	(Variable 1+Variable 2+Variable 3+Variable 4)/4 → If 1-1.25 then code 1 (i.e. low overall analytical strategy); If 1.75-2.00 then code 2 (i.e. high overall analytical strategy).
	6. Frequency of order quantity revision	1) Annually or less frequent, 2) At least a couple of times per year
	7. Frequency of order point revision	1) Annually or less frequent, 2) At least a couple of times per year
	8. Review frequency index	(Variable 6+Variable 7)/2 → If 1 then code 1 (i.e. low overall frequency); If 2 then code 2 (high overall frequency).
	9. Planning frequency	1) Once a week or less frequent, 2) Daily or more frequent
	10. Order changes before release	1) Very few, 2) A rather large amount
Fixed order-interval method	1. Analytical determination of the replenishment level	1) Based on experience and judgment, 2) Calculated as demand during lead-time and review period plus safety stock
	2. Analytical safety stock determination	1) Safety-stocks included in the replenishment level or based on judgment and experience, 2) Adding a percentage on the lead time requirement or calculated from a specified service level
	3. Analytical determination of review period	1) Based on experience and judgment, 2) calculated as the economic order quantity
	4. Analytical ways of estimating demand	1) Experience or last year's demand, 2) forecasting or MRP
	5. Frequency of replenishment level revision	1) Annually or less frequently, 2) At least a couple of times per year
	6. Frequency of review period revision	1) Annually or less frequently, 2) At least a couple of times per year
	7. Order changes before release	1) Very few, 2) A rather large amount
Run-out time planning	1. Analytical determination of the run-out time	1) Available inventory divided by last years demand or available inventory divided by forecasted demand, 2) Available inventory divided by MRP generated future demand or period by period calculation when the inventory

		is zero.
	2. Analytical safety stock determination	1) Safety-stocks/safety time determined intuitively, 2) Adding a percentage on the lead time requirement or calculated from a specified service level
	3. Analytical order quantity determination	1) Experience based fixed quantity or number of periods covered, 2) Economic order quantity
	4. Use of priority numbers	1) No, 2) Yes, the run-out time in relation to the lead time
	5. Frequency of safety stock revision	1) Annually or less frequent, 2) At least a couple of times per year
	6. Frequency of order quantity revision	1) Annually or less frequent, 2) At least a couple of times per year
	7. Planning frequency	1) Once a week or less frequent, 2) Daily or more frequent
	8. Order changes before release	1) Very few, 2) A rather large amount
Kanban	1. Electronic kanban type (manufacturing)	1) One or two card kanban, 2) Electronic kanban (e-mail, etc.)
	2. Analytical card determination	1) Based on judgment and experience, 2) Based on calculations
	3. Electronic kanban type (suppliers)	1) Communication with carrier, mail or fax ¹ , 2) Communication with EDI or e-mail
	4. Number of cards to start production	1) For at least some items more than one card, 2) One card
	5. Inventory account	1) No item reservation, 2) Item reservation
MRP	1. Analytical order quantity determination	1) Experience based quantity or time period, 2) EOQ, dynamic optimization or lot-for-lot
	2. Analytical lead time determination	1) Based on general judgment and experience, 2) Based on calculations in the ERP system or on monitored actual lead times
	3. Analytical determination index	$(\text{Variable 1} + \text{Variable 2})/2 \rightarrow$ If 1 then code 1 (i.e. low overall analytical strategy); If 2 then code 2 (i.e. high overall analytical strategy).
	4. Frequency of order quantity revision	1) Annually or less frequent, 2) Reviews a couple of times a year or more frequent
	5. Frequency of safety stock revision	1) Annually or less frequent, 2) At least a couple of times per year
	6. Frequency of manufacturing lead time revision	1) Annually or less frequent, 2) Reviews a couple of times a year or more frequent
	7. Frequency of purchasing lead time revision	1) Annually or less frequent, 2) Reviews a couple of times a year or more frequent
	8. Review frequency index	$(\text{Variable 4} + \text{Review 5} + \text{Review 6} + \text{Review 7})/4 \rightarrow$ If 1-1.25 the code 1 (i.e. low overall frequency); If 1.75-2.00 then code 2 (i.e. high overall frequency)
	9. Planning frequency	1) Once a week or less frequent; 2) Daily or more frequent

Automatic replanning	11 (57%)	46 (84%)	5.29**	15 (83%)	48 (72%)	1.01
Kanban:						
Electronic kanban type (manufacturing)	1 (33%)	3 (38%)	NA	1 (50%)	3 (33%)	NA
Analytical card determination	2 (33%)	8 (89%)	NA	2 (100%)	7 (88%)	NA
Electronic kanban type (suppliers)	1 (33%)	3 (60%)	NA	1 (50%)	2 (50%)	NA
Only one card to start production	0 (of 1)	4 (57%)	NA	0 (of 1)	3 (43%)	NA
Item reservation conducted	2 (67%)	6 (100%)	NA	1 (50%)	5 (100%)	NA

Note: A "low performance" firm has a perceived degree of performance of "5", "6" or "7", while a "low performance" firm has a perceived degree of performance of "1", "2" or "3", Figures in the table illustrate the number (and percentage of total) of respondents with answer alternative 2 in table 2, i.e. the alternatives defined as the analytical strategy and high frequency. * Statistically significant at the $p < 0.10$ level; ** Statistically significant at the $p < 0.05$ level; *** Statistically significant at the $p < 0.01$ level

Table 11. Managerial issues and guidelines related to planning phases

Phase	Issue	Guideline
1. Matching method and planning environment	Inventory types	<ul style="list-style-type: none"> • Re-order point methods are appropriate methods for control of material flows in distribution operations inventories (finished products and spare parts). • MRP is the main method for controlling inventories of manufactured semi-finished items with dependent demand and for purchased items but re-order point and especially kanban methods could perform well if used for items with appropriate characteristics. • MRP and kanban have higher general planning performance for controlling inventories of semi-finished goods compared to re-order point and fixed order interval methods.
2. Designing material planning methods	Critical parameters	<ul style="list-style-type: none"> • For re-order point methods the determination of re-order points and safety stocks are critical for achieving high perceived planning performance • For MRP the determination of lead times and safety stocks are critical for achieving high perceived planning performance
3. Using material planning methods	Critical strategies	<ul style="list-style-type: none"> • High review frequency of the critical parameters is important for achieving high perceived planning performance. • For MRP high planning frequency is also important for achieving high perceived planning performance. • It is important to fine tune the planning system so that only a minority of the order suggestions need to be modified before release and that no “unnecessary” modification is done.
