10 **Abstract**
11

12 Modern biotechnology will have a large impact on society and requires informed
13 decision-making and critical attitudes toward biotechnology among the public. This study
14 aims to explore these attitudes in secondary education.
15
16
17

18
19 For this purpose, a questionnaire was constructed according to the general tripartite
20 theory of attitudes. 574 Dutch secondary school students completed the questionnaire.
21
22 Based on principal component analyses, several distinct and independent cognitive,
23 affective, and behavioural factors were found, demonstrating that attitudes towards
24 biotechnology are a multi-component concept. In a cluster analysis on these factors, we
25 found four interpretable clusters representing different groups of students. The four
26 groups are labelled as 'confident supporter' (22%), 'not sure' (42%), 'concerned sceptic'
27 (18%) and 'not for me' (17%). These results indicate that there is a diverse appraisal of
28 modern biotechnology amongst secondary school students. Suggestions for educational
29 interventions are made.

Introduction

Genomics, the new term for large-scale scientific research on heredity and genes, and its associated technologies (modern biotechnology¹) are set to become one of the most important scientific and technological revolutions of the 21st century (Kirkpatrick, Orvis, & Pittendrigh, 2002). As such, it is important that the general public understands the main concepts of modern biotechnology. People will need such knowledge in their careers and in their daily lives as members of society to make personal and social choices about issues related to science and technology. In short, it is important that the public becomes more scientific literate in this respect. Our starting point is that science education occupies a central role in the promotion of scientific literacy (Bingle & Gaskell, 1994; Driver, Leach, Millar, & Scott, 1996; Zeidler & Keefer, 2003; Sadler & Zeidler, 2004). When developing an educational strategy, or programme, obviously one must know its 'audience' and consider what understanding modern biotechnology means, and how students arrive at personal and social choices. What kind of arguments do students use in relation to knowledge they may or may not have on the subject? In other words, what different attitudes towards modern biotechnology can be distinguished? In the next section, we will describe the results of published literature on attitudes of school students towards modern biotechnology within the last 10 years.

Former research

A small number of studies have examined understanding of secondary school students of, and attitudes towards, modern biotechnology (Dawson & Schibeci, 2003b). These studies

¹ Biotechnology is a term used to encompass a vast range of techniques for modifying life forms for research (e.g., medical, environmental, agricultural) and commercial uses.

1
2
3 have investigated students' attitudes towards school science in general (see the review of
4 (Osborne, Simon, & Collins, 2003) or attitudes towards selected biotechnological
5
6 applications such as genetic engineering of plants (Gunter, Kinderlerer, & Beyleveld,
7
8 1998) or attitudes of students towards using genetically engineered animals in medical
9
10 research (Hill, Stannistreet, O'Sullivan, & Boyes, 1999). However, most of these studies
11
12 focused on student's knowledge and understanding of biotechnology more than on their
13
14 attitudes.
15
16
17
18

19
20 The number of studies on attitudes towards biotechnology among the general public
21
22 seems quite substantial, although many of these draw from the so-called Eurobarometer.
23
24 This concerns one of the main sources of information on attitudes towards biotechnology
25
26 (European Commission, 2006). It is an extensive survey on society, science and
27
28 technology in European countries conducted several times in the past decade. The
29
30 Eurobarometer includes a number of questions on content knowledge and views among
31
32 the public regarding different applications of biotechnology. Other studies generally
33
34 focused on one specific application of biotechnology such as genetically modified foods
35
36 (GM-foods)(Verdurme & Viaene, 2003) and medical applications and cloning (Balas &
37
38 Hariharan, 1998). Below, the main studies on attitude towards biotechnology conducted
39
40 in groups of adults as well as secondary school students will be described. Our review of
41
42 these studies includes a description of the results in relation to the particular
43
44 **conceptualisation** of attitude.
45
46
47
48
49

50 Pardo, Midden and Miller (2002) have described the profile of Europeans attitudes
51
52 towards biotech applications based on the results of particular questions of the
53
54 Eurobarometer of 1996. In their article, attitudes were defined as an evaluation of an
55
56
57
58
59
60

1
2
3 object based on a cognitive component (information and knowledge about the properties
4 of the object) and an evaluative component (affect and feelings of approval or
5 disapproval toward the object). Pardo et al. expected the public to hold general views on
6 the one hand, as well as more differentiated views regarding specific biotech applications
7 on the other. This means that attitudes towards biotechnology are expected to be
8 fragmentary, especially because it concerns such a complex and developing subject. The
9 Eurobarometer included questions about six specific applications of biotechnology (in the
10 medical as well as food production area), and examined to what extent the respondents
11 finds these applications useful, risky, moral acceptable, and whether or not the person
12 would encourage each of the applications. First of all, the results showed that, while some
13 progress in terms of basic scientific knowledge have been made since the Eurobarometer
14 of 1996, the knowledge - and information gap between science and society still exists.
15 Furthermore, attitudes (comprising the perception of usefulness, risk, moral acceptability
16 and encouragement) were somewhat more positive when medical applications are at stake
17 (research and transplants), compared to foods and agricultural applications.
18 Pardo et al. continued their article by conducting a structural analysis that aimed to
19 explain the perceived benefits and risks. A positive perception of the benefits was
20 predicted by a general technological optimism, a belief in the promise of biotech and
21 being part of an informed public (groups were divided based on a knowledge test, p. 11,
22 note 2). The same model, however, failed to predict the perception of risk, suggesting that
23 other factors in the structural model were needed to explain underlying reasons for the
24 public to perceive biotechnology as a risk.

1
2
3 Dawson and Schibeci (2003a) have conducted a study among 1116 secondary school
4
5 students from different Western Australian schools on the understanding of recent
6
7 advances in modern biotechnology. For this research, a written survey was used to
8
9 determine their understanding of, and attitudes towards, recent advances in modern
10
11 biotechnology, such as genetic engineering, cloning and GM-foods.
12
13

14
15 In this study, attitudes were defined in terms of acceptability of biotechnological
16
17 procedures. Students indicated **whether** they thought different procedures were acceptable
18
19 and clarified their choice. The survey included six questions related to understanding and
20
21 acceptance of biotechnological applications and procedures.
22
23

24
25 Approximately one third of the students turned out to have little or no understanding of
26
27 biotechnology and one third was unable to give a single example of biotechnology.
28

29
30 However, there was considerable variation in the understanding of students.

31
32 The results on attitude towards biotechnology in a successive study (Dawson & Schibeci,
33
34 2003b) showed that the students hold a wide range of beliefs about what is an acceptable
35
36 use of biotechnology. The students' responses divided approximately into four groups
37
38 depending on whether they approved of the use of **micro-organisms** only, **micro-**
39
40 **organisms** and plants, **micro-organisms**, plants and animals, or all living organisms.
41
42

43
44 Acceptance of the use of organisms in biotechnology decreases from micro-organisms
45
46 (>90% approval) to plants (71 - 82%) to humans (42 - 45%) and animals (34 - 40%).
47

48
49 Clarification of their statements for acceptance or rejection was rather negative.

50
51 Arguments such as 'the procedure is wrong', 'unnatural', or 'unethical' were given.

52
53 Reasons for acceptance were that procedures will benefit humanity or 'if it can be done
54
55 then it should be done'.
56
57
58
59
60

1
2
3 Gunter et al. examined the understanding and opinion towards biotechnology of 48
4 teenagers, with special reference to food production. This study was part of a large
5 project designed to investigate public awareness and perception of biotechnology. The
6 results showed that despite these young peoples' poor understanding of biological
7 sciences, they seemed less reluctant towards GM-foods than did adult-respondents.
8 Overall, teenagers considered genetic engineering of plants to be more acceptable than
9 genetic engineering of food crops and animals. Their reasons for opposing genetic
10 engineering of animals was that it is 'unnatural', 'dangerous', 'shouldn't be done' and
11 'unethical'.
12
13

14
15 Similar reasons were reported by Hill et al. (1999) who examined the attitudes of 778
16 students aged 11 - 18 years about using genetically engineered animals in medical
17 research. 42% of the sample felt it should not be allowed, because it was cruel (47%), or
18 unnatural (53%).
19
20

21
22 Hill et al. also found that biology students were less likely to be neutral and more likely
23 to be positive about genetically engineered foods than other students. While these
24 positive attitudes may be the result of a greater understanding of biotechnology, it could
25 also be argued that the students who have chosen to study biology have a more positive
26 attitude to science than other students.
27
28

29
30 From the angle of non-persuasive communication, Verdurne and Viaene (2003)
31 conducted a study on consumer beliefs and attitudes towards GM-foods. Their attitude
32 model included risk and benefit perceptions, which were determined by general attitudes
33 and knowledge about GM-foods. In their interviews with 400 Belgian consumers, they
34 asked about the risk and benefits, awareness and knowledge, attitudes towards science,

57
58
59
60

1
2
3 trust in the government, and beliefs, attitudes and purchase intentions regarding GM-
4
5 foods. They observed three general factors based on the risk and benefit items: a general
6
7 health risk factor, a benefit factor and an environmental risk factor. These three factors
8
9 clustered into four consumer segments: 'the half-hearted' (34%), 'the green opponents'
10
11 (16%), 'the balancers' (27%) and 'the enthusiasts' (24%). Several items that combined
12
13 into one general scale with a high reliability, measured attitudes. Knowledge was
14
15 measured using the Eurobarometer knowledge items. The results showed that higher
16
17 levels of knowledge do not necessarily imply greater acceptance of GM-foods.
18
19
20 In summary, looking at these studies suggests that attitudes towards biotechnology do not
21
22 yet constitute a coherent research area. Some studies defined attitudes in terms of benefits
23
24 and risks, some defined attitudes in terms of acceptability, and others in terms of a
25
26 general evaluation. Most studies described a link between understanding or content
27
28 knowledge and attitudes, but few studies actually investigated this link. Pardo and Calvo
29
30 (2002) criticised the theoretical underpinning of attitudes towards science (and
31
32 biotechnology) as measured in the Eurobarometer. They stated that little to no attention
33
34 was paid to the content of attitudinal items and argued that this leads to conceptual and
35
36 metrical weakness of scales. The consequence is that empirical support for some
37
38 published results is very limited (see for an in-depth discussion; (Miller, 1998; Pardo &
39
40 Calvo, 2002, 2004). This seems to be a recurrent issue with research on attitudes. It is not
41
42 only a complex construct, but a person's attitude seems also incomplete and in a state of
43
44 evolution, especially in case of extremely complex subjects such as biotechnology
45
46 (Campbell, Converse, Miller, & Stokes, 1976; Pardo, Midden, & Miller, 2002).

1
2
3 The present study uses the theoretical tripartite model of attitudes (Katz & Stotland,
4
5 1959; Rosenberg & Hovland, 1960) as a starting point. This model encompasses three
6
7 basic attitude components: an affective, a cognitive, and a behavioural component. By
8
9 choosing this theoretical and empirical strongly underpinned conceptualisation of
10
11 attitudes, we intend to accommodate the critique of Pardo regarding the generally weak
12
13 conceptualisation of attitudes towards science. Furthermore, each of the three
14
15 components is considered as a multi-dimensional component: our conceptualisation of
16
17 attitudes attempts to uncover different sets of affective, cognitive and behavioural
18
19 reactions towards modern biotechnology. By doing this, the present study contributes to
20
21 research on attitudes towards modern biotechnology by exploring the concept of attitudes
22
23 in detail.
24
25
26
27
28
29
30
31

32 *The attitude model in the present study*

33
34 In general, an attitude can be described as a summary evaluation depicting favourable or
35
36 unfavourable feelings towards a specific or psychological object (Eagly & Chaiken,
37
38 1993; Weinburgh & Engelhard, 1994; Ajzen & Fishbein, 2000; Zacharia, 2003). In the
39
40 present study the object is modern biotechnology, in specific the associated technologies
41
42 of genomics. According to the tripartite theory of attitudes, attitudinal responses can be
43
44 classified into three general components; an affective, a cognitive, and a behavioural
45
46 component (Katz & Stotland, 1959; Rosenberg & Hovland, 1960; Breckler, 1984; Eagly
47
48 & Chaiken, 1993). The cognitive as well as the affective component influence
49
50 evaluations which in turn affects behavioural intentions (Tesser & Shaffer, 1990; Heijs,
51
52 Midden, & Drabbe, 1993; Ajzen, 2001). In the cognitive component, the evaluation of
53
54
55
56
57
58
59
60

1
2
3 modern biotechnology follows from beliefs, thoughts and knowledge of the object. The
4
5 affective component of attitudes reflects how students feel about genomics, for instance
6
7 anxieties and fears about this contemporary technology. Furthermore, attitude is one of
8
9 the important determinants of intentions and behaviour, for example consumption or
10
11 protest (theory of planned behaviour) (Ajzen & Fishbein, 2000; Armitage & Conner,
12
13 2001; Zacharia, 2003).
14
15
16
17
18
19

20 *Research questions*

21
22 The concept of attitude includes levels of knowledge as well as cognitive and affective
23
24 evaluations and behavioural intentions. In the following quantitative study, each of the
25
26 components of the tripartite attitude model will be explored and related to each other.
27
28

29 **Therefore**, the following three research questions can be formulated:
30
31

- 32 1. Which kind of cognitive, affective evaluations and behavioural intentions can be
33 observed?
34
35
- 36 2. How do these attitude components interrelate?
37
38
- 39 3. Can different attitude patterns of secondary school students be distinguished?
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

Method

The main aim of this study is the exploration of secondary school students' attitudes towards modern biotechnology in more detail. For this purpose an instrument (questionnaire) was designed which measures the various attitude components in relation to content knowledge and different areas of modern biotechnology.

Participants

Based on a list of all Dutch schools in four large cities in the western part of the Netherlands, teachers were invited to participate with their students. A total of 47 schools were approached, of which thirteen consented to participate with one or more of their classes of sixteen-year-old students.

In the Netherlands, the secondary education system for pupils aged between twelve and eighteen years is divided into three main levels: secondary vocational education (VMBO, 12-16 years), general secondary education (HAVO, 12-17 years), and pre-university secondary education (VWO, 12-18 years). A total sample of 634 secondary school students of all three main school levels took part in the study.

Students were excluded from subsequent analysis if they completed less than 33.3% of the questionnaire or showed a 'suspicious' answer-pattern, e.g., all questions were responded to in identical fashion, or included contradictions. This resulted in a dataset of 574 respondents, 147 from VMBO² (25.6%), 147 from HAVO (25.6%), 280 from VWO (48.8%), with 262 males (45.6%) and 312 females (54.4%). Focus was on sixteen-year-old students (mean = 15.8 year, SD = 0.66).

² The group of students in the pre-vocational tracks are underrepresented (in Dutch educational system nearly 60% of secondary school students are in this track), and also the coverage of the region is not equally spread.

Design of instrument

The questionnaire was designed based on two sources: a variety of existing surveys and a small-scale qualitative research study.

A literature search regarding possible surveys resulted in a number of instruments of which items could be used for the purpose of the present study, including surveys on attitude towards science. The most important of these are the Eurobarometer (European Commission, 2001), the instrument of Heijs (Heijs et al., 1993) and the International Bioethics Survey Questionnaire. One or more items or ideas have been taken from other surveys³.

The qualitative study consisted of six group discussions with four different sixteen-year-old students (from all three main educational levels) and thirteen in-depth interviews with researchers in the field of genomics.

In the group discussions, the students were questioned about their knowledge and understanding of biology, genetics and modern biotechnology, their feelings towards several applications of biotechnology, and behavioural intentions towards biotechnology.

The students were also asked to elaborate their perception of risk associated with biotechnology, their ethics and beliefs, and their own experience and interest.

Discussions with the students were tape-recorded and the responses were transcribed verbatim and analysed afterwards. Each interview lasted approximately fifty minutes.

The qualitative study among students served two goals. First of all, the open-ended questions uncovered the cognitive and affective base of attitude in detail. This is an important condition to arrive at construct validity of the instrument.

³ (Human Genetics Commission, 2000; Centre for Consumer & Biotechnology, 2002; Princeton Survey Research Associates, 2002).

1
2
3 Secondly, the interviews with students were also used to adapt the used language in the
4 existing instruments. This adaptation was needed because these instruments generally aim
5
6
7
8 at adults.
9

10 The interviews with genomics researchers resulted in an overview of modern
11
12 biotechnology. In accordance with existing **instruments**, the objects have been classified
13
14 as follows: agriculture (plants, food industry), livestock (animals, animal experiments,
15
16 food industry), medical science (medicines, diagnostics, treatments), industry (micro-
17
18 organisms) and legislation.
19
20
21
22
23

24 *The instrument*

25
26
27 The first section of the instrument was designed to obtain (socio-) demographic
28
29 information about the students. The second and third part of the instruments includes four
30
31 categories of items: knowledge items, cognitive evaluation items (beliefs), affective
32
33 evaluation items, and behavioural intention items.
34
35
36
37
38

39 *Knowledge items*

40
41 In the second section, the cognitive component of attitude towards biotechnology was
42
43 measured through 47 true-false items (bivariate items). In this instrument, the items cover
44
45 relevant school-subjects in the field of biotechnology: 'biology and genetics' and
46
47 'technology and science'. Students should (or could) have learnt about these subjects in
48
49 school or from popular science programmes or magazines. Some items cover the existing
50
51 misconceptions about modern biotechnologies. Incorrect answers on these items reflect
52
53
54
55 not only lack of scientific knowledge (textbook knowledge) but also a tendency to
56
57
58
59
60

1
2
3 associate biotechnology with several existing inaccuracies (European Commission,
4
5 2001).
6
7
8
9

10 *Cognitive and affective evaluation items*

11
12 The third section asked students about their cognitive and affective evaluation about
13 biotechnology. The affective evaluation is measured by 28 Likert-type items, represented
14
15 by questions concerning negative and positive feelings and emotions towards different
16
17 aspects of modern biotechnology. Thirteen items on cognitive evaluation tried to capture
18
19 beliefs, expectancies, and perceptions of modern biotechnology.
20
21
22
23
24
25
26

27 *Behavioural intention items*

28
29 The third section also measured the behavioural intentions (20 Likert-type items). Since
30
31 secondary school students usually have not encountered many contexts in which they had
32
33 to act or make a decision regarding biotech issues, we decided to measure behavioural
34
35 intentions as a proxy for actual behaviour. These intentions were examined by outlining
36
37 situations in which one will or will not act (protest against genetic modification of crop),
38
39 buy (jeans made of genetically modified cotton) or use (genetic screening).
40
41
42
43
44
45

46 The items from the third section were measured by five ordinal categories ranging from
47
48 'strongly disagree' to 'strongly agree' (Becker & Maunsaiyat, 2002). Together, the
49
50 second and third sections of the instrument measured the basic components of attitude.
51
52
53
54
55
56
57
58
59
60

Fourth section

The questionnaire continues with explanatory factors: students' ethical opinions (number of items is 45), their interest in biotech (n = 10), source of information and school factors (n = 9), benefits and risk of biotechnology (n = 35), own judgement of opinion (n = 13) and trust in biotechnology and different institutes. In a subsequent **article**, the results of these explanatory factors will be described, together with the relationships between background variables and attitude.

Administration

In the period from February through April 2004, teachers administered an on-line version of the questionnaire during a regular class. In this way, the questionnaire could be answered immediately, and the response rate of the students was 100%. Either the teacher or the researcher gave the students instructions.

Analyses

Data were analysed by means of the Statistical Package for Social Sciences software, version 12.0.1. (SPSS). The analyses were conducted in two steps: 1) scaling of attitudinal factors and 2) exploring subgroups of students sharing similar 'attitudinal values'.

In the first step of scaling, factor analyses (principal component analyses with varimax rotation) and reliability analyses are used to arrive at underlying structures of the three main components of attitude.

1
2
3 Subsequently, the items loading high on the 'interpretable' factors are analysed in
4 reliability analysis. To arrive at scales with sufficient reliability, items with low item-total
5 correlation were removed from the scale and excluded from further analysis. This was
6 done only in those instances where the content of the scale was not jeopardized.
7
8
9

10
11
12 In the second step, K-means cluster analysis using Euclidean distance was
13 performed on the attitudinal scales. K-means cluster analysis is a statistical method for
14 finding subgroups of individuals who share similar 'values' on a set of variables, builds
15 group clusters by finding cluster centres on values of variables and assigning cases to the
16 cluster that produce the best-fit model.
17
18
19
20
21
22
23

24 25 26 **Results**

27
28 **First**, we present the results of the factor analyses.
29

30 31 *Content knowledge*

32
33 The item pool consisted of 47 true-false statements intended to cover, as broadly and as
34 relevantly possible, 'school-topics' of biotechnology and genetics. The mean score for the
35 whole sample was 34.02 (SD = 5.33).
36
37
38

39
40 We constructed the scales based on a priori classification of the items (according to the
41 contents of the Dutch secondary biology education), namely 1) biology and genetics and
42 2) biotechnology and its applications.
43
44
45

46
47 Although the items loading high on the first factor resulted in a scale with a Cronbach's
48 alpha of 0.63 (borderline), it was clearly interpretable and we decided to accept it as a
49 scale (n = 9). The second factor resulted in a reliable scale with an alpha of 0.71 (n = 17)
50
51
52
53
54
55 (Table 1).
56
57
58
59
60

1
2
3 *Cognitive evaluation, beliefs.*
4

5 The questionnaire included 11 items that aimed to evaluate attributes of genomics. An
6 exploratory factor analysis was conducted on the responses to the 11-evaluation items.
7
8 Principal components analysis with varimax rotation (PCA: VR) was initially performed
9
10 without specifying the number of factors to extract, since there was no expected factor
11
12 structure. Factor analysis showed that the best result was a one-factor solution with five
13
14 items on beliefs about biotech (explained variance is 26.1%). Reliability analysis
15
16 confirmed this finding with an alpha of 0.70 (Table 1). Apparently, students group all
17
18 'cognitive' attributes on one dimension. They are either positive or negative about the
19
20 different genomics attributes.
21
22
23
24
25
26
27
28

29 *Affective evaluation*
30

31 Also on the responses to 29-affect items, an exploratory factor analysis was conducted,
32
33 without specifying the number of factors to extract. A solution with three factors (in total
34
35 27 items) turned out to be interpretable. The three factors explained 38.4% of the
36
37 variance. The first factor indicated a basic emotional reaction to biotechnology, such as
38
39 being scared or excited. The second factor indicated feelings of biotechnology as an
40
41 unavoidable process ('it is going to happen anyway'). The third factor indicated a worried
42
43 stance, or a feeling of unease regarding biotech developments.
44
45
46
47

48 A reliability analysis confirmed this finding. The items showing high factor loadings
49
50 were included in reliability analyses, which resulted in three reliable scales as shown in
51
52 Table 1.
53
54
55
56
57
58
59
60

Behavioural intentions

As mentioned before, the decision was made to incorporate questions regarding students' behavioural intentions only. A total of 20 items was included, and three factors, which explained 58.6% of variance, were extracted. The first interpretable factor ($\alpha = 0.78$) covered intentions of consuming when there is a personal benefit to gain, for instance when genetically modified (GM) products are cheaper or contain less fat. The second factor included medical intentions, such as undergoing genetic tests, and resulted in a reliable scale of $\alpha = 0.74$. The third factor also included consuming intention, but under critical or environmental conditions (e.g. environmentally friendlier). This factor resulted in a scale with a Cronbach's alpha of 0.74 (Table 1)

[Insert table 1 about here]

Clustering of students

Finally, the whole dataset was subjected to a K-means cluster analysis using Euclidean distance. In this step, we investigated whether subgroups could be identified within the whole group of students. Cluster analysis was used to examine these subgroups. Because of the exploratory nature of these analyses, different numbers of clusters were analysed. An analysis with four clusters led to interpretable and interesting groups with sufficient numbers of students. Figure 1 portrays the factor scores in each of the four clusters.

60

Confident supporter (cluster 1)

Positive, pro-biotechnology and well educated in science, the 'confident supporter' (130 students, 22.6% of the respondents) seems to welcome biotechnology in their daily lives. Not only do they hold great expectations for the future, they are enthusiastic and have no worries. They tend to be confident about their future intentions of becoming a consumer of 'biotech- products', from eating genetic modified foods to taking genetic tests during pregnancy (Figure 1).

Not Sure (cluster 2)

This group of 239 students (41.6%) forms the largest group of students. Their views tend to be quite indistinct: they are neither 'anti-biotechnology' nor 'pro-biotechnology'. The students in the 'not sure'-group have a good knowledge base and hold positive beliefs about biotechnology but are sceptical when it comes to their 'gut-feelings' (basic-emotions). There is also quite some concern about biotechnological developments. However, their negative affection, does not stop them from having intentions towards consuming biotech products, especially not if critical or environmental conditions are met. They also seem to appreciate its applications in the medical world (Figure 1).

Concerned sceptic (cluster 3)

This relatively well-informed group of 105 students (18.3%) tends to be very sceptical and concerned about biotechnology. They hold sceptical believes towards biotechnology and seem to be scared and concerned of what modern biotechnology will bring. They fear

1
2
3 the impact on nature and **do not** see it as a 'natural' evolvement of the current society.

4
5 The 'concerned sceptics' have no intention of having anything to do with it now or in the
6
7 future, especially not in the medical field (Figure 1).
8
9

10 11 12 *Not for Me (cluster 4)*

13
14
15 This group consists out of 100 students (17.4% of the total), and is thereby the smallest
16
17 group. They are very negative when it comes to biotechnology. They hold very little
18
19 knowledge about the subject, and their beliefs about biotechnology are very negative.
20

21
22 This group of students is less pronounced in their affective reactions. On the other hand,
23
24 they are very explicit in their behavioural intentions. This 'not for me'-group shows no
25
26 intentions of ever buying, eating or using anything made from or with modern
27
28 biotechnology. Only the intention towards the medical field is a little less negative
29
30 (Figure 1).
31
32

33 34 35 **Conclusions**

36
37
38 In the present study, the tripartite attitude model was used to explore the concept of
39
40 attitude towards biotechnology in all its features. In this section, the results will be
41
42 **summarised** and compared to former research. Some conclusions will be drawn and the
43
44 major implications for further research will be presented.
45
46

47
48 The results show that attitude towards biotechnology is a multi-component concept of
49
50 various cognitive, affective, and behavioural features. Different types of affective and
51
52 cognitive evaluations, two different types of content knowledge and three different types
53
54 of behavioural intentions interact and result in a specific set of four attitude patterns.
55
56
57
58
59
60

1
2
3 The **cognitive component** consists of a combination of content knowledge and a
4
5 cognitive evaluation. The results confirm two different types of knowledge on modern
6
7 biotechnology. The first type concerns content knowledge on biology and genetics,
8
9 referring to the basic concepts in this discipline. The second type concerns knowledge
10
11 and understanding of biotechnology applications. Cognitive evaluation refers to beliefs,
12
13 expectancies, and perceptions related to modern biotechnology.
14
15

16
17 Except for the 'not for me'-group of students the respondents in this study show
18
19 reasonable to very good content knowledge. This is quite different from the most
20
21 common findings in content knowledge towards biotechnology, which imply limited
22
23 understanding of concepts and implications of modern biotechnology (Osborne et al.,
24
25 2003; Dawson & Schibeci, 2003a). It is possible our study confirms the observed
26
27 progress in terms of basic scientific knowledge since the Eurobarometer of 1996 (Pardo
28
29 & Calvo, 2002). On the other hand, the cognitive evaluation (beliefs and expectancies) of
30
31 biotechnology seems rather negative. Especially the 'concerned sceptics' and the 'not for
32
33 me' groups evaluate the attributes of biotechnology in a negative sense. The confident
34
35 supporters, with the highest level of content knowledge are also most positive about the
36
37 attributes of biotechnology. However, this link between content knowledge and cognitive
38
39 evaluation only emerges in this group of supporters. In the other groups, content
40
41 knowledge does not seem to relate to cognitive evaluation. This is shown for example by
42
43 the fact that the 'not sure' group and the concerned sceptics do not differ in terms of their
44
45 knowledge, but they do differ in terms of their cognitive evaluation. These finding shows
46
47 the complex nature of the relationship between content knowledge and attitude towards
48
49 biotechnology. Although in general one may conclude that more content knowledge is
50
51
52
53
54
55
56
57
58
59
60

1
2
3 related to more positive cognitive evaluations, it also depends on other aspects of attitude
4
5 patterns such as affective evaluation and behavioural intentions.
6
7

8 In the **affective component**, three types of evaluations emerge. The first evaluation can
9
10 be described as a basic emotional reaction, the second reaction expresses feelings of
11
12 unavailability and the third revolves around worries. Students with clear positive basic
13
14 emotional reactions can be found in the group of 'confident supporters'. The 'concerned
15
16 sceptics' on the other hand seem to disagree with the stance of 'it is going to happen
17
18 anyway' combined with high level of concern and unease regarding biotechnology. The
19
20 remaining two clusters ('not sure' and 'not for me') are less pronounced in their affective
21
22 evaluations of biotechnology. As described in the introduction, other research on the
23
24 affective component of attitude often describes attitude in terms of a single dimension:
25
26 individuals either oppose or favour biotechnology. Our study has clearly shown that the
27
28 way people feel about biotechnology is a more complex issue.
29
30
31
32

33
34 The **behavioural component** is indicated by three types of intentions: 1) an intention to
35
36 consume because it serves one's own interests, 2) an intention to co-operate if it serves
37
38 medical purposes, and 3) an intention to consume if certain conditions are met, for
39
40 example, environmental issues. All groups seem to have different kinds or combinations
41
42 of intentions. For the 'confident supporter'-group the dominant intention is to consume
43
44 when it is in one owns interests. For the 'not sure'-group critical conditions seem most
45
46 important for deciding whether or not to become involved with applications of
47
48 biotechnology.
49
50
51

52
53 Both the 'not for me'-group and the group of 'concerned sceptics' do not seem likely to
54
55 engage with biotechnology at all. A difference between the two groups is that the
56
57
58
59
60

1
2
3 concerned sceptics show no intentions to make use of medical applications, whereas the
4
5 'not for me' group seems less reluctant to, for example, take a genetic test when pregnant.
6
7

8 The results of the Eurobarometer suggest that most European adults are supportive of
9
10 biomedical use of biotech. This is only in part confirmed by our results: the confident
11
12 supporters do seem to intend to engage with biomedical applications, but the remaining
13
14 groups are more reluctant.
15

16
17 In summary, the findings in our study confirm what is frequently assumed and
18
19 **emphasised** in studies on attitudes towards biotechnology (or science in general), namely
20
21 that the more one knows about the subject, the more positive one's feelings and the more
22
23 positive the behavioural intentions. This relationship between the three attitudinal
24
25 components is observed in the comparison of the 'confident supporters' versus the 'not
26
27 for me'-group. Nevertheless, this study also shows that in the largest group of students
28
29 ('not sure' and 'concerned sceptics'), a different pattern of relationship among the three
30
31 attitude components emerges. In these two largest groups, a reasonable to good cognitive
32
33 basis combines with negative or neutral affective responses and behaviour intentions.
34
35 These results clarify that with respect to a complex subject such as modern
36
37 biotechnology, each of the attitude components has its unique contribution to the overall
38
39 attitude.
40
41
42
43
44
45
46
47

48 One of the starting-points of our study was Pardo's argument about the necessity to
49
50 include a broad range of dimensions in 'modern biotechnology' and its implications, e.g.
51
52 predictive medicine, genetically modified food and cloning. All these dimensions are
53
54 important in showing what attitudes towards biotechnology bring about (Pardo *et al.*,
55
56
57
58
59
60

1
2
3 2002). We tried to cover most of these relevant dimensions in our **conceptualisation** of
4
5 attitude towards biotechnology. However, the results of the study by Verdurne and
6
7
8 Viaene (2003) on consumer beliefs and attitude towards GM-foods are rather similar to
9
10 our four clusters. This seems to imply that the public seems to react with similar
11
12 attitudinal patterns when GM-foods are considered, compared to when a broad range of
13
14 biotech applications are considered.
15
16

17
18
19 We have stated that research on attitudes towards modern biotechnology is important
20
21 given its expected impact on society. Citizens must be capable to make informed
22
23 decisions about issues affecting their own lives in the near future. They also should have
24
25 the opportunity to participate in decision-making processes based on a basic level of
26
27 understanding socially relevant developments in this field of science. In the light of these
28
29 scientific literacy goals, education is an important factor. Detailed information on what an
30
31 attitude towards modern biotechnology entails may serve as a basis for designing good
32
33 quality education. Our study has clearly shown that the way students think, feel and intent
34
35 to act with biotechnology is a complex issue.
36
37
38
39
40
41
42

43 *Future research*

44
45 The isolation of a person actual attitude is rather tricky since that person's attitude is
46
47 always incomplete and in a state of evolution, especially when they deal with extremely
48
49 complex subjects such as biotechnology is (Campbell et al., 1976; Pardo et al., 2002).
50
51 This has always been a problem for measuring a complex construct as attitude is. For this
52
53 reason it is important to replicate the present study in a large and truly random sample of
54
55
56
57
58
59
60

1
2
3 Dutch secondary school students. Furthermore, a replication in a sample drawn from the
4
5 general public would improve the possibility of generalization even more. In such a
6
7 sample, it would also be possible to examine the validity of the questionnaire, for
8
9 example by including actual behavioural measures.
10
11

12
13
14
15 A second line of future research concerns the research question on how attitudes patterns
16
17 towards biotechnology can be explained. General scientific interest may play a role, as
18
19 well as beliefs regarding science and technology, but also moral beliefs may explain why
20
21 students hold certain attitudes (Schibeci & Riley, 1986; Osborne et al., 2003). A number
22
23 of studies have found several background factors which influence the attitudes people
24
25 hold (Atwater & Simpson, 1984; Ajzen & Fishbein, 2000). Important background factors
26
27 are personal characteristics, such as religious background, ethnicity, educational level and
28
29 gender. It is interesting to examine whether group differences emerge in the concept of
30
31 attitude as defined in our present study.
32
33
34
35
36
37
38

39 *Implications for science teaching and communication*

40
41 Although limitations have to be taken into account, the findings of this study highlight
42
43 issues that may have to be considered by curriculum planners and science teachers who
44
45 wish to incorporate scientific literacy into science curricula. When educating students
46
47 about modern biotechnology and its implications, one has to keep in mind that students
48
49 hold different starting points when considering modern biotechnology. Not only should
50
51 science education focus on knowledge and understanding, but also on the affective side
52
53 of biotechnology. This change in emphasis might help students to create a more balanced
54
55
56
57
58
59
60

1
2
3 attitude towards biotechnology. These findings should be taken into account in the
4
5 development of educational programmes for secondary school students on informed
6
7 decision-making towards modern biotechnology.

Zeidler (Ed.), *The role of moral reasoning on socioscientific issues and discourse in science education*, pp. 7–38. Dordrecht: Kluwer Academic Press.

Table 1. Attitude factors with scale name, description, typical items, reliability and descriptive values, based on principal component analyses

Attitude components	Attitude factors	Description	Typical item	Cronbach's alpha (No. of items)	Mean (SD)
Cognitive component	Biology and genetics ¹	Knowledge of biology and genetics	DNA contains the information for all you hereditary factors.	0.63 (n = 9)	7.10 (1.8)
	Biotech ¹	Knowledge of biotech applications	Normal tomatoes have, in contrast to GM tomatoes, no genes.	0.71 (n = 17)	13.80 (1.8)
	Beliefs	Evaluative knowledge of biotech / beliefs about biotech	I think genomics can solve food problems in the third world	0.70 (n = 5)	3.09 (0.64)
Affective component	Basic emotion	Basic emotional reactions	Genetic modification (GM) is bad.	0.78 (n = 13)	3.00 (0.58)
	Unavoidable	Feelings of biotech being unavoidable	Biotechnology is absolutely necessary.	0.76 (n = 9)	3.12 (0.62)
	Worries	Worries about biotech	How many worries do you have about genetic research?	0.79 (n = 5)	2.97 (0.79)
Behavioural component	Own intentions	Consuming intentions; own interest	I would eat GM food if it was cheaper than normal food.	0.78 (n = 5)	3.09 (0.82)
	Medical intentions	Medical intentions	Would you take a genetic test during your pregnancy?	0.74 (n = 4)	3.10 (0.83)
	Critical intentions	Consuming intentions; critical conditions	I would buy GM food if it were grown more environment-friendly than normal food.	0.74 (n = 3)	3.60 (0.90)

¹ Bivariate data.

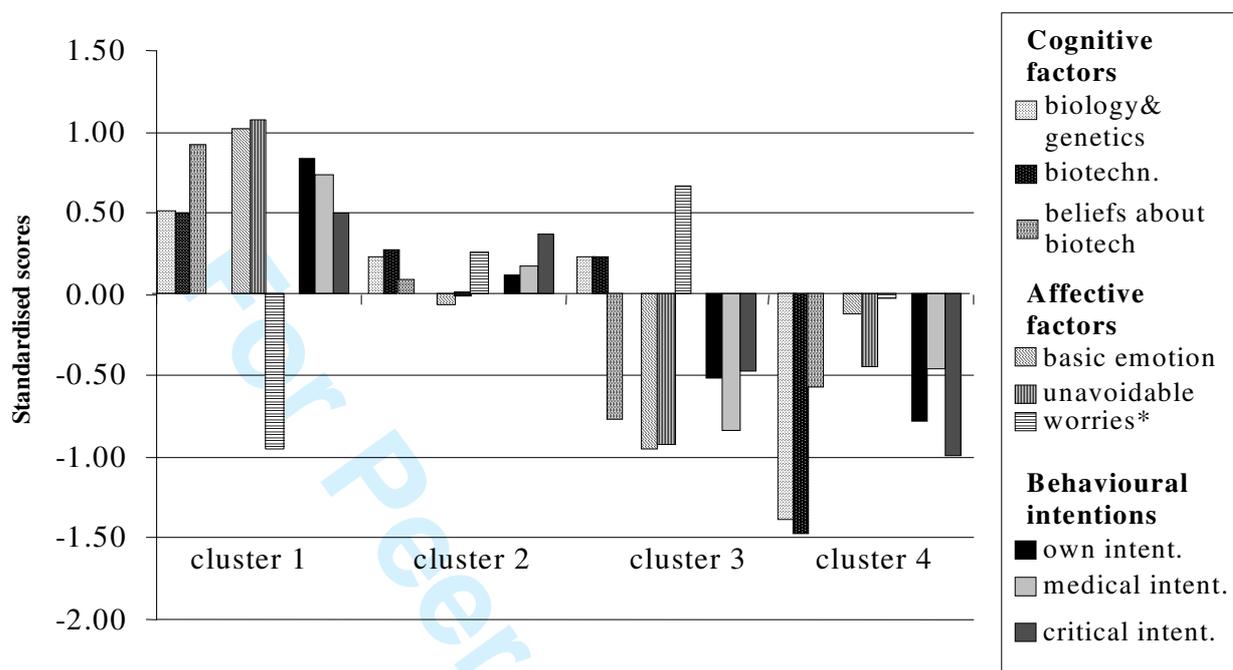

Figure 1. Results of k-means cluster analysis of 574 secondary school students' attitudes towards modern biotechnology, using a user-defined cluster number of four.

Cluster 1: confident supporter-cluster ($n = 130$); cluster 2: not sure-cluster ($n = 239$); cluster 3: concerned sceptic-cluster ($n = 105$); cluster 4: not for me-cluster ($n = 100$). Scores on the different factors of the three main attitudinal components are *standardised values*.

*Negative score on 'worries-factor' indicates fewer worries about modern biotechnology.
