Abstract: The design, synthesis and photophysical evaluation of four anthracene based photoinduced electron transfer (PET) sensors (**3a-d**) for anions is described. The $[4\pi+4\pi]$ photodimerization product, **4**, was also obtained from **3b**, by slow evaporation from DMSO solution and its X-ray crystal structure determined. The structure of **4**, showed the classical dimerization at the 9,10-positions of anthracene. Sensors **3a-d** are all based on the use of charge neutral aryl urea receptors, where the recognition of anions such as acetate, phosphate and iodide, was found to be due to the formation of strong hydrogen bonding interactions in DMSO. This anion recognition resulted in enhanced quenching of the anthracene excited state *via* electron transfer from the receptor; hence the emission was 'switched on-off'. The sensing of fluoride was, however, found to be a two-step process, which involved initial hydrogen bonding interactions with the receptor, followed by deprotonation and the formation of bifluoride (HF_2^-). The changes in the emission spectra upon sensing of chloride and bromide were, however, minor. The photophysical properties of these sensors in the presence of various anions were further studied, including investigation of their excited state lifetimes and

3 quantum yields, as well as detailed Stern-Volmer kinetic analysis with the aim of determining
4 the dynamic and static quenching constants, k_q and k_s for the above anion recognition. These
5 measurements indicated that while the anion dependant quenching was mostly by a dynamic
6 process, some contribution from static quenching was also observed at lower anion
7 concentrations.

17 INTRODUCTION

18
19 Over the years, much effort has been devoted to the development of selective and
20 sensitive optical chemosensors for real time detection of ions and molecules which are of
21 major interest in clinical analysis and diagnostics, biology and environmental chemistry.[1-3]
22 The sensing of anions has become an important area of research in supramolecular chemistry,
23 with many excellent examples being published in the last few years.[4-6] Particular emphasis
24 has been placed on the use of charge neutral anion receptors such as thioureas, ureas and
25 amidoureas, as well as amides and pyrroles as anion recognition moieties. The incorporation
26 of these into chromophores and fluorophores with the aim of developing colorimetric and
27 fluorescent sensors for anions has become an important area of research.[7-10] Gale *et al.*
28 have been at the forefront of such research and have recently used anion binding motifs such
29 as amidoureas in naked eye detection of biologically important anions, by incorporating these
30 binding moieties as integrated parts of 'push-pull' chromophores, as well as including such
31 anion recognition sites into macrocyclic structures.[11,12] Several other groups, such as
32 Pfeiffer *et al.*[13], He *et al.* [14], Fabbrizzi *et al.*[15] and Jiang *et al.* [16] have also used
33 similar aryl based ureas or thiourea architectures to achieve colorimetric sensing of anions. At
34 the same time, we developed the first examples of charge neutral PET sensors for anions
35 using thiourea receptors.[17] We have also developed sensors using aminourea based
36 receptors for the recognition of anions in aqueous solution, or by incorporating such binding

1
2
3 motifs into preorganized structural scaffolds such as calix[4]arene.[18] We have also
4
5 demonstrated the fixation of CO₂ as HCO₂⁻ by using colorimetric anion sensors based on the
6
7 naphthalimide fluorophore,[19] and have shown that lanthanide (Tb(III) or Eu(III))
8
9 luminescent complexes can be employed to detect aromatic or aliphatic mono and bis-
10
11 carboxylates in competitive media, or by using displacement assays. [20,21]
12
13
14

15 In our earlier work, which was centred on developing charge neutral fluorescent anion
16
17 sensors, we focused on the use of anthracene and naphthalimide based sensors, where the
18
19 changes in the fluorescence intensity of these sensors were monitored upon increased anion
20
21 concentration.[17,19] We showed that the recognition of these anions, on all occasions, gave
22
23 rise to reduced emission, which we describe as an 'on-off' emission changes. We proposed
24
25 that these changes were due to enhanced photoinduced electron transfer (PET) quenching of
26
27 the fluorophore excited state from the anion receptor, upon anion recognition. However, a
28
29 more comprehensive photophysical investigation into this phenomenon has not been carried
30
31 out in our laboratory, and with this in mind we set out to develop several new fluorescent PET
32
33 sensors using substituted urea receptors. These sensors, **3a-3d**, are all based on the classical
34
35 *fluorophore-spacer-receptor* model, where the aryl receptor is separated from the fluorophore
36
37 fluorophore by a short spacer.[22] These are also the first examples of such urea based
38
39 sensors from our laboratory.
40
41
42
43
44

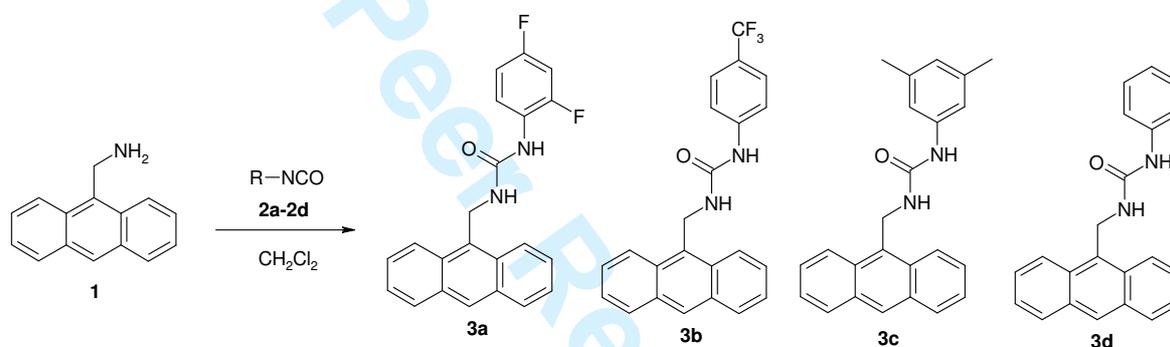

45 The urea receptors, **3a-3d**, were also selected in such a manner to gain further insight
46
47 into the effect that the aryl based receptors would have on: *a*) the binding affinity of the
48
49 receptor and *b*) the efficiency of the electron transfer quenching. Hence, questions such as do
50
51 the more electron withdrawing receptors give rise to stronger binding and hence more
52
53 efficient quenching than electron donating ones (as such inductive effects would make the
54
55 urea protons more acidic and hence, stronger hydrogen bonding donors), had not been fully
56
57 answered. Herein, we give a full account of our investigation, which involved the titration of
58

10 RESULTS AND DISCUSSION

11 Synthesis of compounds 3a-3d

12
13 The synthesis of the desired urea based sensors was achieved in high yield in a single step,
14
15 Scheme 1, from 9-aminomethyl anthracene, **1**, by reacting it with the commercially available
16
17 isocyanides: 2,4-difluorophenyl-, (**2a**), 4-(trifluoromethyl) phenyl-, (**2b**), 3,5-dimethylphenyl-
18
19 isocyanides: 2,4-difluorophenyl-, (**2a**), 4-(trifluoromethyl) phenyl-, (**2b**), 3,5-dimethylphenyl-

35
36
37 (**2c**) and phenyl- isocyanate, (**2d**), respectively, in dry CH₂Cl₂, at room temperature. In all
38
39 cases, upon addition of **2a-d** to **1**, creamy pale yellow precipitates were immediately
40
41 observed. Nevertheless, the reactions were left stirring overnight. The resulting precipitates
42
43 were then collected by suction filtration, washed several times with cold CH₂Cl₂ and dried
44
45 under high vacuum. Compounds **3a-d** were all obtained in yields of 80-97% after
46
47 recrystallisation from CHCl₃. All the compounds were characterised using conventional
48
49 methods (see experimental section). The sensors were partially soluble in CDCl₃, and fully
50
51 soluble in DMSO-*d*₆. In the latter solvent, two characteristic resonances were observed at 8.47
52
53 ppm and 8.45 ppm, for the urea protons of the electron deficient **3a**, while for the electron rich
54
55 sensor **3d** these protons appeared at 8.14 ppm and 6.61 ppm.

The X-ray crystal structure analysis of [2+2] photochemical adduct of **3b**

Several attempts were made to obtain crystals of the above sensors for X-ray crystal structure analysis. However, the use of slow evaporation or diffusion techniques failed on all occasions. In contrast, colourless crystals were obtained from an NMR sample of **3b**, in DMSO-*d*₆, and were found to be suitable for X-ray crystal structure analysis.[23,24] Although, to our

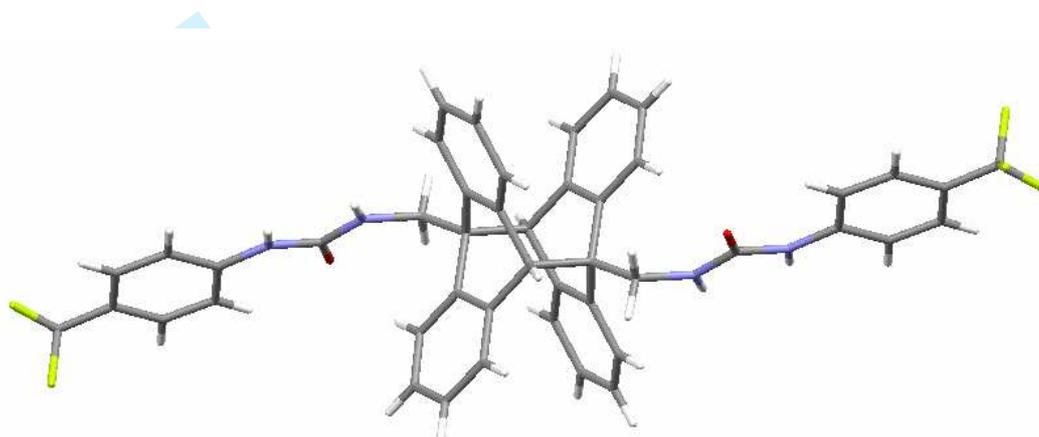

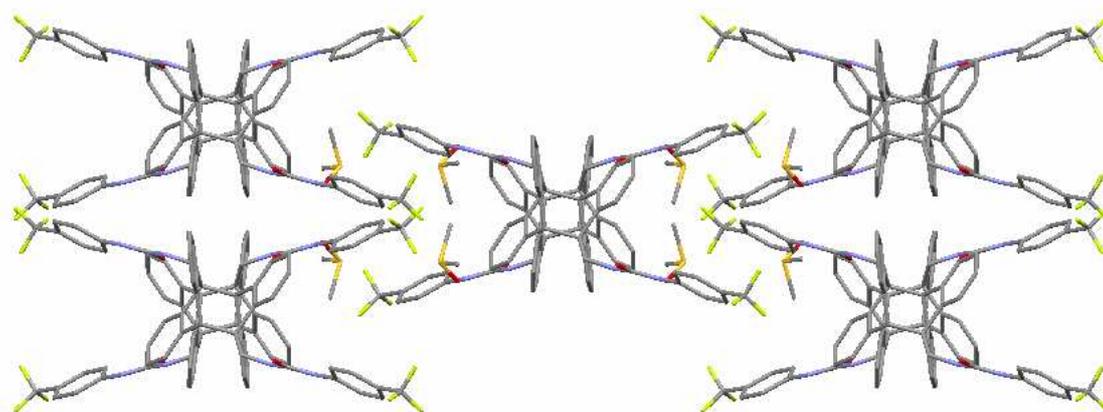

Figure 1. The X-ray crystal structure of the [4 π +4 π] cycloaddition product **4**, formed from **3b**. A DMSO molecule has been removed for clarity (see text).

surprise, the structure was not that of the desired sensor **3b**, but the product of the resulting [4 π +4 π] photocycloaddition dimerization reaction between two molecules of **3b**, *i.e.* **4**. The new bonds were formed between the central rings on each anthracene unit as is evident from Figure 1. It also shows that the structure adopts C₂ symmetry with the two urea receptors being *anti* to each other, with a single DMSO molecule being found in the unit cell. This structure can only be obtained photochemically, which is however, thermally reversible, and only from the desired compound **3b**. Hence, **4** can be viewed as being the proof of the formation of **3b**. This photochemical reaction is a common phenomenon for anthracene, which can be dimerized easily upon UV radiation.[25,26] However, the sample that these crystals were grown from was only exposed to halogen based room-light and/or sunlight. We therefore propose that the urea receptor activates the 9 position of the anthracene sensor **3b** in such a way that it dimerizes in this manner. The structure of **4**, is one of two possible structural isomers; the other being where the two receptors would be on the same side ('*syn*'

1
2
3 to each other) of the photodimerised product of **3b**. This is also known as the *head-to-tail*
4 product.[25,26] Compound **4**, is however, the so called tail-to-tail product, and is described as
5 being the more stable of the two isomers. It is usually the product isolated upon
6 photodimerization of such 9-substituted anthracene molecules. This is also believed to be the
7 more thermally reversible product. As is typical for such dimerization products, the four aryl
8 rings adopt a double wing like appearance, with a C...C bond length of 1.626(4) Å between
9 the two former anthracene 9 and 10 positions. Moreover, the bond angle between the C9-C30-
10 C17 atoms was found to be on average 113.1°, which is also typical for such products. The
11 structure also shows that the urea moieties are almost coplanar with the 4-(trifluoromethyl)
12 phenyl groups, with average N...H bond length of 0.860Å.

27 The packing diagram of **4** viewed down the crystallographic c axes can be seen in
28 Figure 2. This shows that each of the urea moieties is hydrogen bonded to the oxygen of an
29 aforementioned DMSO molecule, with a O...H bond length of 2.95 Å. However, even

54 though the 4-(trifluoromethyl) phenyl groups show evidence of stacking, the distance between
55 the two aryl groups is 8.7Å, which is too long to account for any π - π stacking interactions.
56
57
58
59
60
There is however, a further F...H interaction between the aryl CF₃ groups and the protons of

the DMSO molecules with average F...H distance of 2.66 Å. The anion recognition ability of this structure was not evaluated.

Photophysical evaluation of 3a-3d

The photophysical properties of the four sensors were evaluated in DMSO. The ground state properties of **3a-3d** were first investigated. The absorption spectra of all the sensors were almost identical, when recorded in DMSO, with bands appearing at 340, 369 and 324 nm, respectively, and a shoulder at 333 nm which was assigned to the aryl groups of the receptor moieties. These are significantly shifted towards the red in comparison with anthracene, which has three characteristic bands appearing at 342, 360 and 380 nm, respectively.[27] For these four sensors, extinction coefficients of 9920, 10830, 7279 and 9560 [Mol⁻¹cm⁻¹] were determined in DMSO for **3a-3d**, respectively.

Using for excitation, the 369 nm transition of the anthracene based sensors, and the 360 nm band of the reference anthracene chromophore, the fluorescence emission spectra were recorded in DMSO. Here, the characteristic fluorescence emission of the anthracene fluorophore was observed for all the compounds, with that of the sensors being red-shifted by

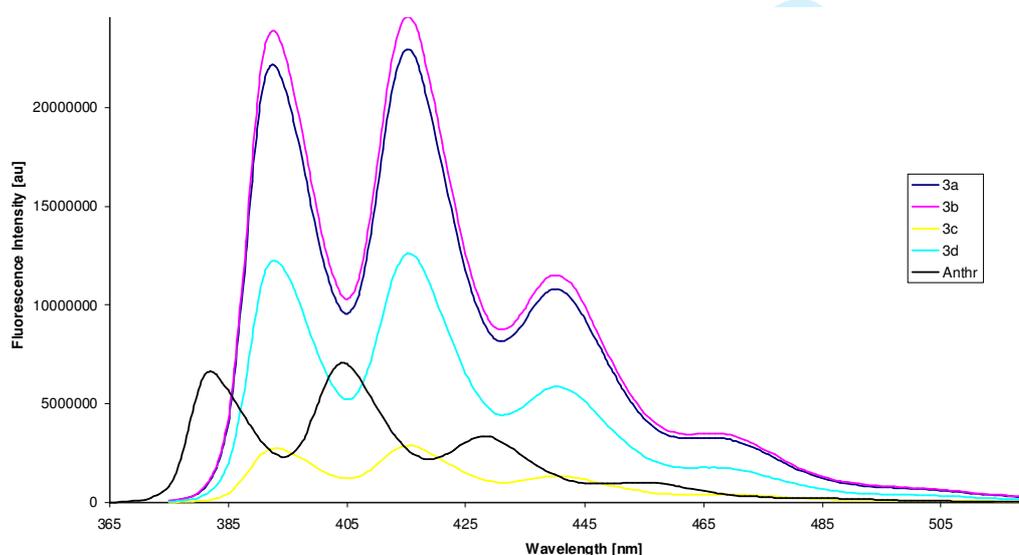

Figure 3. Comparison between the fluorescence emission spectra of chemosensors **3a-d** and the spectrum of anthracene, **Anthr**, in DMSO.

1
2
3 *ca.* 10 nm in comparison with that of anthracene itself, Figure 3, emitting at 393, 415 and 440
4 nm, with a shoulder at 466 nm. As can be seen from Figure 3, the intensity of all the sensors,
5
6 with the exception of **3c**, was greater than that of the reference anthracene compound. For **3a-**
7
8 **3d** the quantum yields of fluorescence (Φ_F) were determined as 0.53, 0.57, 0.06 and 0.33,
9
10 respectively under these experimental conditions, where the order is **3a>3b>3d>3c**, which
11
12 shows that the more electron withdrawing substituents give rise to the higher quantum yields.
13
14 This follows a known trend, where 9,10-dimethyl anthracene has a higher quantum yield than
15
16 9-methyl-anthracene, which subsequently has higher quantum yield than anthracene itself.
17
18 However, and perhaps somewhat surprising, then it is worth noting that in the case of **3c**, the
19
20 di-substitution at the aryl ring gives rise to a very low quantum yield in comparison the rest of
21
22 the sensors. A similar trend was seen for the fluorescence lifetimes (τ_F) in DMSO. The decays
23
24 upon excitation of the 356 nm transition and observation at 450 nm were all single
25
26 exponential, and had lifetimes 7.83, 8.99, 1.32 and 4.96 ns, respectively for the sensors **3a-3d**.
27
28 From these changes, the rate constants for fluorescence k_F , can be determined, as being
29
30 6.76×10^7 , 6.34×10^7 , 4.55×10^7 and $6.67 \times 10^7 \text{ s}^{-1}$ for **3a-3d**, respectively. From these results it is
31
32 clear, that even though there is no significant difference in either the λ_{Absmax} or λ_{Fmax} for these
33
34 sensors, the anion urea receptors have a significant effect on both Φ_F and τ_F . This is most
35
36 pronounced for the electron rich reporter system **3c**, where Φ_F and τ_F are significantly lower
37
38 than that observed for the remaining sensors. This is most likely to be due to a more efficient
39
40 photoinduced electron transfer quenching of the anthracene excited state by **3c**, in its 'free'
41
42 form (in the absence of any anions), while the electron withdrawing substituents of **3a** and **3b**
43
44 make the aromatic urea electron deficient and hence less able to participate in PET quenching.
45
46 This is supported by the fact that the results obtained for sensor **3d**, follow this trend, where
47
48 both the Φ_F and τ_F are smaller than that of **3a** and **3b**, but larger than that of **3c**. It is also
49
50
51
52
53
54
55
56
57
58
59
60

worth noting that **3a** and **3b**, which have electron withdrawing substituents on their receptors, seem to have very similar photophysical properties.

Anion binding evaluations of compounds **3a-3d**

Having established the fundamental photophysical properties of compounds **3a-3d**, the four compounds synthesised above were evaluated for their ability to detect anions in DMSO, by observing the changes in both the absorption and fluorescence emission spectra upon titrating these sensors with stock solutions of AcO^- , H_2PO_4^- , F^- , Cl^- , Br^- and I^- (as their tetrabutyl ammonium salts). Upon titration of these sensors with anions such as AcO^- , H_2PO_4^- , F^- , only minor changes were seen in the absorption spectra for the anthracene component at longer wavelengths, while more significant changes were seen at shorter wavelengths. While

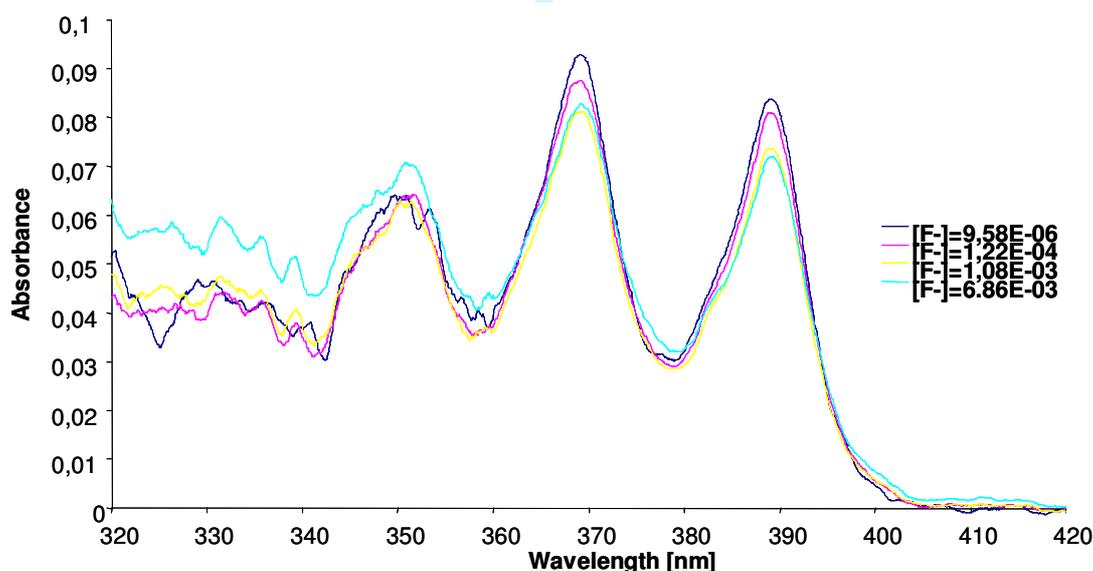

Figure 4. The changes in the absorption spectra of **3a** upon titration with F^- upon excitation of 369 nm, in DMSO.

these latter changes were assigned to the interaction of the anion at the urea receptor, the lack of changes in the anthracene transitions is not all together surprising as the methylene spacer should prevent any significant ground state interactions between the two parts. This is clear from Figure 4 which shows the titration of **3a** with F^- , where the major changes in the

absorption spectra occur at short wavelengths, indicating direct interaction between the receptor and the anion through hydrogen bonding.

Similar results were observed for H_2PO_4^- . When these measurements were made using AcO^- the changes in the shorter wavelengths were more pronounced. In comparison to these changes, the absorption spectra of **3a-3d** were not affected by the addition of either Cl^- or Br^- . However, upon titration of these sensors with I^- no significant changes were observed in the absorption spectra at low and medium concentrations ($0 \rightarrow 3 \text{ mM}$), while at high concentrations ($\sim 0.02\text{M}$) the fine structure of the absorption spectra was displaced by an intense, broad structure, signifying strong ground state interactions between these sensors and I^- under these conditions. In general, the changes in the absorption spectra of the fluorophore, with the exception of I^- can be considered to be minor and only the changes at short wavelengths, assigned to that of the receptor are affected. This indicates that anions such as AcO^- , H_2PO_4^- , F^- only interact with the receptor part of the sensors and that the methylene spacer prevents any ground state interactions between the fluorophore and the receptor.

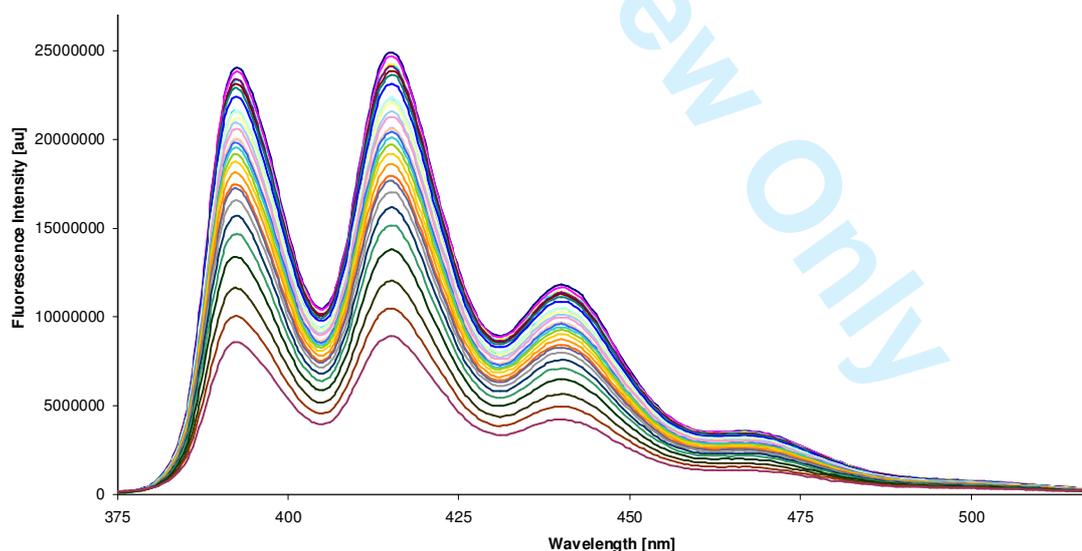

Figure 5. Fluorescence emission of **3a** titrated with TBAAcO, from top to bottom $[\text{AcO}^-] = 0$ to $6.27 \times 10^{-2} \text{ M}$. From values of the fluorescence intensity at 415nm the value for the quenching extent was measured to be *ca.* 64%.

1
2
3 Hence, it can be concluded that these urea based sensors behave as 'ideal' PET sensors for
4
5 anions.
6

7
8 In contrast to the changes in the absorption spectra, the anthracene based emission was
9
10 significantly modulated upon titration with the above anions in DMSO. The changes observed
11
12 for the titration of **3a** with AcO^- , is shown in Figures 5. It clearly demonstrates that the
13
14 emission is quenched upon addition of AcO^- , signifying the recognition of the anion at the
15
16 receptor side. It is also noticeable, that only the intensity of fluorescence is modulated and no
17
18 significant changes are observed in the positions of the three characteristic anthracene
19
20 emission bands. It can thus be concluded that these sensors behave as PET sensors, where the
21
22 emission of the fluorophore is quenched by PET from the receptor to the excited state of the
23
24 fluorophore.
25
26
27

28
29 Unlike that observed for classical PET cation sensors, where the emission is enhanced
30
31 due to the suppression of PET, caused by the increased oxidation potential of the receptor
32
33 upon cation recognition, the emission here is reduced. This can be viewed as a result of the
34
35 formation of a more electron rich anion-receptor complex, which gives rise to the
36
37 enhancement of the reduction potential. As Figure 5 demonstrates, the changes in the
38
39 emission spectra were homogenous across all the wavelengths, *i.e.* no particular transition was
40
41 more reduced than the other. Consequently, by observing the changes in the 414 nm transition
42
43 as a function of $\log[\text{AcO}^-]$, a sigmoidal plot was obtained, from which a binding constant \log
44
45 β was determined to be *ca.* 2. By plotting $\text{Log} [(I_{\text{max}}-I_{\text{F}})/(I_{\text{F}}-I_{\text{min}})]$ as a function of $\log[\text{AcO}^-]$,
46
47 a linear plot ($R^2 = 0.92$) was observed from which a $\log \beta = 2.14 (\pm 0.1)$ was determined.[28]
48
49
50 This indicates a weak binding between the sensor and the anion. When the same titrations
51
52 were carried out using **3b-3d**, similar luminescent changes were observed, where the emission
53
54 was quenched upon increasing anion concentration, without any measurable changes in λ_{max} .
55
56
57 From these changes, binding constants of $2.44(\pm 01)$, $2.07(\pm 01)$ and $2.09(\pm 01)$ were
58
59
60

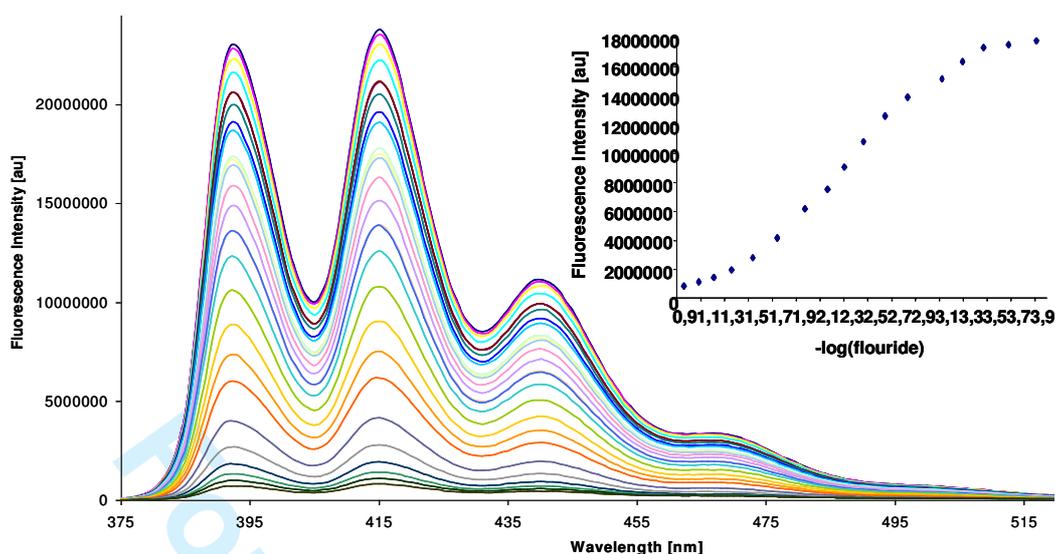

Figure 6. Fluorescence titration spectra showing the changes in fluorescence emission of **3a** in DMSO upon addition of fluoride, from top to bottom, $[F^-] = 0 \rightarrow 1.1 \times 10^{-1}$ M. Insert: The changes in the 415 nm transition as a function of $[F^-]$.

determined, for **3b-3d**, respectively. However, for all of these the quenching was more efficient than seen for **3a**, being 81%, 70% and 83% for these three sensors, respectively. The effect of the substituent on the aryl urea receptor can also be seen from these changes. However, these are not as dramatic as one would anticipate. While the binding affinity follows the trend of **3b**>**3a**>**3c** ~**3d**, displaying a marginally stronger binding for the two electron deficient receptors, there is no significant difference in these values. Hence, while the electron withdrawing groups would be expected to make the urea protons more acidic and as such, better hydrogen receptor, the difference in the binding constants does not reflect this. When these titrations were repeated using $H_2PO_4^-$, similar effects were observed. However, the degree of quenching was less, being 50%, 65%, 60% and 57% for the four sensors, respectively. From these changes binding constants ($\log \beta$) of $1.91(\pm 0.1)$, $2.11(\pm 0.1)$, $1.90(\pm 0.1)$, and $1.96(\pm 0.1)$, were determined which follow the same trend as seen previously for acetate. When either Cl^- or Br^- were used, the emission was only partially quenched, and only at high concentrations. However, these changes were too small for accurate binding constant determination. We assign this quenching to the formation of a hydrogen bonding

1
2
3 complex between the anion and the receptor rather than being due to heavy atom affect
4
5 quenching.
6

7
8 The titration of **3a-3d**, using F^- gave similar luminescent changes, *e.g.* no spectral
9
10 shifts were observed and only the fluorescence emission was quenched, demonstrating
11
12 effective PET quenching from the receptor upon anion recognition. However, unlike that seen
13
14 above, the emission was almost fully quenched. This can be seen in Figure 6, for **3a**, which
15
16 shows that the anthracene emission is reduced by almost 90% at the end of the titration.
17
18 Similarly, the emission was quenched for **3b-3d**, where it was reduced by *ca.* 97%, 91% and
19
20 97%, respectively. From these changes, the binding constants $\log \beta$ of 2.73(± 0.1), 3.26(± 0.1),
21
22 2.59(± 0.1) and 2.99(± 0.1), were determined.
23
24
25
26

27 While the same trend is observed here as above, the binding constants as well as the
28
29 efficiency of the quenching are significantly higher than seen for either AcO^- or $H_2PO_4^-$. We
30
31 have previously postulated that this is due to two main phenomena. Firstly, the small ion has
32
33 higher charge density than either AcO^- or $H_2PO_4^-$ and can form stronger hydrogen bonding
34
35 complexes with the receptor. Secondly, F^- is a good base in DMSO.[27] Consequently, F^-
36
37 can possibly deprotonate the urea receptor. This, has been shown to occur through a two step
38
39 mechanism, which gives rise to the formation of bifluoride, HF_2^- , the formation of which can
40
41 be monitored by NMR.[29] Moreover, the formation of such species in anion complexes has
42
43 recently been demonstrated using X-ray crystallography.[30] This deprotonation results in the
44
45 formation of a highly electron rich receptor, which consequently is also a more efficient PET
46
47 quencher. It is also possible that the HF_2^- products form a very strong ground state complex
48
49 with the receptor. With the aim of firmly establishing the nature of the quenching, we decided
50
51 to determine the rate of the quenching process for all of the sensors using the aforementioned
52
53 anions.

Kinetics of fluorescence quenching

In order to obtain the quenching rate constants, k_q , from fluorescence intensity measurements at different anion concentrations, $[Q]$, the Stern-Volmer kinetics was followed, **Equation (1)**, where I_0 and I are the fluorescence emission in the absence of quencher (anion) and for a given concentration of anion $[Q]$, respectively, K_{sv} and k_q are the Stern-Volmer and quenching rate constants respectively ($K_{sv} = k_q \tau_0$) and τ_0 is the lifetime in the absence of quencher.[27] Here the plot of I_0/I versus the anion concentration should be linear with a slope equal to $k_q\tau_0$. In Figure 7, the results for the titration of **3a** with F^- are shown. A

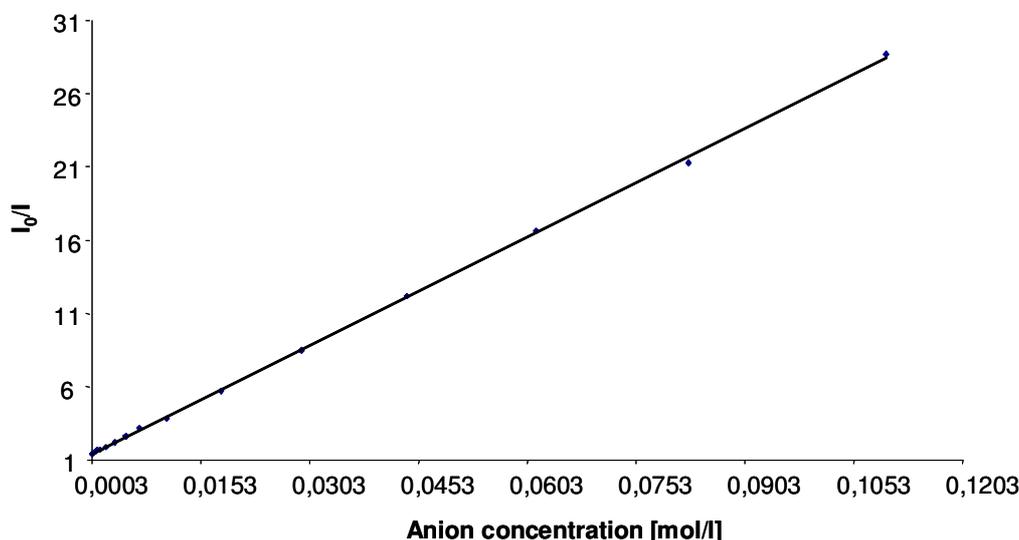

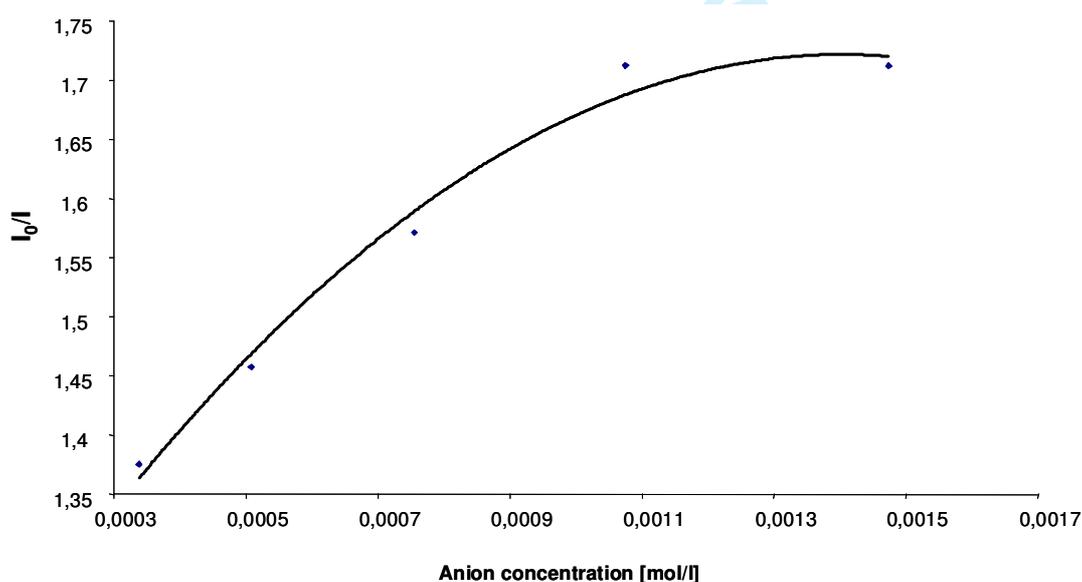

Figure 7. Stern-Volmer plot for the fluorescence quenching of **3a** by F^- . The solid line translates the theoretical curve from the Stern-Volmer **Equation (1)**. Quantitative analysis of the data, based on **Equation (1)**, yielded a Stern-Volmer constant, $K_{sv} = 246.68 \text{ M}^{-1}$. The fluorescence lifetime of **3a**, τ_0 , was previously determined as being 7.83 ns. Using this lifetime, the quenching constant was found to be $k_q = 3.15 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$. The good correlation coefficient obtained leads us to believe that, apparently, a linear behaviour was followed.

$$\frac{I_0}{I} = (1 + K_{sv}[Q]) = (1 + k_q \tau_0 [Q]) \quad (1)$$

1
2
3
4
5
6 However, a more detailed study of the Stern-Volmer plot shows that this linearity was not in
7
8 fact apparent at a low concentration of F^- . As can be seen in Figure 8, the linear behaviour of
9
10 the Stern-Volmer equation was not observed on the titration of **3a**. This observation can be
11
12 stated, not only to this experiment, but to all our other experiments. The deviation of the
13
14 Stern-Volmer equation from linearity can be explained if we consider an alternative
15
16 quenching process to the dynamic quenching. Hence, the quenching of the fluorescence
17
18 emission can also arise from static quenching, which can be considered to be due to the
19
20 interaction between the receptor and the sensor in the ground state, prior to excitation, or
21
22 dynamic quenching, with formation of a complex between the excited sensor, and the anion
23
24 receptor. Because of this, both the static and dynamic quenching effects were taken into
25
26 account in the modified Stern-Volmer equation, **Equation (2)**, where k_s is an equilibrium
27
28 constant for the static quenching. [31]
29
30
31
32

$$\frac{I_0}{I} = (1 + K_{SV}[Q])(1 + k_s[Q]) = 1 + (k_s + k_q\tau_0)[Q] + k_s k_q \tau_0 [Q]^2 \quad (2)$$

Figure 8. Fraction of the Stern-Volmer plot for the fluorescence quenching of **3a** upon anion, F^- , titration

Using this equation, the kinetics of the fluorescence quenching were re-fitted, by using τ_0 , 7.83×10^{-9} s and both the dynamic and static quenching constants, k_q and k_s , determined. For these changes, the values for k_q and k_s were found to be: $k_q = 3.09 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$, $k_s = 0.22 \text{ M}^{-1}$. Even though these are not very significant, from what we observed above, the results do suggest the presence of the static quenching which implies that the sensor is interacting with the anion both in the ground and excited state with a dynamic quenching rate constant close to the diffusion controlled values.

In order to differentiate the dynamic quenching constant obtained using **Equation (1)** from the one obtained using **Equation (2)**, the terms k_{qsv} and k_q were used respectively. The values of K_{sv} and consequently k_{qsv} (dynamic quenching constant based on $K_{sv} = k_{qsv} \tau_0$), k_q and k_s found for the fluorescence titrations of **3a-d** with F^- , I^- , AcO^- and $H_2PO_4^-$, following the same method, are summarised in **Table 1**. Since the lifetimes are not dependent on the static quenching, the fluorescence lifetimes shown in **Table 1** for **3a-3d** as a function of the anion concentrations have been measured and analysed according to the **Equation (3)**, where τ_0 and τ are respectively the lifetimes in the absence and presence of quencher (same as reported above).

$$\frac{\tau_0}{\tau} = 1 + k_q \tau_0 [Q] \quad (3)$$

Table 1. Results from the kinetic investigation for the anion induced quenching of **3a-3d**.

Sensor	τ_0 [ns]	Anion	K_{sv} [M^{-1}]	k_{qsv} [$\text{M}^{-1} \text{s}^{-1}$]	k_q [$\text{M}^{-1} \text{s}^{-1}$]	k_s [M^{-1}]

K_{sv} and consequently k_{qsv} , k_q and k_s values found for the fluorescence titrations of **3a-d** with *F*⁻, *I*⁻, *AcO*⁻ and *H₂PO₄*⁻. *All these values were taken as module as the values were found, following the method described above, to be negative.

From the results in Table 1, it is clear that the fluoride anion gives rise to large K_{sv} , even though its value changes dramatically within this set of sensors. Moreover, these values are about an order of magnitude greater than diffusion control. This is, probably due to, and as discussed earlier, the fact that there is some degree of ion pairing of bifluoride with the receptor. With the exception of *I*⁻, which has significant ground state interactions with the fluorophores, the same order was observed (as expected) as above with *AcO*⁻ > *H₂PO₄*⁻. These results also show that the quenching is on all occasion fast and dominated by dynamic quenching, except at low concentrations.

CONCLUSION

We have synthesised several new simple fluorescent PET anion sensors, **3a-d**. These were characterised using conventional techniques as well as the crystal structure of the dimerized $[4\pi+4\pi]$ photocycloaddition product of **3b**. These sensors display 'ideal' PET behaviour upon

1
2
3 anion recognition, since only the fluorescence emission is “switched off” in the presence of
4
5 H_2PO_4^- , AcO^- , and F^- in DMSO. Hence, the changes in the ground state were only minor and
6
7 occurred at short wavelengths, which we associate with the interactions of the anions with the
8
9 receptor, which modulates the receptors redox potential. These sensors also showed good
10
11 selectivity with AcO^- being recognised over H_2PO_4^- . Nevertheless, **3a-d** all showed higher
12
13 affinity and more efficient quenching for F^- . This is not all together surprising since fluoride
14
15 high charge density and small size enables it to form strong hydrogen bonds with the urea
16
17 receptor. Moreover, the anion can deprotonate the receptors, forming HF_2^- which makes the
18
19 receptor a significantly stronger electron donor and hence an efficient quencher. We also
20
21 observed significant changes for the titration of **1**. However, these were deemed to be mainly
22
23 due to ground state interactions between the sensor and the anion. The absorption spectra of
24
25 all the sensors were shifted to longer wavelengths in comparison to anthracene. Moreover, all
26
27 the sensors, with the exception of **3c**, gave rise to larger quantum yields of fluorescence, and
28
29 were also red shifted. A more detailed evaluation of the quenching process using the Stern-
30
31 Volmer equation showed that generally the expected linearity was upheld confirming
32
33 dynamic quenching. However, closer examination for all the anions showed that at lower
34
35 anion concentration, static quenching was also observed.

EXPERIMENTAL

General:

Reagents (obtained from Aldrich) and solvents were purified using standard techniques. Melting points were determined using a Gallenkamp melting point apparatus. Infrared spectra were recorded on a Mattson Genesis II FTIR spectrophotometer equipped with a Gateway 2000 4DX2-66 workstation. ^1H NMR spectra were recorded at 400 MHz using a Bruker Spectrospin DPX-400 instrument. ^{13}C NMR spectra were recorded at 100 MHz using a Bruker Spectrospin DPX-400 instrument.

Spectroscopic studies:

All measurements were made at room temperature. Fluorescence spectra were measured using a Jovin Ivon-Spex-Fluorolog 3-2.2; the excitation wavelength was 369 nm, the excitation and emission slit widths were 0.5 mm. Emission spectra were corrected for the instrumental response of the system. The absorption spectra were recorded on a Shimadzu UV-2100 spectrophotometer. All absorption and fluorescence spectra were obtained from a solution of the sensor in DMSO in both the absence and the presence of anion guests. The effect of anions on the sensors was investigated by addition of different volumes of an anion (Br^- , Cl^- , I^- , F^- , AcO^- , H_2PO_4^-) solution in DMSO, with different concentrations (10^{-5}M to 1M), to a 2ml solution of **3a-d** in DMSO. In each case, for the fluorescence spectra, additions were accompanied with magnetic stirring. All titrations were repeated two times to ensure reproducibility. All the anions were used in the form of their tetrabutylammonium salts [(TBA), $(\text{C}_4\text{H}_9)_4\text{N}^+$]. These salts were purchased from Aldrich and used without further purification. DMSO was purchased from Riedel-Häen and stored over molecular sieves prior to use.

1
2
3 Fluorescence decay measurements were carried out using a home-built TCSPC apparatus with
4 an N₂ filled IBH 5000 coaxial flash lamp as excitation source, Jobin-Ivon monochromators,
5
6
7
8 Philips XP2020Q photomultiplier, and Canberra instruments TAC and MCA. [32, 33]
9
10 Alternate measurements (1000 c.p.c.) of the pulse profile at 356 nm and the sample emission
11
12 were performed until 1-2 × 10⁴ counts at the maximum were reached. The fluorescence
13
14 decays were analyzed using the modulating functions method of Striker with automatic
15
16 correction for the photomultiplier “wavelength shift” [34]. The method used to determine the
17
18 fluorescence quantum yields of compounds **3a-d** (Φ_F^C) involve a connection between the
19
20 fluorescence quantum yield of a reference (Φ_F^{ref}) and Φ_F^C . Anthracene was the reference used
21
22 ($\Phi_F^{\text{ref}} = 0.27$, in ethanol (EtOH), [35]). Firstly absorbance of the reference, in EtOH, and
23
24 compounds, in DMSO, were adjusted to similar values (below 0.10) at the excitation
25
26 wavelength. After this, the fluorescence spectra were recorded, under identical experimental
27
28 conditions, and a comparison was made between the integrated areas under the fluorescence
29
30 spectra of both the reference and the compounds. At last the **Equation (4)** was followed in
31
32 order to obtain the Φ_F^C values [35], where A_{ref} and A_C are respectively the

containing the compound (DMSO), $n_{\text{DMSO}} = 1.4793$ and the reference (EtOH), $n_{\text{DMSO}} = 1.3611$.

[27]

Synthesis:

9-Aminomethyl anthracene, **1** (0.1 g, 4.83×10^{-4} mol) was dissolved in ca. 5 mL of freshly distilled dry CH_2Cl_2 . To this solution 1.1 equivalent of the appropriate isocyanate in a single portion was added. Off-white or light yellow precipitates were immediately formed upon addition of the isocyanate. The reaction was allowed to stir for several hours, before the precipitate was isolated by filtration, washed with dry CH_2Cl_2 and dried under high vacuum (over P_2O_5) and eventually recrystallised from CHCl_3 to give powders.

1-Anthracen-9-ylmethyl-3-(2,4-difluoro-phenyl)-urea (**3a**)

Was obtained as an off-white solid in 80% yield. MS (ES^+) $m/z = 385.11$ [$\text{M} + \text{Na}$]. Abstract: The design, synthesis and photophysical evaluation of four anthracene based photoinduced electron transfer (PET) sensors (**3a-d**) for anions is described. The $[4\pi+4\pi]$ photodimerization product, **4**, was also obtained from **3b**, by slow evaporation from DMSO solution and its X-ray crystal structure determined. The structure of **4**, showed the classical dimerization at the 9,10-positions of anthracene. Sensors **3a-d** are all based on the use of charge neutral aryl urea receptors, where the recognition of anions such as acetate, phosphate and iodide, was found to be due to the formation of strong hydrogen bonding interactions in DMSO. This anion recognition resulted in enhanced quenching of the anthracene excited state *via* electron transfer from the receptor; hence the emission was 'switched on-off'. The sensing of fluoride was, however, found to be a two-step process, which involved initial hydrogen bonding interactions with the receptor, followed by deprotonation and the formation of bifluoride (HF_2^-). The changes in the emission spectra upon sensing of chloride and bromide were, however, minor. The photophysical properties of these sensors in the presence of various anions were further studied, including investigation of their excited state lifetimes and

3 quantum yields, as well as detailed Stern-Volmer kinetic analysis with the aim of determining
4 the dynamic and static quenching constants, k_q and k_s for the above anion recognition. These
5 measurements indicated that while the anion dependant quenching was mostly by a dynamic
6 process, some contribution from static quenching was also observed at lower anion
7 concentrations.

17 INTRODUCTION

18
19 Over the years, much effort has been devoted to the development of selective and
20 sensitive optical chemosensors for real time detection of ions and molecules which are of
21 major interest in clinical analysis and diagnostics, biology and environmental chemistry.[1-3]
22 The sensing of anions has become an important area of research in supramolecular chemistry,
23 with many excellent examples being published in the last few years.[4-6] Particular emphasis
24 has been placed on the use of charge neutral anion receptors such as thioureas, ureas and
25 amidoureas, as well as amides and pyrroles as anion recognition moieties. The incorporation
26 of these into chromophores and fluorophores with the aim of developing colorimetric and
27 fluorescent sensors for anions has become an important area of research.[7-10] Gale *et al.*
28 have been at the forefront of such research and have recently used anion binding motifs such
29 as amidoureas in naked eye detection of biologically important anions, by incorporating these
30 binding moieties as integrated parts of 'push-pull' chromophores, as well as including such
31 anion recognition sites into macrocyclic structures.[11,12] Several other groups, such as
32 Pfeiffer *et al.*[13], He *et al.* [14], Fabbrizzi *et al.*[15] and Jiang *et al.* [16] have also used
33 similar aryl based ureas or thiourea architectures to achieve colorimetric sensing of anions. At
34 the same time, we developed the first examples of charge neutral PET sensors for anions
35 using thiourea receptors.[17] We have also developed sensors using aminourea based
36 receptors for the recognition of anions in aqueous solution, or by incorporating such binding

1
2
3 motifs into preorganized structural scaffolds such as calix[4]arene.[18] We have also
4
5 demonstrated the fixation of CO₂ as HCO₂⁻ by using colorimetric anion sensors based on the
6
7 naphthalimide fluorophore,[19] and have shown that lanthanide (Tb(III) or Eu(III))
8
9 luminescent complexes can be employed to detect aromatic or aliphatic mono and bis-
10
11 carboxylates in competitive media, or by using displacement assays. [20,21]
12
13
14

15 In our earlier work, which was centred on developing charge neutral fluorescent anion
16
17 sensors, we focused on the use of anthracene and naphthalimide based sensors, where the
18
19 changes in the fluorescence intensity of these sensors were monitored upon increased anion
20
21 concentration.[17,19] We showed that the recognition of these anions, on all occasions, gave
22
23 rise to reduced emission, which we describe as an 'on-off' emission changes. We proposed
24
25 that these changes were due to enhanced photoinduced electron transfer (PET) quenching of
26
27 the fluorophore excited state from the anion receptor, upon anion recognition. However, a
28
29 more comprehensive photophysical investigation into this phenomenon has not been carried
30
31 out in our laboratory, and with this in mind we set out to develop several new fluorescent PET
32
33 sensors using substituted urea receptors. These sensors, **3a-3d**, are all based on the classical
34
35 *fluorophore-spacer-receptor* model, where the aryl receptor is separated from the fluorophore
36
37 fluorophore by a short spacer.[22] These are also the first examples of such urea based
38
39 sensors from our laboratory.
40
41
42
43
44

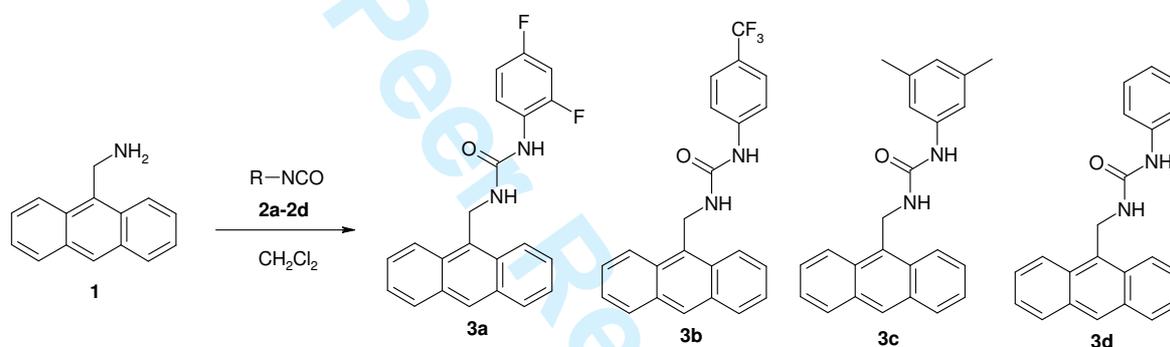

45 The urea receptors, **3a-3d**, were also selected in such a manner to gain further insight
46
47 into the effect that the aryl based receptors would have on: *a*) the binding affinity of the
48
49 receptor and *b*) the efficiency of the electron transfer quenching. Hence, questions such as do
50
51 the more electron withdrawing receptors give rise to stronger binding and hence more
52
53 efficient quenching than electron donating ones (as such inductive effects would make the
54
55 urea protons more acidic and hence, stronger hydrogen bonding donors), had not been fully
56
57 answered. Herein, we give a full account of our investigation, which involved the titration of
58
59
60

1
2
3 **3a-3d** with various anions and observing the changes in the various photophysical properties
4
5 of these compounds upon anion sensing.
6
7
8
9

10 RESULTS AND DISCUSSION

11 Synthesis of compounds **3a-3d**

12
13 The synthesis of the desired urea based sensors was achieved in high yield in a single step,
14
15 Scheme 1, from 9-aminomethyl anthracene, **1**, by reacting it with the commercially available
16
17 isocyanides: 2,4-difluorophenyl-, (**2a**), 4-(trifluoromethyl) phenyl-, (**2b**), 3,5-dimethylphenyl-
18
19 isocyanides: 2,4-difluorophenyl-, (**2a**), 4-(trifluoromethyl) phenyl-, (**2b**), 3,5-dimethylphenyl-
20
21

34 **Scheme 1.** Synthesis of the urea based anion sensors **3a-3d**. See text for **2a-2d**.

35
36
37 (**2c**) and phenyl- isocyanate, (**2d**), respectively, in dry CH₂Cl₂, at room temperature. In all
38
39 cases, upon addition of **2a-d** to **1**, creamy pale yellow precipitates were immediately
40
41 observed. Nevertheless, the reactions were left stirring overnight. The resulting precipitates
42
43 were then collected by suction filtration, washed several times with cold CH₂Cl₂ and dried
44
45 under high vacuum. Compounds **3a-d** were all obtained in yields of 80-97% after
46
47 recrystallisation from CHCl₃. All the compounds were characterised using conventional
48
49 methods (see experimental section). The sensors were partially soluble in CDCl₃, and fully
50
51 soluble in DMSO-*d*₆. In the latter solvent, two characteristic resonances were observed at 8.47
52
53 ppm and 8.45 ppm, for the urea protons of the electron deficient **3a**, while for the electron rich
54
55 sensor **3d** these protons appeared at 8.14 ppm and 6.61 ppm.
56
57
58
59
60

The X-ray crystal structure analysis of [2+2] photochemical adduct of **3b**

Several attempts were made to obtain crystals of the above sensors for X-ray crystal structure analysis. However, the use of slow evaporation or diffusion techniques failed on all occasions. In contrast, colourless crystals were obtained from an NMR sample of **3b**, in DMSO-*d*₆, and were found to be suitable for X-ray crystal structure analysis.[23,24] Although, to our

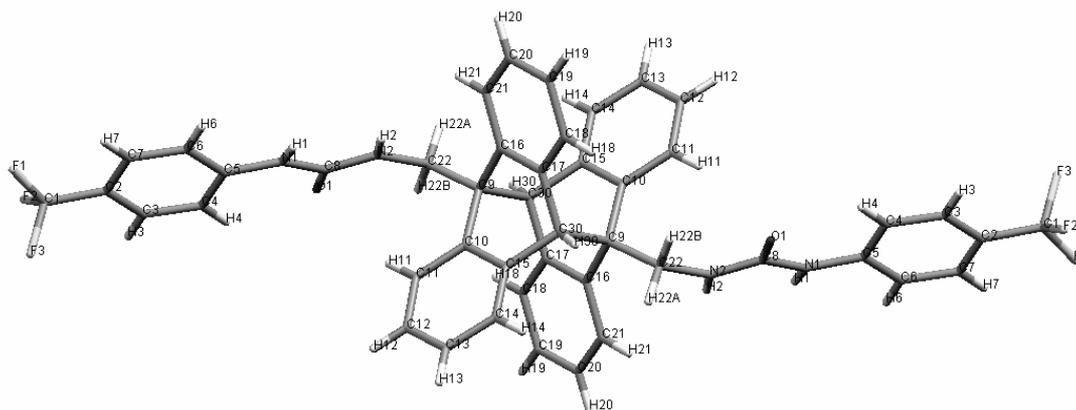

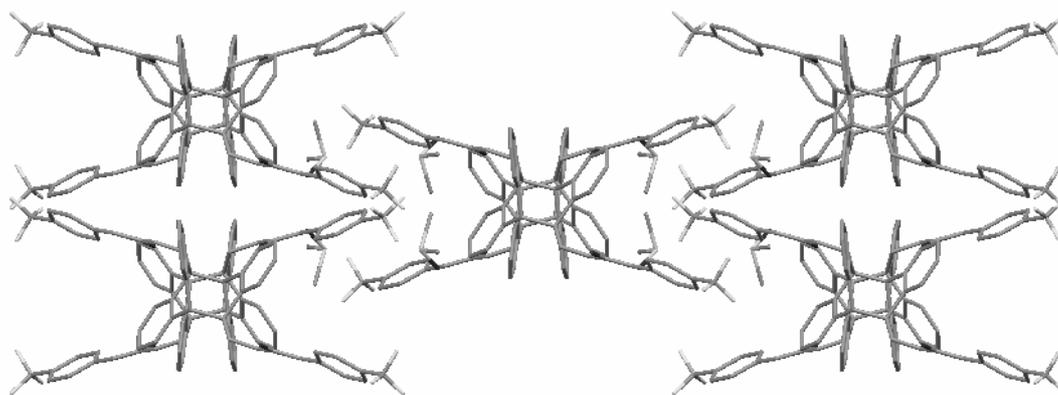

Figure 1. The X-ray crystal structure of the [4 π +4 π] cycloaddition product **4**, formed from **3b**. A DMSO molecule has been removed for clarity (see text).

surprise, the structure was not that of the desired sensor **3b**, but the product of the resulting [4 π +4 π] photocycloaddition dimerization reaction between two molecules of **3b**, *i.e.* **4**. The new bonds were formed between the central rings on each anthracene unit as is evident from Figure 1. It also shows that the structure adopts C₂ symmetry with the two urea receptors being *anti* to each other, with a single DMSO molecule being found in the unit cell. This structure can only be obtained photochemically, which is however, thermally reversible, and only from the desired compound **3b**. Hence, **4** can be viewed as being the proof of the formation of **3b**. This photochemical reaction is a common phenomenon for anthracene, which can be dimerized easily upon UV radiation.[25,26] However, the sample that these crystals were grown from was only exposed to halogen based room-light and/or sunlight. We therefore propose that the urea receptor activates the 9 position of the anthracene sensor **3b** in such a way that it dimerizes in this manner. The structure of **4**, is one of two possible structural isomers; the other being where the two receptors would be on the same side ('*syn*'

1
2
3 to each other) of the photodimerised product of **3b**. This is also known as the *head-to-tail*
4 product.[25,26] Compound **4**, is however, the so called tail-to-tail product, and is described as
5
6 being the more stable of the two isomers. It is usually the product isolated upon
7
8 photodimerization of such 9-substituted anthracene molecules. This is also believed to be the
9
10 more thermally reversible product. As is typical for such dimerization products, the four aryl
11
12 rings adopt a double wing like appearance, with a C...C bond length of 1.626(4) Å between
13
14 the two former anthracene 9 and 10 positions. Moreover, the bond angle between the C9-C30-
15
16 C17 atoms was found to be on average 113.1°, which is also typical for such products. The
17
18 structure also shows that the urea moieties are almost coplanar with the 4-(trifluoromethyl)
19
20 phenyl groups, with average N...H bond length of 0.860Å.
21
22
23
24
25

26
27 The packing diagram of **4** viewed down the crystallographic c axes can be seen in
28
29 Figure 2. This shows that each of the urea moieties is hydrogen bonded to the oxygen of an
30
31 aforementioned DMSO molecule, with a O...H bond length of 2.95 Å. However, even
32
33
34

35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51 **Figure 2.** The packing diagram for **4** by viewing down the c-axis. Hydrogen atoms and
52 short-contacts have been removed for clarity.

53
54 though the 4-(trifluoromethyl) phenyl groups show evidence of stacking, the distance between
55
56 the two aryl groups is 8.7Å, which is too long to account for any π - π stacking interactions.
57
58 There is however, a further F...H interaction between the aryl CF₃ groups and the protons of
59
60

1
2
3 the DMSO molecules with average F...H distance of 2.66 Å. The anion recognition ability of
4
5 this structure was not evaluated.
6
7
8
9

10 Photophysical evaluation of 3a-3d

11
12 The photophysical properties of the four sensors were evaluated in DMSO. The ground state
13
14 properties of **3a-3d** were first investigated. The absorption spectra of all the sensors were
15
16 almost identical, when recorded in DMSO, with bands appearing at 340, 369 and 324 nm,
17
18 respectively, and a shoulder at 333 nm which was assigned to the aryl groups of the receptor
19
20 moieties. These are significantly shifted towards the red in comparison with anthracene,
21
22 which has three characteristic bands appearing at 342, 360 and 380 nm, respectively.[27] For
23
24 these four sensors, extinction coefficients of 9920, 10830, 7279 and 9560 [Mol⁻¹cm⁻¹] were
25
26 determined in DMSO for **3a-3d**, respectively.
27
28
29
30

31
32 Using for excitation, the 369 nm transition of the anthracene based sensors, and the
33
34 360 nm band of the reference anthracene chromophore, the fluorescence emission spectra
35
36 were recorded in DMSO. Here, the characteristic fluorescence emission of the anthracene
37
38 fluorophore was observed for all the compounds, with that of the sensors being red-shifted by
39
40
41
42

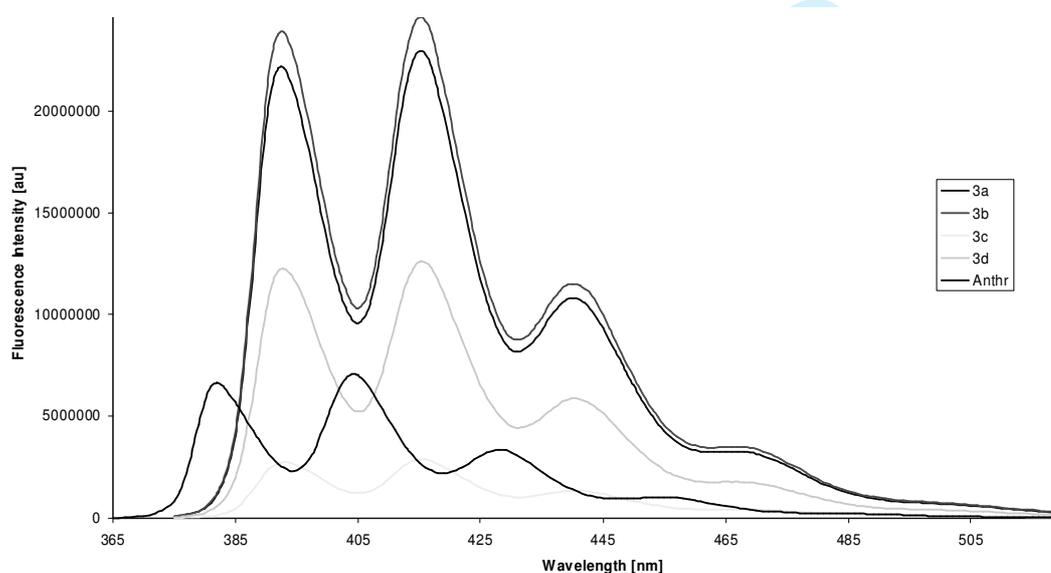

Figure 3. Comparison between the fluorescence emission spectra of chemosensors **3a-d** and the spectrum of anthracene, **Anthr**, in DMSO.

1
2
3 *ca.* 10 nm in comparison with that of anthracene itself, Figure 3, emitting at 393, 415 and 440
4 nm, with a shoulder at 466 nm. As can be seen from Figure 3, the intensity of all the sensors,
5
6 with the exception of **3c**, was greater than that of the reference anthracene compound. For **3a-**
7
8
9
10 **3d** the quantum yields of fluorescence (Φ_F) were determined as 0.53, 0.57, 0.06 and 0.33,
11
12 respectively under these experimental conditions, where the order is **3a>3b>3d>3c**, which
13
14 shows that the more electron withdrawing substituents give rise to the higher quantum yields.
15
16 This follows a known trend, where 9,10-dimethyl anthracene has a higher quantum yield than
17
18 9-methyl-anthracene, which subsequently has higher quantum yield than anthracene itself.
19
20 However, and perhaps somewhat surprising, then it is worth noting that in the case of **3c**, the
21
22 di-substitution at the aryl ring gives rise to a very low quantum yield in comparison the rest of
23
24 the sensors. A similar trend was seen for the fluorescence lifetimes (τ_F) in DMSO. The decays
25
26 upon excitation of the 356 nm transition and observation at 450 nm were all single
27
28 exponential, and had lifetimes 7.83, 8.99, 1.32 and 4.96 ns, respectively for the sensors **3a-3d**.
29
30 From these changes, the rate constants for fluorescence k_F , can be determined, as being
31
32 6.76×10^7 , 6.34×10^7 , 4.55×10^7 and $6.67 \times 10^7 \text{ s}^{-1}$ for **3a-3d**, respectively. From these results it is
33
34 clear, that even though there is no significant difference in either the λ_{Absmax} or λ_{Fmax} for these
35
36 sensors, the anion urea receptors have a significant effect on both Φ_F and τ_F . This is most
37
38 pronounced for the electron rich reporter system **3c**, where Φ_F and τ_F are significantly lower
39
40 than that observed for the remaining sensors. This is most likely to be due to a more efficient
41
42 photoinduced electron transfer quenching of the anthracene excited state by **3c**, in its 'free'
43
44 form (in the absence of any anions), while the electron withdrawing substituents of **3a** and **3b**
45
46 make the aromatic urea electron deficient and hence less able to participate in PET quenching.
47
48 This is supported by the fact that the results obtained for sensor **3d**, follow this trend, where
49
50 both the Φ_F and τ_F are smaller than that of **3a** and **3b**, but larger than that of **3c**. It is also
51
52
53
54
55
56
57
58
59
60

worth noting that **3a** and **3b**, which have electron withdrawing substituents on their receptors, seem to have very similar photophysical properties.

Anion binding evaluations of compounds **3a-3d**

Having established the fundamental photophysical properties of compounds **3a-3d**, the four compounds synthesised above were evaluated for their ability to detect anions in DMSO, by observing the changes in both the absorption and fluorescence emission spectra upon titrating these sensors with stock solutions of AcO^- , H_2PO_4^- , F^- , Cl^- , Br^- and I^- (as their tetrabutyl ammonium salts). Upon titration of these sensors with anions such as AcO^- , H_2PO_4^- , F^- , only minor changes were seen in the absorption spectra for the anthracene component at longer wavelengths, while more significant changes were seen at shorter wavelengths. While

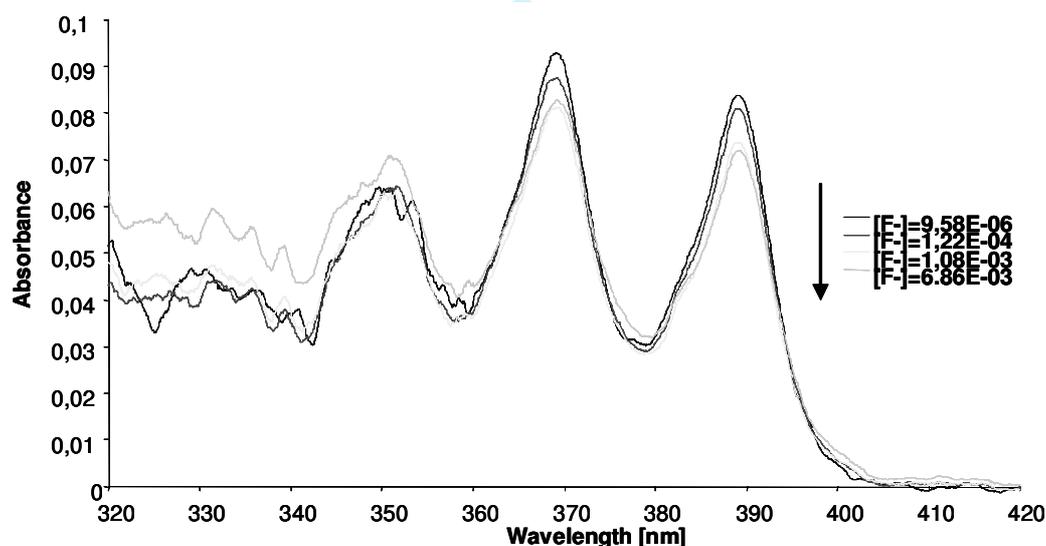

Figure 4. The changes in the absorption spectra of **3a** upon titration with F^- upon excitation of 369 nm, in DMSO.

these latter changes were assigned to the interaction of the anion at the urea receptor, the lack of changes in the anthracene transitions is not all together surprising as the methylene spacer should prevent any significant ground state interactions between the two parts. This is clear from Figure 4 which shows the titration of **3a** with F^- , where the major changes in the

absorption spectra occur at short wavelengths, indicating direct interaction between the receptor and the anion through hydrogen bonding.

Similar results were observed for H_2PO_4^- . When these measurements were made using AcO^- the changes in the shorter wavelengths were more pronounced. In comparison to these changes, the absorption spectra of **3a-3d** were not affected by the addition of either Cl^- or Br^- . However, upon titration of these sensors with I^- no significant changes were observed in the absorption spectra at low and medium concentrations ($0 \rightarrow 3 \text{ mM}$), while at high concentrations ($\sim 0.02\text{M}$) the fine structure of the absorption spectra was displaced by an intense, broad structure, signifying strong ground state interactions between these sensors and I^- under these conditions. In general, the changes in the absorption spectra of the fluorophore, with the exception of I^- can be considered to be minor and only the changes at short wavelengths, assigned to that of the receptor are affected. This indicates that anions such as AcO^- , H_2PO_4^- , F^- only interact with the receptor part of the sensors and that the methylene spacer prevents any ground state interactions between the fluorophore and the receptor.

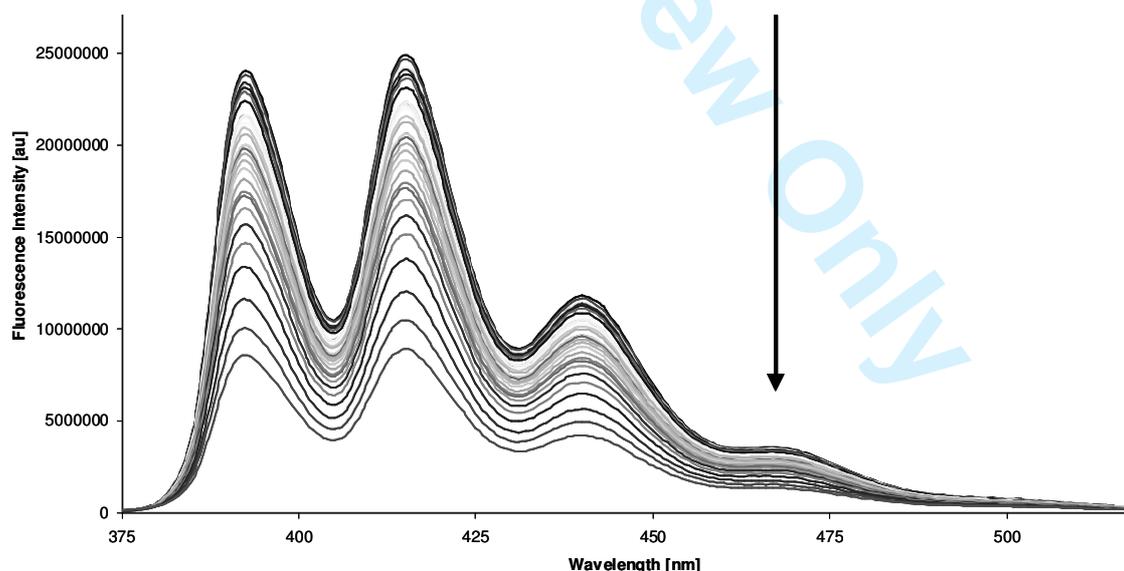

Figure 5. Fluorescence emission of **3a** titrated with TBAAcO, from top to bottom $[\text{AcO}^-] = 0$ to $6.27 \times 10^{-2} \text{ M}$. From values of the fluorescence intensity at 415nm the value for the quenching extent was measured to be *ca.* 64%.

1
2
3 Hence, it can be concluded that these urea based sensors behave as 'ideal' PET sensors for
4
5 anions.
6

7
8 In contrast to the changes in the absorption spectra, the anthracene based emission was
9
10 significantly modulated upon titration with the above anions in DMSO. The changes observed
11
12 for the titration of **3a** with AcO^- , is shown in Figures 5. It clearly demonstrates that the
13
14 emission is quenched upon addition of AcO^- , signifying the recognition of the anion at the
15
16 receptor side. It is also noticeable, that only the intensity of fluorescence is modulated and no
17
18 significant changes are observed in the positions of the three characteristic anthracene
19
20 emission bands. It can thus be concluded that these sensors behave as PET sensors, where the
21
22 emission of the fluorophore is quenched by PET from the receptor to the excited state of the
23
24 fluorophore.
25
26
27

28
29 Unlike that observed for classical PET cation sensors, where the emission is enhanced
30
31 due to the suppression of PET, caused by the increased oxidation potential of the receptor
32
33 upon cation recognition, the emission here is reduced. This can be viewed as a result of the
34
35 formation of a more electron rich anion-receptor complex, which gives rise to the
36
37 enhancement of the reduction potential. As Figure 5 demonstrates, the changes in the
38
39 emission spectra were homogenous across all the wavelengths, *i.e.* no particular transition was
40
41 more reduced than the other. Consequently, by observing the changes in the 414 nm transition
42
43 as a function of $\log[\text{AcO}^-]$, a sigmoidal plot was obtained, from which a binding constant \log
44
45 β was determined to be *ca.* 2. By plotting $\text{Log} [(I_{\text{max}}-I_{\text{F}})/(I_{\text{F}}-I_{\text{min}})]$ as a function of $\log[\text{AcO}^-]$,
46
47 a linear plot ($R^2 = 0.92$) was observed from which a $\log \beta = 2.14 (\pm 0.1)$ was determined.[28]
48
49
50 This indicates a weak binding between the sensor and the anion. When the same titrations
51
52 were carried out using **3b-3d**, similar luminescent changes were observed, where the emission
53
54 was quenched upon increasing anion concentration, without any measurable changes in λ_{max} .
55
56
57 From these changes, binding constants of $2.44(\pm 0.1)$, $2.07(\pm 0.1)$ and $2.09(\pm 0.1)$ were
58
59
60

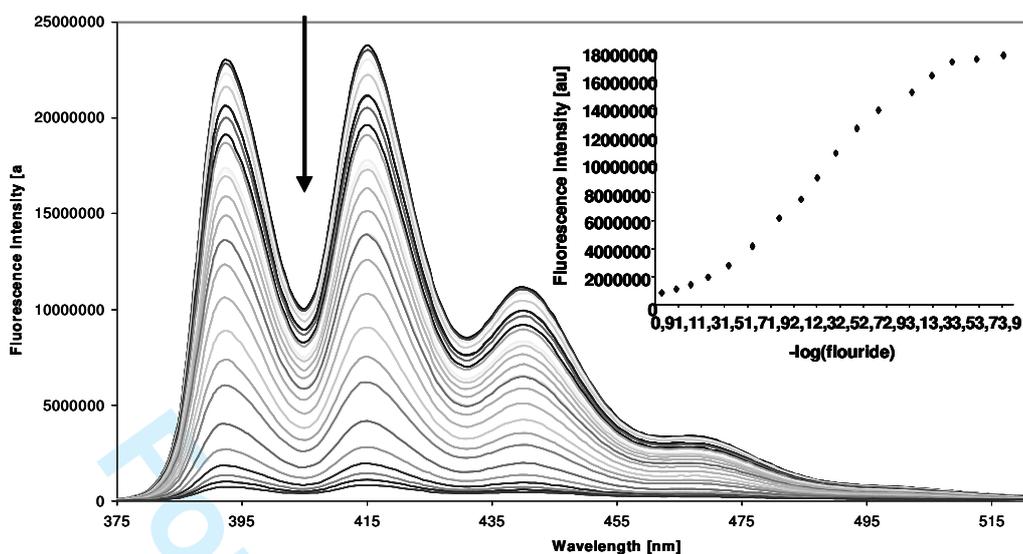

Figure 6. Fluorescence titration spectra showing the changes in fluorescence emission of **3a** in DMSO upon addition of fluoride, from top to bottom, $[F^-] = 0 \rightarrow 1.1 \times 10^{-1}$ M. Insert: The changes in the 415 nm transition as a function of $[F^-]$.

determined, for **3b-3d**, respectively. However, for all of these the quenching was more efficient than seen for **3a**, being 81%, 70% and 83% for these three sensors, respectively. The effect of the substituent on the aryl urea receptor can also be seen from these changes. However, these are not as dramatic as one would anticipate. While the binding affinity follows the trend of **3b**>**3a**>**3c** ~**3d**, displaying a marginally stronger binding for the two electron deficient receptors, there is no significant difference in these values. Hence, while the electron withdrawing groups would be expected to make the urea protons more acidic and as such, better hydrogen receptor, the difference in the binding constants does not reflect this. When these titrations were repeated using $H_2PO_4^-$, similar effects were observed. However, the degree of quenching was less, being 50%, 65%, 60% and 57% for the four sensors, respectively. From these changes binding constants ($\log \beta$) of $1.91(\pm 0.1)$, $2.11(\pm 0.1)$, $1.90(\pm 0.1)$, and $1.96(\pm 0.1)$, were determined which follow the same trend as seen previously for acetate. When either Cl^- or Br^- were used, the emission was only partially quenched, and only at high concentrations. However, these changes were too small for accurate binding constant determination. We assign this quenching to the formation of a hydrogen bonding

1
2
3 complex between the anion and the receptor rather than being due to heavy atom affect
4
5 quenching.
6

7
8 The titration of **3a-3d**, using F^- gave similar luminescent changes, *e.g.* no spectral
9
10 shifts were observed and only the fluorescence emission was quenched, demonstrating
11
12 effective PET quenching from the receptor upon anion recognition. However, unlike that seen
13
14 above, the emission was almost fully quenched. This can be seen in Figure 6, for **3a**, which
15
16 shows that the anthracene emission is reduced by almost 90% at the end of the titration.
17
18 Similarly, the emission was quenched for **3b-3d**, where it was reduced by *ca.* 97%, 91% and
19
20 97%, respectively. From these changes, the binding constants $\log \beta$ of 2.73(± 0.1), 3.26(± 0.1),
21
22 2.59(± 0.1) and 2.99(± 0.1), were determined.
23
24
25
26

27 While the same trend is observed here as above, the binding constants as well as the
28
29 efficiency of the quenching are significantly higher than seen for either AcO^- or $H_2PO_4^-$. We
30
31 have previously postulated that this is due to two main phenomena. Firstly, the small ion has
32
33 higher charge density than either AcO^- or $H_2PO_4^-$ and can form stronger hydrogen bonding
34
35 complexes with the receptor. Secondly, F^- is a good base in DMSO.[27] Consequently, F^-
36
37 can possibly deprotonate the urea receptor. This, has been shown to occur through a two step
38
39 mechanism, which gives rise to the formation of bifluoride, HF_2^- , the formation of which can
40
41 be monitored by NMR.[29] Moreover, the formation of such species in anion complexes has
42
43 recently been demonstrated using X-ray crystallography.[30] This deprotonation results in the
44
45 formation of a highly electron rich receptor, which consequently is also a more efficient PET
46
47 quencher. It is also possible that the HF_2^- products form a very strong ground state complex
48
49 with the receptor. With the aim of firmly establishing the nature of the quenching, we decided
50
51 to determine the rate of the quenching process for all of the sensors using the aforementioned
52
53 anions.
54
55
56
57
58
59
60

Kinetics of fluorescence quenching

In order to obtain the quenching rate constants, k_q , from fluorescence intensity measurements at different anion concentrations, $[Q]$, the Stern-Volmer kinetics was followed, **Equation (1)**, where I_0 and I are the fluorescence emission in the absence of quencher (anion) and for a given concentration of anion $[Q]$, respectively, K_{sv} and k_q are the Stern-Volmer and quenching rate constants respectively ($K_{sv} = k_q \tau_0$) and τ_0 is the lifetime in the absence of quencher.[27] Here the plot of I_0/I versus the anion concentration should be linear with a slope equal to $k_q\tau_0$. In Figure 7, the results for the titration of **3a** with F^- are shown. A

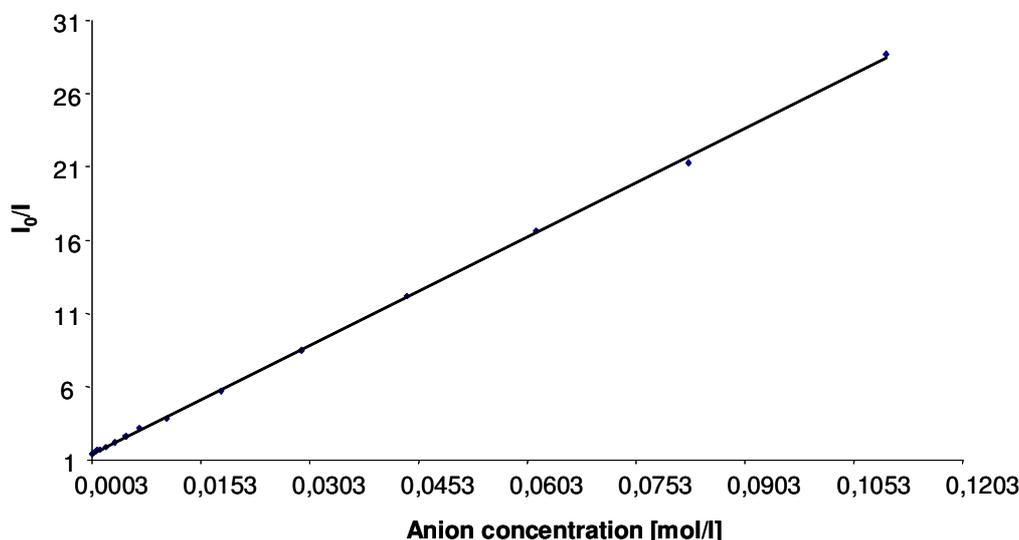

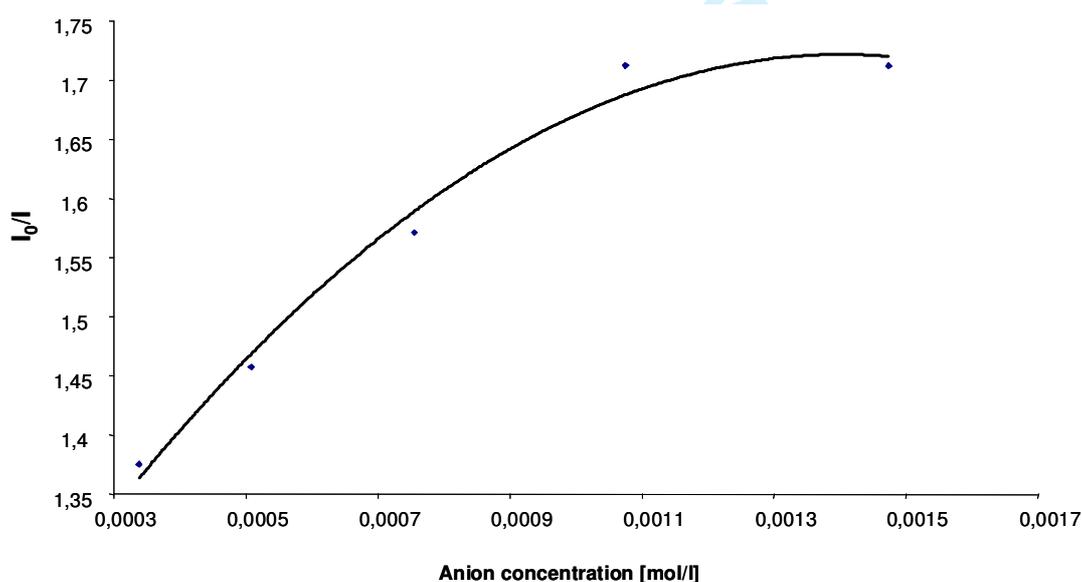

Figure 7. Stern-Volmer plot for the fluorescence quenching of **3a** by F^- . The solid line translates the theoretical curve from the Stern-Volmer **Equation (1)**. Quantitative analysis of the data, based on **Equation (1)**, yielded a Stern-Volmer constant, $K_{sv} = 246.68 \text{ M}^{-1}$. The fluorescence lifetime of **3a**, τ_0 , was previously determined as being 7.83 ns. Using this lifetime, the quenching constant was found to be $k_q = 3.15 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$. The good correlation coefficient obtained leads us to believe that, apparently, a linear behaviour was followed.

$$\frac{I_0}{I} = (1 + K_{sv}[Q]) = (1 + k_q \tau_0 [Q]) \quad (1)$$

1
2
3
4
5
6 However, a more detailed study of the Stern-Volmer plot shows that this linearity was not in
7
8 fact apparent at a low concentration of F^- . As can be seen in Figure 8, the linear behaviour of
9
10 the Stern-Volmer equation was not observed on the titration of **3a**. This observation can be
11
12 stated, not only to this experiment, but to all our other experiments. The deviation of the
13
14 Stern-Volmer equation from linearity can be explained if we consider an alternative
15
16 quenching process to the dynamic quenching. Hence, the quenching of the fluorescence
17
18 emission can also arise from static quenching, which can be considered to be due to the
19
20 interaction between the receptor and the sensor in the ground state, prior to excitation, or
21
22 dynamic quenching, with formation of a complex between the excited sensor, and the anion
23
24 receptor. Because of this, both the static and dynamic quenching effects were taken into
25
26 account in the modified Stern-Volmer equation, **Equation (2)**, where k_s is an equilibrium
27
28 constant for the static quenching. [31]
29
30
31
32

$$\frac{I_0}{I} = (1 + K_{SV}[Q])(1 + k_s[Q]) = 1 + (k_s + k_q\tau_0)[Q] + k_s k_q \tau_0 [Q]^2 \quad (2)$$

Figure 8. Fraction of the Stern-Volmer plot for the fluorescence quenching of **3a** upon anion, F^- , titration

Using this equation, the kinetics of the fluorescence quenching were re-fitted, by using τ_0 , 7.83×10^{-9} s and both the dynamic and static quenching constants, k_q and k_s , determined. For these changes, the values for k_q and k_s were found to be: $k_q = 3.09 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$, $k_s = 0.22 \text{ M}^{-1}$. Even though these are not very significant, from what we observed above, the results do suggest the presence of the static quenching which implies that the sensor is interacting with the anion both in the ground and excited state with a dynamic quenching rate constant close to the diffusion controlled values.

In order to differentiate the dynamic quenching constant obtained using **Equation (1)** from the one obtained using **Equation (2)**, the terms k_{qsv} and k_q were used respectively. The values of K_{sv} and consequently k_{qsv} (dynamic quenching constant based on $K_{sv} = k_{qsv} \tau_0$), k_q and k_s found for the fluorescence titrations of **3a-d** with F^- , I^- , AcO^- and $H_2PO_4^-$, following the same method, are summarised in **Table 1**. Since the lifetimes are not dependent on the static quenching, the fluorescence lifetimes shown in **Table 1** for **3a-3d** as a function of the anion concentrations have been measured and analysed according to the **Equation (3)**, where τ_0 and τ are respectively the lifetimes in the absence and presence of quencher (same as reported above).

$$\frac{\tau_0}{\tau} = 1 + k_q \tau_0 [Q] \quad (3)$$

Table 1. Results from the kinetic investigation for the anion induced quenching of **3a-3d**.

Sensor	τ_0 [ns]	Anion	K_{sv} [M^{-1}]	k_{qsv} [$\text{M}^{-1} \text{s}^{-1}$]	k_q [$\text{M}^{-1} \text{s}^{-1}$]	k_s [M^{-1}]

		<i>H</i> ₂ <i>PO</i> ₄ ⁻	24.94	5.03×10^9	9.8×10^9	7.89 *

K_{sv} and consequently k_{qsv} , k_q and k_s values found for the fluorescence titrations of **3a-d** with *F*⁻, *I*⁻, *AcO*⁻ and *H*₂*PO*₄⁻. *All these values were taken as module as the values were found, following the method described above, to be negative.

From the results in Table 1, it is clear that the fluoride anion gives rise to large K_{sv} , even though its value changes dramatically within this set of sensors. Moreover, these values are about an order of magnitude greater than diffusion control. This is, probably due to, and as discussed earlier, the fact that there is some degree of ion pairing of bifluoride with the receptor. With the exception of *I*⁻, which has significant ground state interactions with the fluorophores, the same order was observed (as expected) as above with *AcO*⁻ > *H*₂*PO*₄⁻. These results also show that the quenching is on all occasion fast and dominated by dynamic quenching, except at low concentrations.

CONCLUSION

We have synthesised several new simple fluorescent PET anion sensors, **3a-d**. These were characterised using conventional techniques as well as the crystal structure of the dimerized [4π+4π] photocycloaddition product of **3b**. These sensors display 'ideal' PET behaviour upon

1
2
3 anion recognition, since only the fluorescence emission is “switched off” in the presence of
4
5 H_2PO_4^- , AcO^- , and F^- in DMSO. Hence, the changes in the ground state were only minor and
6
7 occurred at short wavelengths, which we associate with the interactions of the anions with the
8
9 receptor, which modulates the receptors redox potential. These sensors also showed good
10
11 selectivity with AcO^- being recognised over H_2PO_4^- . Nevertheless, **3a-d** all showed higher
12
13 affinity and more efficient quenching for F^- . This is not all together surprising since fluoride
14
15 high charge density and small size enables it to form strong hydrogen bonds with the urea
16
17 receptor. Moreover, the anion can deprotonate the receptors, forming HF_2^- which makes the
18
19 receptor a significantly stronger electron donor and hence an efficient quencher. We also
20
21 observed significant changes for the titration of **1**. However, these were deemed to be mainly
22
23 due to ground state interactions between the sensor and the anion. The absorption spectra of
24
25 all the sensors were shifted to longer wavelengths in comparison to anthracene. Moreover, all
26
27 the sensors, with the exception of **3c**, gave rise to larger quantum yields of fluorescence, and
28
29 were also red shifted. A more detailed evaluation of the quenching process using the Stern-
30
31 Volmer equation showed that generally the expected linearity was upheld confirming
32
33 dynamic quenching. However, closer examination for all the anions showed that at lower
34
35 anion concentration, static quenching was also observed.

EXPERIMENTAL

General:

Reagents (obtained from Aldrich) and solvents were purified using standard techniques. Melting points were determined using a Gallenkamp melting point apparatus. Infrared spectra were recorded on a Mattson Genesis II FTIR spectrophotometer equipped with a Gateway 2000 4DX2-66 workstation. ^1H NMR spectra were recorded at 400 MHz using a Bruker Spectrospin DPX-400 instrument. ^{13}C NMR spectra were recorded at 100 MHz using a Bruker Spectrospin DPX-400 instrument.

Spectroscopic studies:

All measurements were made at room temperature. Fluorescence spectra were measured using a Jovin Ivon-Spex-Fluorolog 3-2.2; the excitation wavelength was 369 nm, the excitation and emission slit widths were 0.5 mm. Emission spectra were corrected for the instrumental response of the system. The absorption spectra were recorded on a Shimadzu UV-2100 spectrophotometer. All absorption and fluorescence spectra were obtained from a solution of the sensor in DMSO in both the absence and the presence of anion guests. The effect of anions on the sensors was investigated by addition of different volumes of an anion (Br^- , Cl^- , I^- , F^- , AcO^- , H_2PO_4^-) solution in DMSO, with different concentrations (10^{-5}M to 1M), to a 2ml solution of **3a-d** in DMSO. In each case, for the fluorescence spectra, additions were accompanied with magnetic stirring. All titrations were repeated two times to ensure reproducibility. All the anions were used in the form of their tetrabutylammonium salts [(TBA), $(\text{C}_4\text{H}_9)_4\text{N}^+$]. These salts were purchased from Aldrich and used without further purification. DMSO was purchased from Riedel-Häen and stored over molecular sieves prior to use.

1
2
3 Fluorescence decay measurements were carried out using a home-built TCSPC apparatus with
4 an N₂ filled IBH 5000 coaxial flash lamp as excitation source, Jobin-Ivon monochromators,
5
6
7
8 Philips XP2020Q photomultiplier, and Canberra instruments TAC and MCA. [32, 33]
9
10 Alternate measurements (1000 c.p.c.) of the pulse profile at 356 nm and the sample emission
11
12 were performed until 1-2 × 10⁴ counts at the maximum were reached. The fluorescence
13
14 decays were analyzed using the modulating functions method of Striker with automatic
15
16 correction for the photomultiplier “wavelength shift” [34]. The method used to determine the
17
18 fluorescence quantum yields of compounds **3a-d** (Φ_F^C) involve a connection between the
19
20 fluorescence quantum yield of a reference (Φ_F^{ref}) and Φ_F^C . Anthracene was the reference used
21
22 ($\Phi_F^{\text{ref}} = 0.27$, in ethanol (EtOH), [35]). Firstly absorbance of the reference, in EtOH, and
23
24 compounds, in DMSO, were adjusted to similar values (below 0.10) at the excitation
25
26 wavelength. After this, the fluorescence spectra were recorded, under identical experimental
27
28 conditions, and a comparison was made between the integrated areas under the fluorescence
29
30 spectra of both the reference and the compounds. At last the **Equation (4)** was followed in
31
32 order to obtain the Φ_F^C values [35], where A_{ref} and A_C are respectively the

$$\Phi_F^C = [(A_{\text{ref}} F_C n_C^2) / (A_C F_{\text{ref}} n_{\text{ref}}^2)] \Phi_F^{\text{ref}} \quad (4)$$

absorbance of reference and compounds at the excitation wavelength, F_C is the integrated
emission area of the compounds ($\int I(\lambda)^C d\lambda$) and F_{ref} is the integrated emission area of the
reference spectra ($\int I(\lambda)^{\text{ref}} d\lambda$), n_C and n_{ref} are respectively the refraction index of the solvent
containing the compound (DMSO), $n_{\text{DMSO}} = 1.4793$ and the reference (EtOH), $n_{\text{DMSO}} = 1.3611$.

[27]

Synthesis:

1
2
3 9-Aminomethyl anthracene, **1** (0.1 g, 4.83×10^{-4} mol) was dissolved in ca. 5 mL of freshly
4 distilled dry CH_2Cl_2 . To this solution 1.1 equivalent of the appropriate isocyanate in a single
5 portion was added. Off-white or light yellow precipitates were immediately formed upon
6 addition of the isocyanate. The reaction was allowed to stir for several hours, before the
7 precipitate was isolated by filtration, washed with dry CH_2Cl_2 and dried under high vacuum
8 (over P_2O_5) and eventually recrystallised from CHCl_3 to give powders.

20
21
22 [23] The data were collected on a Bruker Smart Apex Diffractometer*. The crystal was
23
24 mounted on 0.35mm quartz fibre and immediately placed on the goniometer head in a 123K
25
26 N₂ gas stream. The data was acquired using Smart Version 5.625 software in multi-run mode
27
28 and 2400 frames in total, at 0.3° per frame, were collected. Data integration and reduction was
29
30 carried out using Bruker Saint+ Version 6.45 software and corrected for absorption and
31
32 polarization effects using Sadabs Version 2.10 software. Space group determination, structure
33
34 solution and refinement were obtained using Bruker Shelxtl Ver. 6.14 software. SMART
