36 **ABSTRACT**
37

38 This article examines the relevance of the concept of multi-level governance for
39 understanding changes in science policy in France. It explores the emergence of a pattern of
40 multi-level governance, particularly in relation to arenas for negotiation between national and
41 multi-level governance, particularly in relation to arenas for negotiation between national and
42 regional levels. Compromises are made between the principles of competition and equality
43 and there is great diversity across regions in terms of the capacities for developing bottom-up
44 strategies for science-based development. The article highlights the prerequisites for the
45 development of a multi-level polity and emphasises the continued role that central
46 government retains in the global design of science policy.

INTRODUCTION

It is widely acknowledged that the sovereignty of the nation-state has been eroded. Commentators have focussed on globalisation and internationalisation as indicative of shifts in supra-national governance, while others have emphasised the importance of sub-national actors and the rise of the 'region state' (OHMAE 1993). Attention has been drawn to changing notions of governance in terms of the involvement of non-state actors, as much as the reallocation of decisional responsibilities between tiers of government. Multi-level governance rejects an either/or approach and focuses on the subtle processes through which supra-national and sub-national governmental and non-governmental agencies are encroaching on traditionally centralised policy areas (MARKS 1993. BACHE AND FLINDERS 2004).

The case of science policy offers a fertile arena for examination of multi-level governance dynamics. Within Europe, for instance, the European Research Area (ERA) initiative or the development of a European Research Council (ERC) indicate a strengthening supra-national tier of governance. This has been accompanied by the emergence of regional science policies as elected regional governments, development agencies and city partners attach increasing importance to science as a tool in economic growth. The distinction between science policy and innovation policy is important here. Whilst regional authorities have long engaged in innovation activities, particularly those aimed at SMEs (CHABBAL 1995), regional policy makers have shown reluctance to fund scientific activities or institutions. Throughout the 2000s, however, the frontiers between science and innovation policies have become blurred, due to the increasing relationship between science and wealth creation, the changing nature of relevant science and technology (S&T) fields and the new constraints of public finance that have led to increased co-funding schemes. Such changes have brought new actors into the science and innovation policy field, among them regional governments and agencies,

1
2
3 but also non-state actors, reflecting both vertical and horizontal shifts in science policy
4
5 governance.
6

7
8 This article assesses the relevance of the concept of multi-level governance in science
9
10 policy in France. The French case provides unique insights to the challenges of multi-level
11
12 governance in a country with a long-standing tradition of centralist administration and a
13
14 strong attachment to the principles of equality and balanced growth. The French regions have
15
16 traditionally had no official competence in the management and organisation of the research
17
18 system and have generally been considered as a weak level of government in relation to their
19
20 international comparators (LE GALES and LEQUESNE, 1998). In the last years, however,
21
22 regions have emerged as intermediate actors in complex governance structures and spaces for
23
24 the negotiation of science policy between national and regional actors have been created. Yet
25
26 the pattern of regional involvement in science policy is not even; considerable diversity and
27
28 variability can be seen, reflecting new compromises between the principles of competition
29
30 and equality.
31
32
33
34
35

36 This article reflects recent research activities (2004-2006) on regional and local
37
38 science-based growth in Europe, funded by the European Commission and the UK's
39
40 Economic and Social Research Council.¹ The research has included interviews at national
41
42 and regional levels, extensive documentary analysis and the collation of data on French
43
44 regions through national ministry sources and national evaluations. The paper is organised in
45
46 three sections. First, we begin by reviewing the literature on multi-level governance and the
47
48 challenges that a multi-level, multi-actor science policy system poses to the French State. The
49
50 second section considers the empirical material in terms of an enlarged regional dimension to
51
52 national science and innovation policy; arenas for negotiation and the capacities of regions to

9

10 *Identifying multi-level governance*

11

12
13 The increasing complexity of governance structures can be seen as both a response to
14
15 the crisis of legitimacy of the State and to greater demands for democracy (KOOIMAN, 1990).
16
17 Authors have emphasised the weakness of the state due to fiscal crisis, decentralisation and
18
19 administrative reforms and the introduction of new forms of public management as bringing
20
21 about a wider shift from government to governance (PETERS and PIERRE, 2001). Problem-
22
23 solving is no longer seen as necessarily corresponding to one authority or to a specific
24
25 institutional territory. Instead, governance can refer to institutions and actors drawn from and
26
27 beyond government; the blurring of boundaries and responsibilities for tackling social and
28
29 economic issues; autonomous self-governing networks of actors; and the capacity for
30
31 government to use new tools and techniques to steer and guide policy (STOKER 1998). Such
32
33 propositions draw attention to the multiplicity of authorities and agencies involved in policy
34
35 and employing a variety of techniques and forms of knowledge (DEAN, 1999).
36
37
38
39
40

41
42 Multi-level governance appears as a useful tool to capture these processes and describe
43
44 evolving political systems, referring to the "the dispersion of central government authority
45
46 both vertically to actors located at other territorial levels, and horizontally, to non state-actors"
47
48 (BACHE AND FLINDERS 2004 : 4). It presupposes that authority is polycentric, shared between
49
50 multiple actors, territorial levels and with each level disposing of specific resources
51
52 (CONZELMANN 1998. BENZ AND EBERLEIN 1999). Negotiation, non-hierarchical exchanges
53
54 between levels of government and horizontal relationships at each scale of government are
55
56 seen to be important features (PETERS AND PIERRE 2001). Yet criticisms have focused on its
57
58
59
60

1
2
3 lack of robustness as an analytical term (JORDAN, 2001) and difficulties in its
4
5 operationalisation.
6
7

8 In an attempt to address these concerns, HOOGHE and MARKS (2003) distinguish
9
10 between two types of multi-level governance: type I and type II where the former is based on
11
12 federalism and the latter a more variable geometry of organisation. Type I consists of power
13
14 sharing between a few levels, non-intersecting governments in limited areas and stable
15
16 authority. Type II is defined by many jurisdictions, which are task specific, intersecting and
17
18 more flexible. Yet within this typology multi-level governance remains defined as a
19
20 normative concept rather than an analytical tool. Acknowledging different types of multi-level
21
22 governance does not necessarily enable the initial identification of a multi-level polity.
23
24
25
26

27 What then are the critical tests that indicate the extent and nature of the dispersion of
28
29 state authority and the identification of multi-level governance? Decentralisation and
30
31 processes of European integration have created a system of exchanges between different
32
33 territorial levels such that relations are no longer state-centred. The emergence of
34
35 relationships between institutions at different levels implies negotiation and dialogue, rather
36
37 than hierarchical command and control relations. However, while actors, arenas and
38
39 institutions are not ordered hierarchically, the questions of authority and the asymmetry of
40
41 power have not totally disappeared. There is no necessary equality between institutions and
42
43 some actors are more powerful than others. In multi-level governance theories, this is
44
45 particularly the case in relation to national governments which can exploit new governance
46
47 structures to increase their steering capacity. Similarly, it has been noted that the role of sub-
48
49 national authorities has been overemphasised in multi-level governance analyses (JORDAN
50
51 2001). What is at stake therefore is the nature of exchanges, distribution and management of
52
53 resources and the relations between actors within each level of government. Arenas of
54
55 negotiation and trade-offs, bargaining and potential conflicts between levels all illustrate the
56
57
58
59
60

1
2
3 dynamics of multi-level governance in action. In addition, the capacity to take action becomes
4 important as do mechanisms to coordinate public action (PETERS and PIERRE, 2001). On this
5 basis, three criteria for operationalising multi-governance in any given policy area emerge: 1)
6 the relative roles and responsibilities of territorial actors, with a diluted (albeit dominant) role
7 for the central state 2) the existence and operation of arenas for negotiation and bargaining
8 between national and regional actors in the definition of priorities and allocation of resources
9 and 3) the capacities of different sub-national actors to exploit nationally-created
10 opportunities and / or develop policy from the bottom-up. We shall return to these three tests
11 later.

24 *National and Sectoral Diversity: Science Policy in France*

25
26
27 Multi-level governance has not been applied systematically across national settings or
28 policy arenas. Country variables such as national politico-institutional settings, national policy
29 styles and pre-existing institutionalised patterns of centre-periphery relations exert a strong
30 influence on the extent of multi-level governance. (CONZELMANN, 1995. JOHN 1996). Some
31 commentators have suggested that multi-level governance is a phenomenon which is
32 structurally restricted to decentralised member states (JEFFREY, 1996, p.201). France has
33 traditionally been seen as the archetype of a centralised country, yet processes of
34 decentralisation over the last two decades have reshaped the pattern of centre-periphery
35 relations (THOENIG, 2005). 'Co-administration' increasingly characterises relations between
36 the state and local authorities (REIGNER 2001) yet the identification of actors is problematic in
37 terms of the identification of appropriate levels of analysis (MCALEAVY AND DE RYNCK
38 1997. KEATING 1998). In France, as elsewhere, the notion of the 'region' can be
39 disaggregated, composed of several sub-national levels: conseils régionaux, conseils généraux
40 and communes. This only increases the potential actors and lines of authority that can
41 gradually erode centralised control.

1
2
3 Sectoral differences can also be observed (JORDAN 2001. PETERS AND PIERRE 2004).
4
5 Whilst originally applied to regional policy in the EU, the environment (FAIRBRASS and
6
7 JORDAN, 2004) or economic policy (PERRATON and WELLS, 2004) have also been subject to
8
9 analysis through the lens of multi-level governance. However, there has been little systematic
10
11 analysis of the shifting governance of science policy. Yet, recent developments around the
12
13 construction of a European Research Area herald potentially significant changes in the
14
15 territorial organisation of the European research infrastructure (for a wider discussion see
16
17 EDLER, KUHLMANN AND BEHRENS 2003. BARRE et al, 1997). A corollary to supranational
18
19 developments is an emphasis on the involvement of regional authorities as a prerequisite for
20
21 achieving the Lisbon target of investing 3% of GDP in R&D by 2010 (EUROPEAN
22
23 COMMISSION, 2001). Some countries, of course, have a long history of regional involvement
24
25 in science policy: Germany (KAISER, 2003), the US and Spain (SANZ-MENEDEZ and CRUZ-
26
27 CASTRO, 2005) are key examples in light of their federal structures. The significant point is
28
29 that regional involvement in science and higher education can be witnessed as a more general
30
31 phenomenon, even in traditionally centralised countries such as the UK (see PERRY, THIS
32
33 ISSUE), Japan (see KITAGAWA, THIS ISSUE) or France.

34
35 The debate over multi-level governance in science also takes place in the context of
36
37 changing research regimes (GIBBONS et al., 1994) and increasing public debates over science
38
39 (NOWOTNY et al., 2001). The strategic nature of science (RIP 2002) and emphasis on
40
41 innovation further disaggregates this policy area in terms of the involvement of public and
42
43 private actors at multiple scales. The post-WWII 'Big Science' paradigm, based on the
44
45 industrialization of science, with laboratories organized like firms around large equipments
46
47 and international networks, has been replaced by a less centralised and more networked form
48
49 of research. Such networks have specific territorial dimensions (LAREDO 2003. COOKE AND
50
51 PICCALUGA 2006). However, the spatial benefits of scientific activities are not evenly spread.
52
53
54
55
56
57
58
59
60

1
2
3 As in Canada where ‘governance by networks’ is emerging as a popular form of policy
4 intervention (see SALAZAR AND HOLBROOK, THIS ISSUE), current EU science policy is
5 explicitly designed to network centres of excellence between regions in different European
6 countries. Attention has already been drawn to the potential conflict between European
7 policies aimed at competition and cohesion and the current emphasis on concentration of
8 scientific resources, building economies of scale and networks of excellence will only
9 exacerbate this situation (SHARP, 1998. HERAUD, 2003). This raises key issues relating to the
10 distribution of the scientific and technological expertise on which economic development is
11 predicated and questions over the appropriateness of different scales for action.
12
13
14
15
16
17
18
19
20
21
22
23

24 The French case is interesting precisely because a decentralised and yet spatially
25 concentrated science policy is anathema to the principles on which the French State is based.
26 The principle of equality, ‘égalité’, enshrined since the French revolution, has been
27 traditionally interpreted as necessitating a direct and unmediated relationship between the
28 institutions of the French state and each individual citizen, as well as a commitment to
29 balanced growth and regional symmetry. The concept of multi-level governance in science
30 challenges these principles directly through presupposing multiple sources of authority and a
31 decentralised State, as well as the concentration of scientific resources in particular regions.
32 Moreover, for a long time, the French system of research and innovation was said to be
33 “colbertist” (CHESNAIS, 1993). The colbertist system was based on the involvement of the
34 State in science and technology, within a triangle of State, academic research, and industry.
35 However, this model is no longer relevant, as MUSTAR and LAREDO (2002) have shown, since
36 the French system has considerably evolved in the last twenty years. This has largely been
37 through spontaneous or opportunistic moves than through deliberate strategy. Yet the end of
38 ‘colbertism’ is not the end of State intervention (LANCIANO-MORANDAT and VERDIER 2004).
39 New forms of state intervention have emerged in the context of the drive for excellence,

6
7

8 **THE EVIDENCE: APPLYING THE THREE TESTS**

9 *A Regional Dimension to French Research and Higher Education Policy*

10
11
12 Throughout the 2000s, France's productivity gap in research and innovation has been
13
14 widely acknowledged. Relatively high levels of investment in public sector R&D, relative to
15
16 the UK for instance, have not translated into volumes of research outputs, leading to an
17
18 efficiency dilemma. Public sector research has not been matched by business expenditure on
19
20 R&D (BERD) and exploitation has been poor (MINISTERE DELEGUE A LA RECHERCHE ET AUX
21
22 NOUVELLES TECHNOLOGIES 2003). The blame for such inefficiencies has been consistently
23
24 placed on a vast and ossified public science and research system, with recurrent and non-
25
26 competitive research funding, jobs for life, the absence of a culture of exploitation and a lack
27
28 of synergy between public research and industry.
29
30
31
32
33

34
35 The last two years have seen key reforms established to address these issues, with the
36
37 aim of developing an internationally competitive, economically responsive, efficient, well-
38
39 staffed, highly mobile and flexible higher education and research system. Mirroring shifts
40
41 elsewhere, such as Finland (SOTARAUTA AND KAUTONEN, THIS ISSUE, P.14), recent measures,
42
43 as summarised in Table 1, have introduced new principles into the French system, notably, the
44
45 capacity for greater strategic planning and steering in science policy; a shift towards a culture
46
47 of projects, evaluated on transparent criteria rather than guaranteed recurrent funding for
48
49 research; and an increased focus on industry-research interactions as a basis for
50
51 competitiveness and wealth creation. The recent merger of the national Directorates for
52
53 Research and Technology to create a new Directorate for Research and Innovation can be
54
55 seen as indicative of this latter aim.
56
57
58
59
60

1
2
3 A feature of these reforms has been an increasing regional dimension to French
4 science and research. New forms of public intervention, budgetary constraints, particularly in
5 relation to university infrastructure, and the importance of the European project have
6 coincided to strengthen the regional dimension to science and research. A regional dimension
7 is also driven by the need to increase the efficiency of the research system and to maximise
8 economic returns from investments in R&D through spatial clustering and geographic
9 proximity.

10
11
12
13
14
15
16
17
18
19
20 New forms of public intervention have become dominant, with policy looking less
21 substantial and more procedural. While the state increasingly defines the rules of the game, it
22 does not specify implementation mechanisms leaving a vacuum between strategic direction
23 and necessary and available policy instruments. Increasingly, science policy is formulated
24 between top-down and bottom-up procedures. Decentralised actors, in particular regional
25 authorities, must respond to proposals and initiatives within a centrally designed framework,
26 corresponding to the type of public action that LANCIANO-MORANDAT and VERDIER (2004)
27 described as the model of "*Etat facilitateur*". This is a trend that can also be seen in other
28 European countries, such as Germany (KOSCHATZKY AND KROLL, THIS ISSUE). In the French
29 context, key examples include the *pôles de compétitivité* and the *réseaux thématiques de*
30 *recherche avancée* (RTRA). The *pôles de recherche et d'enseignement supérieur* (PRES)
31 represent a slightly different initiative in so far as these are bottom-up developments, not
32 subject to national competition and with no initial dedicated funding attached. The PRES are
33 largely academic collaborations and poorly connected to local actors. Yet despite significant
34 differences in the scale, scope, funding and governance of these initiatives (see Table 1), they
35 all represent varying attempts to bring combinations of academic, industry and local economic
36 actors together within geographically proximate spaces. The emphasis on clusters and
37 networks as tools for economic and scientific development builds on existing regional science
38
39
40
41
42
43
44
45
46
47
48

1
2
3 and innovation infrastructures. However, contrary to the English case, it is important to note
4
5 that the role of regional authorities has not been restricted to innovation activities; regions are
6
7 also now welcomed, should they so desire it, as partners in basic science and research as
8
9 much as exploitation.
10
11

12 INSERT TABLE 1 HERE
13
14

15 This is particularly relevant in the context of pressures on public spending in science
16
17 and the recognition by national actors that regional co-financing of science and technology is
18
19 necessary, if not desirable, for French competitiveness. Budgetary concerns have therefore
20
21 also diluted the capacity for central control over science, research and higher education.
22
23 Regional authorities were asked to work with the 6+9 world-class *pôles de compétitivité* to
24
25 help them develop bids for funding to the *Agence Nationale de Recherche (ANR)* and the
26
27 *Agence de l'Innovation Industrielle (AII)* and to give financial priority to those 38 clusters
28
29 which officially failed to get cluster status in their own spending plans. A recent assessment
30
31 of progress in the competitiveness clusters estimated regional co-funding at a level of €100m
32
33 (COMMUNICATION EN CONSEIL DES MINISTRES, 30 AUGUST 2006). As noted, above, the PRES
34
35 have no designated funding, yet the most successful will be able to apply for 4-year contracts
36
37 with the state, following a positive evaluation. Regional financial support may therefore be an
38
39 important precondition to generating the critical mass and local support necessary to pump-
40
41 prime potential national resource.
42
43
44
45
46
47

48 Financing higher education has been a key area in which regional authorities have
49
50 developed substantial roles, despite having no official competence in this area. Through the
51
52 programme called *Université 2000 (U2000)*, the state put in place a negotiation procedure in
53
54 order to involve regions in addressing the huge and rapid investment necessary in university
55
56 infrastructures (POUYET 1998). In exchange for regional money, the state was forced to
57
58 concede a role to sub-national authorities as partners in the policy-making process. Cities and
59
60

1
2
3 other sub-national authorities, as well as regional councils, have taken a lead in science and
4
5 technology policy, driven by the desire to host university or higher education training on their
6
7 territory. *Université du Troisième Millénaire* (U3M) was the second large planning operation
8
9 involving national and sub-national authorities in higher education. The novelty here was the
10
11 embedding of plans for medium-term academic infrastructures, through the *Contrats de Plan*
12
13 *Etat-Region* (CPER), within a longer-term foresight exercise with various regional actors.
14
15 University infrastructures have been a large part of the CPER, accounting for 11.5% of the
16
17 total allocations in the 2000-2006 planning phase (CIACT 2006). U2000 and U3M were
18
19 mainly top-down procedures and can be viewed as opportunistic instruments for financing
20
21 national policy in higher education. But, out of economic necessity, a small revolution
22
23 emerged leading to the lasting involvement of sub-national authorities in education and
24
25 science policy.
26
27
28
29
30

31
32 A third driver of an increasing regional dimension to higher education, science and
33
34 research is the development of the ERA. Within official documentation, France's active
35
36 support for the Lisbon challenge of raising R&D expenditure to 3% of GDP by 2010 is
37
38 evident and the Consultation on Research (2003) highlighted widespread support for *inter*
39
40 *alia*: integrating national research policy into a European perspective; bringing French
41
42 influence to bear on the ERA project; the creation of a European Research Council and a
43
44 better articulation between European research and university policy. In reality, while an
45
46 emphasis on centres of excellence can be seen, efforts to increase public and private R&D to
47
48 meet the 3% target have not taken centre stage.
49
50
51

52
53 The ERA project has specifically driven increased concern with efficiency,
54
55 competitiveness and international excellence in science. Yet regionalisation has also been an
56
57 important corollary to European developments and even a stepping stone to international
58
59 visibility and world-class excellence. For instance, the RTRA programme aims to encourage
60

1
2
3 the emergence of internationally excellent clusters of research, on the basis of the best French
4
5 research units, but sees geographic proximity as key to this aim. Similarly, the PRES aim for
6
7 international visibility through creating critical mass at the sub-national level. The resources
8
9 of regions to participate actively in these initiatives have been enhanced through the recent
10
11 decentralisation of European regional funds, as part of the reform of the CPER (see below).
12
13 French reforms are thus marked by a dualism between regional action and international
14
15 profile.
16
17
18

19
20 Recent shifts in French science, research and higher education clearly conceive a key
21
22 role for regional authorities, not only as financial contributors but as 'active' partners and
23
24 actors in their own right (see PERRY AND MAY, THIS ISSUE). However, the situation should not
25
26 be overestimated and a distinction needs to be made between limited devolution in relation to
27
28 framework policies and the organisations responsible for implementation. Indeed, public
29
30 research organisations and universities remain fundamentally state-controlled and managed
31
32 institutions with no necessary orientation towards regional or local needs. Universities are
33
34 increasing in importance in the French system and are now subject to a process of four-yearly
35
36 contract planning with the state (MUSSELIN 2001). Yet they remain relatively autonomous
37
38 public entities with the capacity to engage with regional actors, if not always the disposition.
39
40 It has been the subject of some debate as to whether regional authorities could be legitimate
41
42 partners or even signatories in university's contract planning. This has been resisted on the
43
44 part of some universities contradicting evidence of a 'regionalisation' of university activities
45
46 (GROSSETTI and LOSEGO 2003).
47
48
49
50
51
52

53 For their part, national research institutes, such as the *Centre National de la Recherche*
54
55 *Scientifique* (CNRS), have also started to reform their missions and organization with the aim
56
57 of joining up education, research and innovation and to improve the relationship with
58
59 universities in the context of increasing 'hybridisation' (MUSTAR and LAREDO 2002). Debates
60

1
2
3 have recently developed regarding a potential territorial dimension to this reform and the
4 possible reshaping of CNRS on an inter-regional level. Nevertheless, the decentralisation of
5 CNRS has had greater administrative significance than scientific. On the whole, the
6 orientation of research institutes has remained resolutely international and national. It remains
7 to be seen what the implications of new cluster and pole initiatives might be in altering the
8 geographical orientation of research actors.
9

10
11
12
13
14
15
16
17 The principle of regional equity, if not equality, has also shaped a distinctive French
18 response to the needs of a competitive international knowledge-based economy. Networks
19 and clusters of scientific excellence, rather than the concentration of resources per se, have
20 become preferred policy tools, demonstrating equality of opportunity to compete for science
21 resources, if not equality of outcome. This reflects a more gradual evolution in French policy
22 towards equity rather than equality as a precondition for competitiveness: ‘equity represents a
23 means of striving for equality within the reasonable limits of efficiency’ (BAUELLES and
24 PEYRONY 2005, 109). Baudelles and Peyrony note a changing regional development paradigm
25 in which competition between territories is no longer seen as a zero-sum game, a position
26 supported by the rejection of the notion of ‘compensatory solidarity’ by the most modern and
27 progressive localities (ibid 109).
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42

43
44 A good example of the distinctive French response to equality and competition – or
45 equity – is in the *pôles de compétitivité*. It was originally intended that there would be only
46 15 clusters selected, chosen on the basis of international excellence and visibility, partnership
47 and the capacity for innovation. This form of operation was clearly seen as a way to apply the
48 European approach of networking centres of excellence and is considered as a pathway
49 towards the implementation of the Lisbon strategy. In planning documents, the initiative was
50 conceived of an important tool of industrial policy, driven by a philosophy of ‘variable
51 geometry’ (CIADT 2004). However, a three-tier system of clusters has subsequently emerged
52
53
54
55
56
57
58
59
60

1
2
3 representing an attempted balance between competition and balanced growth. Of 105
4 applications, demonstrating the high degree of local interest in the concept, 67 clusters were
5 eventually funded (now 66 after some regrouping), with priority and preferential conditions
6 given to 6 world-class clusters and 9 second-tier clusters that might join the priority group
7 subject to reaching critical mass. The remaining successful clusters have been designated as
8 being of 'national status' and even those clusters that didn't make it into the 'top 67' have
9 €12m earmarked for their development. The geographical distribution of the clusters across
10 France is balanced, with each region participating in at least one cluster, thus highlighting the
11 real limits to French concentration (DATAR 2005). Compared with the UK context, for
12 instance, the location of national research institutes is also deemed a legitimate tool for
13 regional policy, such as in relation to the recent move of the *Institut national de recherche sur*
14 *les transports et leur sécurité (INRETS)* to Lyon-Bron (CIACT 2005) or the successful
15 application to host the International Thermonuclear Experimental Reactor (ITER) in
16 Caderache in Provence-Alpes-Côtes-d'Azur (PACA).

36 *Arenas for Negotiation and Contestation*

37
38 As with other European countries, the last two decades have seen an evolution of the
39 French administrative system towards greater devolution. What distinguishes the French
40 experience is the way in which *devolution* to sub-national public authorities - in terms of the
41 transfer of specific competencies - has been accompanied by the *decentralisation* of the
42 agencies of the central state.

43
44 Since the initial decentralisation laws of 1982, the varied sub-national levels – régions,
45 départements and communes - have emerged as increasingly significant actors mediating the
46 relationship between the state and its citizens. In 2003, legal changes strengthened processes
47 of devolution and enshrined the concept of a 'decentralised organisation for the French
48 Republic' within the constitution. Importantly, regions were made constitutionally equal with
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 other collectivities and given financial autonomy. In 2005, a second law further defined the
4 transfer of competences from the state to the collectivities, clarified responsibilities between
5 tiers and rationalised local and regional administration. Nevertheless, functional overlap
6 remains. Regional Councils have been given explicit responsibility for economic
7 development, yet other local authorities also have the right to intervene. Départements and
8 local authorities, and more recently *intercommunalités* (sets of communes regrouped for the
9 sake of specific projects) are now almost as active as regions in the economic field. This is an
10 important point to note, as it is via these economic development functions that sub-national
11 actors have increasingly encroached, from the bottom-up, on the traditionally centralised
12 policy domain of science, research and higher education.
13
14
15
16
17
18
19
20
21
22
23
24
25
26

27 Indeed, sub-national authorities have no constitutional rights to intervene in research
28 and higher education. Science policy is decentralised, through the functions of the Regional
29 Delegation for Research and Technology (DRRT), but not devolved. The DRRT is the
30 representative of national Government in the regions, akin to the English Government Offices
31 for the Regions, taking orders from the Ministry for Research. Yet it is generally considered
32 that the relative autonomy of the regional offices of national ministries and agencies (*services*
33 *déconcentrés de l'Etat*) is as important as the existence of devolved authorities for achieving
34 efficient regional governance. The expertise of such “decentralised” teams from the central
35 administration, as well as the room for manoeuvre vis-à-vis the Paris administration, are
36 judged as important success factors in the design of relevant regional policy.
37
38
39
40
41
42
43
44
45
46
47
48
49

50 The Republic, however, is decentralised but not federal. Regional autonomy is limited,
51 with variations between some ‘historical’ regions such as Bretagne (PASQUIER 2003) and
52 Alsace, and those regions without a strong cultural identity. Yet recently, limited flexibility
53 has been introduced through the notion of *le droit à l'expérimentation*. This established the
54 legality of implementing a devolved function in one (or more) region(s), as a means to ‘test’
55
56
57
58
59
60

1
2
3 an idea. It is consistent with COLE's (2006: 32) interpretation of decentralisation as a
4
5 mechanism to 'liberate the entrepreneurial energies and political capacity of local and
6
7 regional players'. However, the success of any experimental devolution is supposed to lead to
8
9 the general implementation of the initiative, regardless of the appetite of other regional
10
11 authorities. This acts as a strong constraint on devolution, since the unanimous willingness of
12
13 the French regions for greater autonomy cannot be assumed. In this respect, the 'right to
14
15 experimentation' is a good example of the balance between diversity and equality that
16
17 characterises the new French political philosophy. Nevertheless, it is an important innovation
18
19 in French policy. Firstly, national administration will be 'locked in' to changes through the
20
21 political difficulties of withdrawing any function from a region once it officially granted and
22
23 successfully trialled. Secondly, local decisions are increasingly being taken in the absence of
24
25 specific legal competence, science policy being a case in point, and such spontaneous
26
27 experiments may well be legalised after the fact. The experimentation right is important
28
29 therefore in creating potential gaps in central state control that can be exploited by sub-
30
31 national authorities to bring about multi-level governance from the bottom-up.
32
33
34
35
36
37

38
39 The primary arena for negotiation of national and regional interests in priority setting
40
41 and policy formulation in all areas of policy is the *Contrat de Plan Etat-Régions* (CPER). The
42
43 procedure was introduced in 1982 as a tool for integration between national and regional
44
45 plans and has subsequently replaced separate plans as the single multi-level negotiation about
46
47 public objectives, co-funding infrastructures and joint policies between central and regional
48
49 authorities. There have been four generations of CPER, the last between 2000-2006. Over this
50
51 period the amounts allocated by the state and regional authorities have tripled (INSTITUT
52
53 SUPÉRIEUR DES MÉTIERS 2006). In theory the contributions of the central state and regional
54
55 authorities are equal: in 2000-2006 the €38bn total allocations were made up of €19.5bn from
56
57 the state compared with €18.5bn by regional authorities, in addition to the mobilisation of
58
59
60

1
2
3 resources by other collectivities (CIACT 2006). Yet, as we discuss below, in practice the
4
5 balance is less clear, given that the State does not always deliver on its commitments leaving a
6
7 deficit to be filled by the regions.
8
9

10 The CPER cover all areas of public investments, including science and higher
11
12 education - to the extent that central and regional authorities have deemed this a priority in
13
14 different territories. As the regional role in science, research and HE has expanded, as detailed
15
16 above, so the importance of the CPER as an arena for negotiation in this domain has also
17
18 increased. Regional authorities, as well as departments and cities in certain cases, have
19
20 become real partners for science, innovation and higher education policy, negotiating their
21
22 own priority ranking against the central administration's policy for the territory (BARAIZE
23
24 1996). In the negotiation procedure, regional and national interests are compared, leading to
25
26 various tradeoffs under the general idea of global co-funding. Generally speaking, there are
27
28 few problems in reaching agreement for investments in areas where the region is obviously
29
30 leading. However, the increasing competition between regions in strategic areas such as S&T
31
32 policy means that the state may be reluctant to co-finance technological or training
33
34 infrastructures in one region in domains where another region is more advanced. Where
35
36 disagreements occur, certain projects are 100% financed either by the state or by the region.
37
38 Ile-de-France failed to find an agreement with the state on the 'research' part of the CPER and
39
40 decided to fund a series of projects on its own. Many regions prefer funding education,
41
42 training and technology transfer than pure research, and are ready to finance a large part of
43
44 specific projects in those fields. For the current CPER, 83% of scientific investments
45
46 (excluding facilities) were realised at the end of 2005. This is due to the high priority attached
47
48 to higher education and research by the state, contrary to other fields like health and social
49
50 action, for instance, where only 64.75% of investments were realised (DIACT, 2006).
51
52
53
54
55
56
57
58
59
60

1
2
3 The CPER has been valued in providing an institutionalised space of negotiation
4
5 between public actors at multiple levels leading to coherence, efficiency and transparency as
6
7 well as synergy around common objectives. Importantly, a review for the French Senate of
8
9 the 3rd generation of CPER (ANDRÉ 2000) highlighted how the CPER has been acknowledged
10
11 as important by regional authorities themselves in the expressions and negotiation of their
12
13 priorities. Yet the report was also damning of the complexity and bureaucracy of the
14
15 procedure and the difficulties experienced by regional authorities in an unequal negotiating
16
17 relationship. It concluded that the state uses an unequal situation to impose its own priorities,
18
19 without coordinating between ministries or giving the collectivities adequate resources for
20
21 successful implementation (ANDRÉ 2000: 342).
22
23
24
25
26

27 Such criticisms were not felt to have been rectified in the 4th planning period (2000-
28
29 2006). The value of CPER to the central state has been judged largely in relation to financial
30
31 co-funding, in the context of dwindling budgets and fewer tools for intervention. This is
32
33 particularly relevant in light of the Lisbon objectives and need to increase spending on R&D.
34
35 Indeed, the share of the state in contributing to the CPER has steadily dropped over the
36
37 contract periods, leading to political tensions with most regional councils (INSTITUT
38
39 SUPÉRIEUR DES MÉTIERS 2006). The relative importance of the CPER as an arena for
40
41 negotiation remains contested. For instance, public managers within the decentralised
42
43 administration consider that the national level defines the whole framework for negotiations
44
45 with little regional variation, while in regional administrations, CPER is viewed as a real
46
47 arena of negotiation.
48
49
50
51
52

53 In light of these criticisms, a new reform of the CPER has changed the ground rules
54
55 for the 5th generation of plans 2007-2013 (CIACT 2006). A further driver has also been the
56
57 European dimension and the need to balance the aims of cohesion and competitiveness. The
58
59 name has changed to *Contrat de Projets Etat-Régions* and will focus on 3 main priorities to
60

1
2
3 avoid a dispersion of projects and fragmentation of effort: competition and the attractiveness
4 of place; the promotion of sustainable development; and social and territorial cohesion. There
5
6 will be a focus on national scale investments and a reinforced and flexible partnership with
7
8 the collectivities. In this respect, regional authorities are now the 'preferred partners' of the
9
10 state, with an enhanced role for other authorities. Importantly, the CPER is seen as a vital
11
12 corollary to the "competitiveness clusters" and necessary for reinforcing research effort and
13
14 the structure of higher education. Although partners are not equal, the CPER provides an
15
16 important arena for the contestation and negotiation of top-down and bottom-up priorities in
17
18 science, research and higher education. Central state actors remain dominant but are
19
20 increasingly passing responsibility for particular elements down to sub-national authorities, in
21
22 the context of the move to networks and clusters. The mechanisms of the CPER could be used
23
24 to further institutionalise this involvement.
25
26
27
28
29
30

31
32 To this extent, the evidence examined so far would seem to support the argument that
33
34 science policy is characterised by multi-level governance dynamics in France. New modes of
35
36 intervention and changes within the specific policy domain of science and research, as well as
37
38 reform of institutional mechanisms through the right to experimentation and CPER, have led
39
40 to intersecting, often task-specific and flexible governance arrangements, indicative of type II
41
42 multi-level governance (HOOGHE and MARKS 2003). A supportive framework for the
43
44 involvement of sub-national authorities in science, research and higher education exists, with
45
46 appropriate, if unequal, arenas for the negotiation and contestation of priorities. However,
47
48 there remain considerable differences in the extent to which regional authorities themselves
49
50 can capitalise upon this context and seize new opportunities to truly develop science-based
51
52 economic strategies. It is to this final 'test' that we now turn.
53

Whilst the potential exists for regional authorities to adopt greater roles in relation to French science and higher education policy, not all regions are currently in a position to fulfil these functions. Looking first at the data, we see certain differences in regional capacities in relation to science-based economic development. Table 2 outlines indicators of R&D in French regions. In absolute value, the most important regions are Ile-de-France and Rhône-Alpes, together accounting for 55% of French R&D. In a second group, we find Midi-Pyrénées and Provence-Alpes-Côte d'Azur (PACA), followed by Aquitaine and Bretagne. In terms of density (R&D / GDP), Ile-de-France is surpassed by Midi-Pyrénées, followed by Rhône-Alpes and Auvergne. Differences also emerge in the nature of regional systems. Auvergne appears typical of industry-led research regions, with Franche-Comté, Haute-Normandie and Picardie; conversely, Languedoc-Roussillon, Nord-Pas de Calais, Lorraine and Alsace are characterized by the strong contribution of public research. Being a strong R&D performer does not imply being specialized in high-tech industries or vice versa: here we see that the small region of Limousin appears very high and Auvergne very low.

A further indicator of regional involvement in science and technology is the proportion of regional budgets devoted to S&T (Table 3). Here again in absolute value the largest regional budgets devoted to Science and Technology (S&T) are those of Ile-de-France and Rhône-Alpes. In terms of expenses per head, Aquitaine is very high and Rhône-Alpes significant, but smaller regions like Languedoc-Roussillon, Limousin and Champagne-Ardenne are among the top five. When looking at the share of S&T in total regional budgets, Aquitaine is still leading and Languedoc-Roussillon noticeable, followed by Rhône-Alpes and Bretagne. Finally, it is possible to compare the shares of technology transfer and scientific projects (research projects, funding for researchers and scientific information) as indicators of technology-oriented vs. science-oriented policy (SANZ-MENENDEZ & CRUZ-CASTRO 2005). Here the data indicates that regions like Ile-de-France, Languedoc-Roussillon, Auvergne,

1
2
3 Alsace and Franche-Comté are mainly interested in technological applications, whereas
4
5 Bretagne, Rhône-Alpes (and Nord-Pas de Calais, albeit with a weaker global effort on S&T)
6
7 manifest a significant relative interest in science. Regional perceptions of science as a
8
9 strategic target clearly vary strongly.
10
11

12 INSERT TABLE 2 AND TABLE 3
13
14

15 In terms of results, a clear relation between input and output can be discerned from the
16
17 data (Table 4), using standard criteria for measuring scientific performance. Among regions
18
19 with high scientific and technological potential, Ile-de-France and Rhône-Alpes look
20
21 relatively strong in technological results (patents), whilst Alsace, Languedoc-Roussillon and
22
23 Midi-Pyrénées also perform well in terms of scientific publications. Ile-de-France, the capital
24
25 region, leads in terms of the density of PhD students, clearly ahead of the next regions:
26
27 Alsace, Midi-Pyrénées and Rhône-Alpes. The number of PhD co-operations between local
28
29 labs and local firms (see CIFRE index in Table 4) can be used as a potential proxy for
30
31 indicating systemic coherence of a regional innovation system – here we see again the pre-
32
33 eminence of Ile-de-France, but with Midi-Pyrénées and Rhône-Alpes in a strong position.
34
35
36
37

38 INSERT TABLE 4
39
40

41 Overall it appears that science-based activities are largely concentrated in only four
42
43 key areas. Ile-de-France remains the only region to host a full range of elements which can be
44
45 seen as constituting an innovation system, though this is synonymous with the national system
46
47 of innovation. Rhône-Alpes can be considered as the sole regional innovation system in
48
49 France with key strengths in electronics, nuclear industries, life sciences, medicine and
50
51 materials. Other regions, like PACA and Midi-Pyrénées, exhibit high-tech districts, but they
52
53 must be considered more as elements of the national innovation system than real endogenous
54
55 and self-organized systems. PACA provides an interesting example of a region in transition,
56
57 however, with Sophia-Antipolis, the first science park in Europe, and the emerging
58
59
60

1
2
3 developments around Caderache and the ITER facility. Similarly, Midi-Pyrénées provides
4
5 specific insights to a regional competence in applied science, based heavily around one sector,
6
7 that of aerospace and clustered in one particular urban area, Toulouse. Across the south of
8
9 France, a sun-belt of regional innovation systems and science-based regional and local
10
11 activity is beginning to emerge.
12
13

14
15 Finance matters and it is clear that the national distribution of resource is significant in
16
17 this respect. The strong performance of Ile-de-France in terms of R&D is not due to a high
18
19 proportion of regional funds invested in S&T (2.1% of regional budget, compared with 2.3%
20
21 average). Yet the quantitative data only reveal a partial explanation of regional difference, nor
22
23 does it necessarily relate to those regions that possess genuine regional science policies. The
24
25 existence of what might be termed 'regional science policy' is determined by the ability of
26
27 regional authorities to define priorities and express a regional view of science; to master
28
29 processes of implementation of regional science strategies and to demonstrate leadership in
30
31 the governance of science and research. In this respect, a general increased interest in S&T as
32
33 a driver of sub-national economic growth masks considerable differences in the capacities of
34
35 different regions to develop science-based development strategies. Within the relatively top-
36
37 down organisation of the French system, implementation processes provide an opportunity for
38
39 variety and self-organisation to emerge.
40
41
42
43
44

45
46 Firstly, the relative magnitude of intergovernmental negotiation mechanisms, such as
47
48 the CPER, is variable. The average level of regional councils' participation in CPER is 35%
49
50 (IGAENR, 2005) yet this rises to 50% or even 80% for certain regions, such as PACA. For
51
52 other regions, such as Ile-de-France and Rhône-Alpes the amounts are lower than 30%,
53
54 leaving greater room for the definition of regional priorities independent of national state
55
56 preferences. Within CPER, regional councils may also encounter difficulties in defining a
57
58 clear 'regional interest' given the nature of sub-national governance arrangements and the
59
60

1
2
3 strength of other collectivités such as departments and cities. This is particularly the case in
4
5 strong university towns, such as Strasbourg. Here the tension between regional and local
6
7 levels becomes particularly apparent: the political acceptability of a regional science policy
8
9 which leads to concentration of resources in particular locations is low and seen to be contrary
10
11 to the need for balanced growth. As a result, science and HE policy develops as a local issue,
12
13 rather than a regional one. Competition can therefore arise between local and regional levels
14
15 where sub-regional levels want to define their own priorities, rather than participate in a wider
16
17 regional strategy, which in turn constrains collective action.
18
19
20
21

22 The formal expression of regional science and higher education priorities also differs
23
24 cross-regionally. Four elements are important in understanding the nature of regional action:
25
26 the size of the region; the nature of the regional science infrastructure; the type of firms and
27
28 the structure of the productive fabric; and the specific scientific/technological fields of
29
30 importance in the region. Socio-political elements have to be taken into account as well,
31
32 linked to regional identity and cultural attitudes concerning science, academic freedom or the
33
34 desirability and extent of public-private partnerships. In Alsace, a historical province with a
35
36 strong collective identity, regional authorities are very proactive in relation to devolution, but
37
38 this attitude is not specifically blatant in the field of science. At the same time, whilst science
39
40 is not necessarily a priority for a region, even if they have strong scientific or technological
41
42 endowments, other policies such as education and training, employment and inclusion may
43
44 have secondary implications for scientific and research establishments.
45
46
47
48
49

50 These differences are reflected in the use made of formal regional consultative
51
52 committees on research (CCRRDT) - involving representatives of a large variety of regional
53
54 actors, in particular from research and industry - with some regions, such as Rhône-Alpes or
55
56 Midi-Pyrénées, more proactive than others, where a regular regional meeting is organized to
57
58 debate on science issues at regional level. Since 1982, regional councils are supposed to
59
60

1
2
3 benefit from their expertise, yet not all regions have created CRRDT at the same time, under
4 the same form, and for the same purpose. Midi-Pyrénées or Bretagne developed and
5 maintained a strong CRRDT, whilst Alsace has a symbolic committee with only a very
6 limited role. Ile-de-France created its own scientific forum (called CCRRESTI) as late as
7 2003. Before 2005, in PACA, the main task of the CRRDT was regional foresight, whereas
8 in Bourgogne or Midi-Pyrénées, it takes part in expertise process-making.

59
60

What emerges from this analysis is a picture of regional differentiation - in terms of the position from which different regions can engage with and capitalise upon the changing national science policy context, as well as develop policies from the bottom up. Yet the data can be misleading - it is not simply the case that a strong science base provides for a coherent regional science policy. Indeed, four rationales for regional science policy in France emerge (see Figure 1):

- Regions that have regional science policies because they have a strong science base (Rhône-Alpes is the paradigm);
- Regions with regional science policies because they want to develop their science base (like Bretagne);
- Regions with weak regional science policies and an average or weak science base (like Auvergne);
- Regions with a strong science base yet weak regional science policies (like Alsace).

INSERT FIGURE 1

This last rationale illustrates the situation in most regions. In Alsace, basic research is proportionally strong, with many world-known university and CNRS teams, but the regional

1
2
3 council does not have a real strategy of promoting such academic assets as a tertiary activity
4
5 per se: its perception of basic research is more about the possible impact it could have on the
6
7 local industrial fabric, although there is a mismatch here as regional firms are generally not
8
9 science-based. In contrast, in Lorraine around Nancy, education and research activities are
10
11 fully welcomed as a substitute for declining industrial activities. Paradoxically, for a long
12
13 time, research has not been a priority for the region of Ile-de-France, probably because the
14
15 S&T system around Paris was viewed as a mainly national construction. But local/regional
16
17 politicians have become aware of the necessity for Ile-de-France to remain a strong region in
18
19 international competition for high-level tertiary activities and now have a pro-active attitude.
20
21 The importance of national investment within Ile-de-France has already been noted,
22
23 explaining in part the relatively modest ambitions of the regional council. With the
24
25 introduction of new mechanisms, such as *pôles de compétitivité*, general changes in attitude
26
27 can be seen across all regions. Yet even in this case, increased regional involvement in
28
29 national science policy does not automatically imply the existence of a real policy at the sub-
30
31 national level.
32
33
34
35
36
37

38
39 Regional science strategy is not linked to the presence of scientific activities in a
40
41 simple and linear way. We have indicated here that several factors explain differences
42
43 between regions and their interpretations of and responses to changes in national science
44
45 policy. Further case study research is needed to determine the relative balance of these factors
46
47 and how they interact to produce distinct regional contexts and capacities for action. The
48
49 modest conclusions that we can draw at this stage are three-fold. Firstly the available evidence
50
51 indicates substantial differences in the positions from where regions engage with the
52
53 emerging multi-level system of science policy governance in France. Secondly, whilst
54
55 national policy conceives of a role for the regions, there remains little evidence that the
56
57 phenomenon of regional science policies is well-spread across regions. Thirdly, only four
58
59
60

1
2
3 regions could be said to be developing into ‘science regions’ which raises questions over the
4
5 long-term viability of the French policy of equity, if not equality.
6
7

8 **A SYSTEM IN EVOLUTION?**

9

10 To what extent can multi-level governance be said to characterise science policy in
11 France? The evidence is partial, indicating that the potential for multi-level governance has
12 not been realised in practice. Shifts in science policy governance reflect ongoing processes
13 rather than being fixed in time.
14
15
16
17
18

19
20 During the last decade, the traditional philosophy of centralised policy design and
21 implementation has changed more in reality than officially advertised. The financial context
22 has encouraged the French state to share certain functions relating to science, research and
23 higher education with local and regional authorities, leading to a more complex governance
24 organisation. More recently another shift in policy can be observed, with (at least partial)
25 bottom-up and competitive procedures being encouraged at the national level. New
26 instruments like “competitiveness clusters” or PRES are designed at the initiative of
27 decentralised actors (universities, territorial communities, firms) and only subsequently
28 ‘labelled’ by the central administration. The example of science policy thus also offers
29 insights into the restructuring of the French administration, in terms of forms of public
30 interventionism, new modes of steering and management and the involvement of the regions
31 in the necessary reconstruction of a globally competitive state. Government is creating
32 frameworks that have to be shaped by territorial configurations, leading to more selective
33 action and resource concentration.
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51

52
53 Within new national frameworks, regions are emerging as intermediate actors within
54 complex governance structures. It is not likely that regional councils can be “the dominant
55 player” but they can mobilise both sub-regional and supra-regional levels to implement their
56 own strategies. Spaces for the negotiation of science policy between national and regional
57
58
59
60

1
2
3 actors have been created and regional science policies are beginning to emerge in certain
4
5 regions. Some of these spaces are institutionalised like the CPER negotiation; others are
6
7 created ad hoc in relation to particular initiatives. However, the French system is less
8
9 characterized by uniformity of regional organisations than it might at first seem. Only two
10
11 strong (Ile-de-France and Rhône-Alpes) and two emerging contenders (PACA and Midi-
12
13 Pyrénées) emerge in terms of participation within a multi-level science polity. As the case of
14
15 Strasbourg illustrates, it might even be that alternative scales emerge as more relevant for the
16
17 construction of local science priorities, such as cities, city-regions or departments. Despite
18
19 identical institutional structures, patterns of implementation diverge.
20
21
22
23

24
25 The emerging dynamics of a multi-level science system therefore pose challenges to a
26
27 traditional centralised French state, with its commitment to balanced growth and regional
28
29 symmetry. New compromises between concentration and balanced growth have been struck
30
31 through networking inter-regional groupings and offering equality of opportunity through
32
33 national competitions. Yet, the principle of territorial equality can no longer be seen as a strict
34
35 rule in national policy: the success of top-down initiatives (and the corresponding distribution
36
37 of resources) depends inherently on the willingness and the capacities of the territories.
38
39 Within an increasingly regionally-sensitive national framework, it is the capability of actors at
40
41 the regional level that determines the extent of multi-level governance in different arenas.
42
43
44

45
46 From a theoretical perspective, it is this issue that appears most interesting. This
47
48 analysis has highlighted three prerequisites for the development of a multi-level polity: a
49
50 national framework that envisages, or even depends on, regional action for the successful
51
52 implementation of its policies; arenas for negotiation of national and regional 'priorities' and
53
54 the capacities and capabilities of regional actors to develop clear strategies from the bottom-
55
56 up. In this case, we see that the central Government remains the key actor in science policy.
57
58
59
60 The state holds the greatest bargaining power and the mobilisation of sub-national authorities

1
2
3 in this domain can be seen, at one level, as little more than a way to increase steering capacity
4 and reduce budgetary pressures. Nevertheless, as a result, relations between the national and
5 the sub-national level are becoming less hierarchical. Interdependence is prevalent. Despite a
6 top-down framework that is beginning to see the regional scale of action as relevant for
7 achieving national objectives and international aspirations, regional awareness of science and
8 research as drivers of economic growth remains low. The tools for multi-level governance to
9 develop exist in this field as in many others; but, as yet, the political context for its
10 materialisation is not present in every region.

TABLE 1

Table 1	
Selected Recent Developments in French Science, Research and Innovation, 2004-2006	
<i>New Organisations</i>	
Agence National de Recherche – ANR (National Agency for Research)	Established in 2005 to distribute funding to research projects chosen according to peer-review on the basis of scientific excellence, with a particular emphasis on applied research and collaborations with industry. In 2006 the budget was €800m for research projects over 4 years divided between response mode projects across all disciplines, specific programmes, industry-academic collaboration and non-project funding.
Agence de l'Innovation Industrielle – AII (Industrial Innovation Agency)	Established in 2005 with €1.7bn over the first two years to give grants and loans to around 10 industry-led R&D programmes, including biomass exploitation, energy efficiency, a new light rail system, the Franco-German search engine Quaero and a mobile TV project. There is also a focus on small and medium sized enterprises, with the aim of 25% small business participation in the AII programmes.
High Council for Science and Technology	Announced in the 2005 Research Bill, the High Council for Science and Technology is charged with advising the President and Government on research strategy and science and innovation policy. It comprises 20 members chosen for their scientific and technological expertise.
AER (Research Evaluation Agency)	Also announced in 2005, the Research Evaluation Agency has been established to ensure the systematic and objective evaluation of research institutes, programmes, groups and scientists. It brings together 24 members to evaluate research in a coherent, transparent manner according to criteria of quality and with concrete effects on the direction of resource.
<i>New Mechanisms</i>	
Pôles de Compétitivité (Competitiveness Clusters)	The competitiveness clusters were announced in July 2005 to promote the development of world-class high technology clusters across France. A three-year budget of €1.5 b over 3 years has been committed with Ministries encouraged to allocate around 25% of their funds to collaborative projects. A cluster has, in a given area, three ingredients (business, higher education and research units) and three key factors (partnerships, R&D projects and international visibility). For the geographical repartition of 67 clusters (66 definitely approved) see Fig.1.
Reseaux Thématique de Recherche Avancée – RTRA (Thematic Advanced Research Networks)	The RTRA, announced in the 2005 Research Bill, are designed to carry out research projects in order to create clusters of internationally excellent science, chosen on through a national competition on the basis of scientific quality, added value and originality. Priority will go to proposals that are cooperative and multidisciplinary, with quality links to economic sectors. The networks will receive substantial funding for new infrastructures and to attract top scientists. A list of 12 regional RTRA (plus one inter-regional in social sciences) has been announced in October 2006.
Pôles de Recherche et d'Enseignement Supérieur – PRES (Research and Higher Education Poles)	The PRES are a mechanism for the coordination of research and HE activities within a particular geographic area, to increase efficiency, visibility and the attractiveness of French HE. There is no national competition or limit to numbers of PRES and no initial finance attached.
Carnot Institutes	The 2005 Research Bill announced €40m for centres of excellence in collaboration between public labs in partnership with industry. 'Institut Carnot' is a quality mark and institutes will receive supplementary funding.

51
52
53
54 ⁱ The numbers in bold characters are the maximum and the minimum of each column. Ile de France and Rhône-
55 Alpes (stressed in grey) clearly emerge, in absolute and relative terms, as leading territories for S&T research in
56 general. Other regions are important for some specificities only: Midi-Pyrénées in R&D intensity and in the
57 proportion of researchers; Franche-Comté, Haute-Normandie and Picardie in firms R&D; Franche-Comté and
58 Limousin for the share of high tech sectors in firms' R&D.

59 ⁱⁱ The numbers in bold characters are the maximum and the minimum of each column. Bretagne and Rhône-
60 Alpes (stressed in grey) show particularly high figures in terms of budgetary investments in scientific projects, as
well as for the global effort in S&T, relative to their size. Regions like Alsace or Auvergne express choices that
are clearly more oriented towards technology transfer than the average of France, and Ile de France funds

1
2
3
4 proportionally very few scientific projects: it is not possible to rank them among the champions of regional
5 science policy, to the contrary of Bretagne and Rhône-Alpes.

6 ⁱⁱⁱ The numbers in bold characters are the maximum and the minimum of each column. Ile de France, Rhône-
7 Alpes, Alsace and Midi-Pyrénées (stressed in grey) show important scores for most of the indicators. But the last
8 column shows that Alsace has not a very high degree of self-sufficiency in science-industry relationships.
