21 *ABSTRACT* Using original survey data collected at the county (commune) level, we examine the
22 relationship between insecurity and welfare. Correcting for unobserved heterogeneity at the
23 commune level, we find that insecurity is associated with lower incomes and health status in all our
24 analysis, and it is associated with lower school enrollment and higher infant mortality in some
25 regressions. Results are robust to the inclusion of shocks potentially affecting both welfare and
26 insecurity. We further find a significant association between insecurity and the provision of certain
27 public services, notably schooling and health care. A similar relationship is found with the
28 placement of development projects. Taken together, the evidence suggests that insecurity is an
29 important determinant of welfare in the country studied.

I. Introduction

It is increasingly recognized that human welfare is affected by the insecurity brought up by war, civil strife, and crime (e.g. Clinard and Abbott, 1973; Bourguignon, 2000). Direct effects arise from victimization and the fear it instills in neighbors, relatives, and members of the community at large. Indirect effects come from reduced investment and incomes and from diminished provision of -- and access to -- public services.

This paper examines the indirect effect of crime-driven insecurity on incomes and public services. We test whether insecurity is associated with a reduction in various welfare indicators. Attempts to investigate this relationship are typically hindered by the need to control for unobserved heterogeneity. We overcome this difficulty by using what amounts to location-specific fixed effects. Other empirical investigations of insecurity and welfare have relied primarily on cross-country comparisons (e.g. Soares, 2004; Fajnzylber, Lederman and Loayza, 2002a, 2002b; Gaviria and Pages, 2001), with all the difficulties inherent to this kind of research -- e.g., different data sources, time period, cultures, etc. Here we use data coming from a single country that were collected at the same time using the same questionnaire. The data covers the whole country.

Results show that an increase in insecurity is associated with a significant reduction in incomes and in access to health centers and schools. The effect is robust to the inclusion of various controls, and the use of alternative methods such as propensity score matching or instrumental variable regression. We also investigate possible channels through which insecurity may affect welfare. We find that a rise in insecurity in a given location is associated with a reduction in the likelihood that a new school or health center is built there. We also provide evidence that insecurity is associated with a reduction in the likelihood of attracting a development project. Results further indicate that certain types of economic activity such as large-scale manufacturing are more sensitive to changes in insecurity than others, like small-scale mining.

These findings are by themselves not surprising. What is surprising is that they are so strong in a country that is not known for drug trade or guerilla activity. In spite of attracting many tourists and sizeable foreign investment, the studied country suffers from what could be called pervasive low-

1
2
3 level insecurity. Much of it is related to property crime and the ineffectiveness of the police and
4 prison system (e.g. Ministère de la Justice, 1999; Fafchamps and Moser, 2003). This study shows
5 that crime and the feelings of insecurity it generates seem to have large welfare effects through
6 economic activity and the provision of public services.
7
8
9

10
11
12 Since Becker's (1968) initial foray, an economic literature on crime has emerged and is now well
13 established in developed countries. Much of this work has focused on the issues of deterrence (e.g.
14 Ehrlich and Brower, 1987; Ehrlich, 1996; Levitt, 1996, 1997, 1998; Farmer and Terrell, 2001) and
15 the determinants of criminal behavior (e.g. Ehrlich, 1975; Blau and Blau, 1982; Sah, 1991; Ludwig,
16 Duncan and Hirschfield, 2001; Morgan, 2000; Freeman, 1996; Raphael and Winter-Ember, 2001;
17 DiIulio, 1996). Some work has also been done on the cost of crime prevention to individuals and on
18 the effect that crime has on investment and the choice of residence (e.g. Cullen and Levitt, 1999;
19 Freeman, Grogger and Sonstelie, 1996; Helsley and Strange, 1999).
20
21
22
23
24
25
26
27

28 More recently, the literature has turned to the study of crime in poor and middle-income countries.
29 In a series of articles relying on cross-country comparisons, Fajnzylber, Lederman and Loayza
30 show that crime-related insecurity hurts growth (e.g. Fajnzylber, Lederman and Loayza, 1998,
31 2000, 2002a, 2002b; Lederman, Loayza and Menendez, 2000). There is also a growing body of
32 work based on micro data. Pradhan and Ravallion (1999), for instance, show that insecurity ranks
33 high on the welfare priorities of Tanzanian dwellers. Demombynes and Ozler (2002) examine
34 crime in South Africa and show that high crime rates in poor districts spill over to richer
35 neighborhoods. Using data from Madagascar, Fafchamps and Moser (2003) show that the incidence
36 of certain categories of crime is higher in isolated areas than in urban centers, thereby reversing the
37 general perception that crime is primarily an urban phenomenon. The authors also show that police
38 deterrence is ineffective in Madagascar. Fafchamps and Minten (2006) further show that an
39 exogenous increase in poverty is associated with a rise in crop theft.

50

51 This literature has recently been joined by economic work on conflicts. Collier and Hoeffler (1998)
52 and Collier and Hoeffler (2002) have shown that many violent political conflicts follow an
53 economic rationale, particularly the capture of a valuable income source such as a diamond mine.
54 Using cross-country evidence, Collier, Hoeffler and Soderbom (2004) show that once initiated,
55
56
57
58
59
60

1
2
3 violent political conflict tends to persist. The relationship between crime and conflicts is examined
4 by Collier and Hoeffler (2004) who provide evidence that conflicts fuel crime but not the reverse.
5 Using panel household data from Uganda which has been plagued by civil war for a decade or
6 more, Deininger (2003) shows that civil strife reduces welfare, but crime does not. In contrast to
7 the existing literature, this paper empirically tests the association between welfare and insecurity
8 and investigates the channels through which these effects are likely to take place.
9
10
11
12
13

14
15
16 The paper is organized as follows. In Section 2, we briefly present the conceptual framework and
17 testing strategy. Section 3 discusses the data and presents summary statistics. In Section 4 we test
18 whether insecurity reduces welfare. Section 5 examines a number of channels through which
19 insecurity affects welfare. Conclusions and suggestions for further research are presented at the
20 end.
21
22
23
24

25 26 **II. Conceptual Framework**

27
28
29 Following Becker (1968), it is now customary to recognize that crime responds to economic
30 incentives. Crime is also widely believed to affect economic incentives, although the magnitude of
31 this effect is unclear. Other sources of insecurity, such as riots, civil wars and political conflict, are
32 similarly thought to influence economic outcomes.
33
34
35
36
37
38

39 To investigate the relationship between insecurity and welfare, we estimate regressions of the form:

$$40 \quad W_{it} = \alpha S_{it} + \beta C_{it} + \mu_i + \varepsilon_{it} \quad (1)$$

41
42 where W_{it} is a welfare indicator for location i at time t , S_{it} is a measure of insecurity, C_{it} is a vector
43 of controls, μ_i is a fixed effect, and ε_{it} is an error term. The fixed effect captures any location-
44 specific time-invariant factor that may affect welfare. Controlling for such effects is essential
45 because many location-specific features such as isolation or population density may influence
46 welfare as well as insecurity. Failing to control for these factors may generate a spurious correlation
47 between welfare and insecurity.
48
49
50
51
52
53
54

55 Differencing (1) to eliminate the fixed effect, we obtain a regression model of the form:

$$56 \quad \Delta W_{it} = \alpha \Delta S_{it} + \beta \Delta C_{it} + \Delta \varepsilon_{it} \quad (2)$$

1
2
3
4
5 where the notation $\Delta x_{it} \equiv x_{it} - x_{it-1}$. Equation (2) regresses changes in welfare on changes in
6 insecurity, controlling for various other effects so as to minimize omitted variable bias. Estimating
7 (2) for various welfare indicators is the first purpose of our econometric analysis.
8
9

10
11 We also wish to investigate the channels through which insecurity may affect welfare. To do so, we
12 examine whether insecurity is associated with a number of potential channels N_{it} which are
13 generally regarded as strongly related with specific dimensions of welfare. For instance, health is
14 affected by the presence or absence of health facilities. We can therefore test whether an increase in
15 insecurity is associated with a lower likelihood of creation of a health facility in a given location,
16 i.e., whether:
17
18
19
20
21

$$\Delta N_{it} = \gamma \Delta S_{it} + v_{it} \quad (3)$$

22
23
24
25
26 Here as before, differentiating eliminates time-invariant fixed effects that may be correlated with
27 insecurity as well as with the presence of a health facility.
28
29
30

31 III. The Data

32
33
34
35 The purpose of the rest of this paper is to estimate equations (2) and (3) using comprehensive
36 survey data on Madagascar. Madagascar constitutes a perfect test case for an investigation of
37 insecurity and welfare. The country is quite poor, with a GDP per head of US\$260 in 2002 (World
38 Bank, 2003). The Malagasy government estimates that 69% of the population are below the poverty
39 line (e.g. GOM, 2003; Mistiaen, Ozler, Razafimanantena and Razafindravonona, 2002). The
40 country is also known to have a high crime rate (Fafchamps and Moser, 2003).
41
42
43
44
45
46

47
48 A map of Madagascar with provincial and communal boundaries is shown in Figure 1. Population
49 density is depicted in shades of grey. With a population of 16 million and a size equivalent to that
50 of France, Belgium, and Holland combined, Madagascar has a low population density -- the median
51 population density in each commune is 26 inhabitants per square Km. We see that population is
52 densest in the Central highlands around the main cities of Antananarivo (the capital city) and
53 Antsirabe. The Eastern highlands and coast between Toamasina and Fianarantsoa are also heavily
54
55
56
57
58
59
60

1
2
3 populated. This largely reflects climate patterns that make these areas more productive for
4 agriculture. Other major cities such as Toamasina, Mahajanga, Toliara, and Antsiranana are coastal
5 port cities with a small rural hinterland surrounding them. The Western and Southwestern parts of
6 the country are more arid and much less populated.
7
8
9

10
11
12 Although Madagascar has not experienced any major armed conflict since independence,^{iv}
13 insecurity is known to be a major problem. Fafchamps and Moser (2003) provide evidence that the
14 homicide rates are comparable to that of the US in the early 1990s, when they were at its highest.
15 Cattle rustling is a major problem in low population density area, with extremely high rates of
16 cattle theft and the involvement of organized crime (e.g. Rasamoelina, 2000; Razafitsiamidy,
17 1997). Crop theft is also a commonly cited problem, and Fafchamps and Minten (2006) show an
18 exogenous increase in poverty to be associated with a rise in crop theft.
19
20
21
22
23
24
25

26
27 Insecurity appears to be related to insufficient law enforcement. Ministère de la Justice (1999) and
28 Root (1993) provide ample evidence that the legal system is not running effectively. Fafchamps
29 and Moser (2003) show that law enforcement has no deterrent effect on crime. Survey responses
30 suggest that, in some parts of the country, criminals who are caught do not spend any time in jail
31 because of inefficient courts and lax prison rules. In these circumstances, we would expect
32 insecurity to have a measurable impact on welfare.
33
34
35
36
37
38

39
40 The data on which we base our empirical analysis comes from a survey conducted by the authors in
41 2001. Our unit of analysis is the commune, a geographically defined administrative unit roughly
42 equivalent to a municipality or county. Madagascar has six provinces (or faritany), which are
43 divided into fivondronanas. The fivondronana are made up of communes -- the smallest
44 administrative units with direct representation from the central or provincial government. Rural
45 communes are further divided into fokontanys, which essentially represent individual villages. As
46 of late 2001, there were approximately 1390 communes in Madagascar.^v
47
48
49
50
51
52

53
54 The crime statistics and other data used in this paper were all collected as part of the commune
55 survey. The survey was conducted over a three-month period in 2001 in collaboration between
56 Cornell University, Oxford University, and the Malagasy agricultural research institute (FOFIFA).
57
58
59
60

1
2
3 A total of 1385 communes were surveyed, all but 9 currently functioning communes.^{vi} The
4 remoteness of some communes and the general lack of national data on certain subjects meant that
5 little was known about the spatial distribution of public goods and services, economic activity, or
6 insecurity prior to the survey.
7
8
9

10
11
12 The survey was conducted at the commune's administrative center. Enumerators were instructed to
13 gather a number of statistics from the relevant government offices in the commune. More
14 subjective questions, such as those concerning community perceptions of existing conditions, were
15 answered by a focus group composed of a small group of prominent residents of the commune --
16 typically municipality officials and key informants. Crime statistics were collected only for 1999,
17 2000 and 2001 so as to minimize recall bias. To the best of our knowledge, there does not exist
18 systematic time series crime data on all the municipalities of the country.
19
20
21
22
23
24
25

26
27 Descriptive statistics on insecurity and welfare are presented in Table 1. Focus group respondents
28 were asked whether insecurity improved or worsened in their commune over the five years period
29 preceding the survey. Their subjective assessment is reported in the first column of Table 1. We see
30 that 30% of respondents estimate that the level of insecurity in their commune improved between
31 1996 and 2001 while 51% estimate that it worsened. Only 19% responded that it remained
32 unchanged.
33
34
35
36
37
38

39 Focus group respondents were also asked whether average income in the commune increased or fell
40 over the same period. Responses are summarized in column 2 of Table 1. In half of the communes,
41 respondents stated that the average income in their commune rose while 35% stated that it fell.
42 Similar questions were asked regarding the health status of inhabitants, school enrollment, and
43 infant mortality in the commune. The reader should keep in mind that, for the first three variables
44 an increase is good, but for infant mortality it is bad. A majority of respondents felt that health
45 status and school enrollment have increased, while infant mortality has decreased.
46
47
48
49
50
51
52

53 Many of the nefarious effects of insecurity depend on perceived risk and thus on perceptions of
54 insecurity. Responses to the insecurity question therefore provide a measure of insecurity that is
55 more economically relevant than actual crime statistics. The reader may nevertheless wonder
56
57
58
59
60

1
2
3 whether subjective perceptions by focus group respondents bear any relationship with actual risk.
4 To investigate this, we compare subjective perception of insecurity to crime incidence figures.
5
6
7

8
9 Respondents were asked to rank the security situation in their commune. Responses, presented in
10 Table 2, show that 28% of respondents find the security situation either bad or very bad while 25%
11 find it good or very good. The others find it average. Recognized high crime areas have been
12 flagged as a 'red zone' by the government; 30% of the country's communes are counted as part of
13 the 'red zone'. Table 2 also presents stated development priorities of commune respondents.
14 Insecurity comes third in this ranking, being the top development priority for 15% of the
15 communes, and second priority for another 13% of communes. Insecurity is especially a concern in
16 remote communes, a result in line with the work of Fafchamps and Moser (2003). Since remote
17 communes also tend to be larger, when we weigh responses by area we find that insecurity is the
18 first or second development priority in communes representing 43% of the country's area.
19
20
21
22
23
24
25
26
27

28 It is of interest to examine whether subjective assessments of insecurity are related to actual
29 insecurity. Given the absence of civil unrest during the period under investigation, crime must be the
30 primary source of insecurity. In the second panel of Table 2 we report crime statistics collected in
31 the commune survey. These statistics were collected separately for 1999, 2000 and 2001. Here they
32 are averaged over the three year period 1999-2001 and reported per 100,000 inhabitants.
33
34
35
36
37
38

39 Of the five types of criminal activity recorded in the commune survey, cattle rustling is the most
40 common. An average of 80 or so head of cattle are stolen on average each year in each commune --
41 an average of 1500 or so head of cattle per 100,000 inhabitants. This figure is influenced by a
42 number of a small number of very large outliers where cattle rustling takes place at an 'industrial'
43 level. But the median is still 62 head of cattle reported stolen each year per 100,000 inhabitants.^{vii}
44 Burglaries are the next most common type of crime, with some 43 burglaries on average per year
45 per 100,000 inhabitants. The average number of reported homicides is higher than the high US
46 national average from the early 1990's: 8.5 homicides per 100,000 inhabitants (Fox and Zawitz,
47 2000). This number is a bit higher than the 1994 national average of 6.4 intentional homicides
48 reported in Fajnzylber et al. (1998). The median number of homicides is much lower, suggesting
49 that crime is concentrated in certain communes. As shown by Fafchamps and Moser (2003), the
50
51
52
53
54
55
56
57
58
59
60

1
2
3 highest homicide rates are found in isolated, less densely populated areas. The incidence of rape
4 appears low, with less than three reported cases on average per 100,000 inhabitants. This is likely
5 due to under-reporting bias. Vehicle theft is extremely rare, reflecting the low number of personal
6 vehicles on the island and the fact that few people know how to drive.
7
8
9

10
11
12 To ascertain the validity of the subjective assessment of the security situation by survey
13 respondents, we would like to regress this ranking on crime statistics. Before we do so, however,
14 we worry that the responses given in the commune survey may be influenced in a systematic
15 manner by the composition of the focus group. It is conceivable, for instance, that members of
16 specific professions may be more sensitive to crime and tend to over-report it. To the extent that the
17 composition of the focus group is correlated with location and crime, this may result in a spurious
18 relationship. At the bottom of Table 2 we present the information we have regarding the
19 composition of focus groups. The average number of participants is close to 9 people. Communal
20 employees and social service workers represent over 60% of the respondents. This is unsurprising
21 since they are likely to be the best source of quantitative information about communal affairs.
22 There is also a non-negligible proportion of farmers and this proportion varies from focus group to
23 focus group.
24
25
26
27
28
29
30
31
32
33
34

35 Table 3 reports an ordered probit regression of the subjective insecurity ranking on the five crime
36 rate variables and the red zone dummy. Focus group variables are included to control, to the extent
37 possible, for response bias. Results demonstrate that insecurity as perceived by focus group
38 respondents largely reflects actual crime: the red zone dummy and three of the five crime variables
39 are significant -- often at the 1% level.^{viii} Car theft is not significant, most probably because it is
40 very rare. From these observations we conclude that the subjective assessment of insecurity
41 reported by respondents is closely related with objective risk measures; it is not just driven by
42 irrational fear and prejudice.
43
44
45
46
47
48
49
50

51 These results are consistent with earlier studies which have shown that, in Madagascar, perceived
52 insecurity is significantly related to the prevalence of crime which, in the studied country, increases
53 with isolation (Fafchamps and Moser, 2003) and poverty (Fafchamps and Minten, 2006). While in
54 developed economies most crime occurs in urban areas, Fafchamps and Moser (2003) have shown
55
56
57
58
59
60

1
2
3 that in Madagascar crime rates are higher in isolated rural areas and that much crime is associated
4 with cattle rustling. This is confirmed in Table 3: cattle theft has a strong effect on feelings of
5 insecurity, either directly (the coefficient of cattle theft has a *t*-value close to 8) or indirectly
6 through the 'zone rouge' (high crime) dummy, which is exclusively rural and concentrated in high
7 cattle theft areas. Anthropological studies of cattle theft in Madagascar document the role of
8 organized roaming gangs that steal cattle from one commune and walk it over long distances to sell
9 it elsewhere. Similar observations have been made for Northern Kenya by McPeak and Barrett
10 (2001).
11
12
13
14
15
16
17
18

19 **IV. Insecurity and Welfare**

20
21
22 We now examine the relationship between perceived insecurity and the four welfare measures
23 collected in the survey -- income, access to health care, access to schooling, and infant mortality.
24 Since all five measures compare the situation prevailing at the time of the survey with that
25 prevailing five years earlier, they are already in differenced form, i.e., as they appear in equation
26 (2).
27
28
29
30
31
32

33 Ordered probit regression results are presented in Table 4. Focus group composition variables are
34 included as controls for possible response bias. Results show a strong negative association between
35 an increase in insecurity over the period 1996-2001 and an improvement in income, health status,
36 and school enrollment. Put differently, communes that experienced an increase in insecurity
37 experienced a significantly lower increase in income, health status, or school enrollment. Infant
38 mortality increases with insecurity but the effect is not statistically significant. These results
39 suggest that insecurity is significantly and negatively associated with several dimensions of
40 welfare.
41
42
43
44
45
46
47
48

49 The question that immediately follows is through what channel(s) this relationship occurs. Before
50 we turn to this question, however, we must verify that the results shown in Table 4 are robust. The
51 first possibility we investigate is the idea that both insecurity and welfare were affected by some
52 other factor, resulting in a spurious relationship. For instance, it is conceivable that communes
53 affected by a cyclone or a drought experienced a fall in income and a rise in insecurity, as shown
54
55
56
57
58
59
60

1
2
3 for instance for Tanzania by Miguel (2003). To reduce the chance of such omitted variable bias, we
4 include as additional regressors a number of variables capturing a wide variety of shocks. This
5 approach does not entirely eliminate the risk of omitted variable bias, but it is the best we can do
6 with the data at hand.
7
8
9

10
11 Shock variables are described in Table 5. Each variable measures the number of years, over the
12 three years preceding the survey, during which a given shock or disease affected the commune.
13 Each variable takes values from 0 (no year) to 3 (in all three years). As evidenced by Table 5, the
14 list of shock variables is quite long as it includes climatic events (cyclone, drought, flood), plant
15 pests and diseases (locusts, rice fleas), human diseases, and livestock diseases. Bad climatic events
16 are a frequent occurrence, the late start of the rains being the most often cited shock. Cyclones hit
17 the East coast of the country every year, devastating crops, causing floods, and cutting roads. Some
18 human diseases, malaria for instance, are endemic in most of the country so there is very little
19 variation from year to year. Others such as plague vary over time.
20
21
22
23
24
25
26
27
28
29

30 An additional source of concern is the possibility that disgruntled or pessimistic focus groups may
31 respond to all questions in a negative manner. This would generate a response bias that would be
32 common to the insecurity variable and the variables measuring changes in welfare over time. The
33 analysis presented in Table 2 suggests that subjective perceptions about the *level* of insecurity
34 correlate well with objective measures of crime, but here we are concerned about subjective
35 perceptions about *changes* in insecurity. Unfortunately commune-level crime statistics going back
36 to 1996 and before do not exist for Madagascar. Consequently we cannot conduct the same analysis
37 as we did in Table 2 by regressing perceptions about changes in insecurity on changes in reported
38 crime between 1996 and 2001.
39
40
41
42
43
44
45
46
47

48 We seek to address this concern by constructing two proxies for 'gripe'. Including these proxies as
49 additional controls should reduce the omitted variable bias. We also construct our first proxy for
50 gripe using the residual from the regression presented in Table 3. For memory, in that regression
51 we regress the *level* of insecurity -- as reported by the focus group at the time of the survey -- on
52 recent crime statistics. The error term from this regression can be taken as a proxy for the focus
53 group's tendency to over-report insecurity.
54
55
56
57
58
59
60

1
2
3
4
5 The second proxy we construct uses answers to focus group questions that are not directly related
6 to welfare or insecurity but are likely to be correlated with 'gripe'. More specifically, we use
7 answers to questions on late rains and total rainfall over the three years preceding the survey, as
8 reported by the focus group. We combine answers to construct an index of how much the
9 respondents complained about bad rains. We then regress this index on the value of the same index
10 averaged over neighboring communes. The idea is that rainfall in communes nearby should be
11 correlated with own rainfall but not with the pessimistic temperament of the respondents. Results
12 are shown in Appendix, Table A1. The regression is highly significant, with an R^2 of 0.24. The
13 residual from this regression measures how much more than neighboring communes the
14 respondents complained about rainfall. This residual is a proxy for gripe if we are willing to assume
15 that rainfall is spatially correlated -- so that rainfall in neighboring communes is a good predictor --
16 and that gripe is distributed more or less independently across communes. While there is little
17 doubt about the first assumption, we unfortunately have no way of verifying the second. The
18 validity of the procedure therefore rests on this maintained assumption.
19
20
21
22
23
24
25
26
27
28
29
30

31
32 Table 6 presents ordered probit regressions of changes in welfare indicators on changes in
33 insecurity, the composition of the focus group, the two proxies for 'gripe', and the various shock
34 and disease variables listed in Table 5.^{ix} We see that the insecurity coefficients retain the same sign
35 and magnitude in all four regressions. They remain significantly negative in the first two
36 regressions, but they are not significant in the other two. Except for one coefficient which is
37 significant at the 10% level, the gripe variables are not significant.
38
39
40
41
42
43

44 Although shock and disease variables are used here only as controls, it is instructive to check
45 whether they have the anticipated effect. We find that many climatic shocks are associated with a
46 fall in welfare. For instance, floods, droughts, and late rains all tend to reduce income. Typhoid is
47 associated with a fall in health status and school enrollment. Other results are more puzzling, such
48 as the positive association between other livestock diseases and improvement in two of our welfare
49 indicators. In this case, it is possible that higher prosperity leads households to buy, sell, and keep
50 more livestock, thereby creating conditions favorable to epidemics. The positive association
51
52
53
54
55
56
57
58
59
60

1
2
3 between plant diseases and income and health status may be due to the fact that plant diseases are
4 more common in humid years when incomes are high.
5
6
7

8
9 It is conceivable that recent shocks loom larger in respondents' assessment of improvements in
10 welfare. To investigate this possibility, we reestimate Table 6 using only shocks reported to 2001.
11 Results, not shown here to save space, are basically identical to those reported in Table 6. We also
12 worry that, given the high frequency of many reported shocks, they approximate average incidence
13 rather than shock. To correct for this possibility, we regress shock measures on a large number of
14 commune physical characteristics, such as latitude, longitude, elevation, average rainfall, and the
15 like. The residuals from these regressions represent variation in shock variables that cannot be
16 attributed to time-invariant characteristics. We then obtain the residuals from these regressions and
17 use them as proxies for unanticipated shocks in Table 6. Results, not shown here to save space,
18 yield a stronger estimated effect of the insecurity variable, which is significant not only in the
19 income and health status regressions but also in the infant mortality regression.
20
21
22

28

29
30 As emphasized in the literature on treatment effects (e.g. Lee, 2005; Wooldridge, 2002), the results
31 in Table 6 may be misleading if treated and untreated observations have very different values of the
32 control variables. The linear functional form imposed by the regression framework can yield
33 misleading results if the true slope of the treatment effect varies across communes with different
34 characteristics (Dehejia and Wahba, 1999). To correct for this possibility, we need to compare
35 treated and untreated communes that are comparable. Various non-parametric matching techniques
36 have been proposed that seek to compare treated observations only to untreated observations with
37 similar observable characteristics. One of these methods is propensity score matching, but there are
38 more general matching methods as well.
39
40
41
42
43
44
45
46

47 To fit our analysis into this framework, let us define as treated those communes that suffered an
48 increase in insecurity; those that did not are controls. Roughly half of the communes fall in each
49 category. We report in Table 7 the results obtained using two different matching techniques.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 The first one is the nearest neighbor matching method proposed by Abadie, Drukker, Herr and
4 Imbens (2004). To understand how this method works, say the vector of covariates is x . We want a
5 measure of distance between the x 's. One easy metric is the vector norm $(x'Vx)^{1/2}$ where V is
6 a positive definite weight matrix. The distance $\|x_1 - x_2\|_V$ between two vectors x_1 and x_2 is then

$$\|x_1 - x_2\|_V = ((x_1 - x_2)'V(x_1 - x_2))^{1/2}$$

11 Abadie et al. (2004) recommend letting $V = S^{-1}$ where S is the covariance matrix of covariates x .
12 This metric is referred to as the Mahalanobis metric. We implement this method using all the
13 controls appearing in Table 6 as part of the covariate vector x .
14
15
16
17
18

19 The second set of results reported in Table 7 is based on propensity score matching. In this method,
20 we begin by regressing treatment on the controls, the results of which are shown in Table A2 in
21 appendix.^x The predicted probability of treatment generated by this regression is called the
22 propensity score. Rosenbaum and Rubin (1983) have shown that, as long as there is no selection on
23 unobservables, the effect of the treatment can be consistently measured by comparing treated and
24 untreated communes with similar propensity scores.
25
26
27
28
29

30 Estimates of the average treatment effect for our four welfare variables of interest are presented in
31 Table 7, using common support. For propensity score matching, we use the radius method with a
32 caliper of 0.1 as this yields the most stable results. For comparison purpose we also report results
33 for the unmatched. Results are very similar to those reported in Table 6: both matching estimators
34 yield a significant difference between treated and control for average income and health status, but
35 no significant effect infant mortality and school enrollment. This confirms that the results reported
36 in Table 6 are not an artifact of the regression framework.
37
38
39
40
41
42
43
44

45 There remains the possibility that the gripe variables do not fully control for response bias. The
46 resulting measurement error in the insecurity variable may lead to endogeneity bias. In an attempt
47 to correct for this source of bias, we seek to instrument the insecurity variable. To do this, we need
48 to find an instrument for the change in insecurity over the years preceding the survey. We use the
49 population census of 1993 to construct two variables that are likely to affect subsequent changes in
50 crime but could not have been caused by it. In Madagascar, the presence of young men in the
51 village is likely to improve the security situation. This is because rural insecurity is often due to
52
53
54
55
56
57
58
59
60

1
2
3 gangs that attack villages to steal cattle, a point that has been emphasized repeatedly in the
4 anthropological literature (e.g. Rasamoelina, 2000; Razafitsiamidy, 1997) and in regression
5 analysis of crime in Madagascar (Fafchamps and Moser, 2003). Young males make communities
6 less vulnerable to such attacks and may serve as a deterrent.^{xi}
7
8
9

10
11
12 To capture this idea, we construct a variable that measures the growth in the proportion of teenage
13 males in the commune population. The 1993 population census report age in 5-year categories.
14 Males aged 10 to 14 in 1993 will be between 13 and 17 in 1996 and between 18 and 22 in 2001.
15 These are the teenage males in the recall period covered by the commune survey. Let their
16 proportion in the population be written S_{10-14} . In contrast, males aged 15 to 19 in 1993 were
17 teenagers at the time of the census but have basically become adults by the time of our recall
18 period. Let their proportion in the population be written S_{15-19} . The regressor is $\Delta S = S_{10-14} - S_{15-19}$; if
19 it is positive, there are more teenage males during the survey recall period relative to the preceding
20 5 year period -- and vice versa if it negative. If the presence of teenage males deters thieves, the
21 variable should have a negative effect on insecurity: more teenage males relative to the preceding
22 period reduces insecurity. To allow for spillover effects across communes, we use ΔS in
23 neighboring communes as additional regressor in the propensity score regression. While this
24 identification strategy is not ideal -- i.e., it does not rely on a controlled or quasi experimental
25 source of variation in insecurity -- it should satisfy the exclusion restriction and it is the best we can
26 do with the available data.
27
28
29
30
31
32
33
34
35
36
37
38
39

40
41 The instrumenting regression, shown in Table A3 in appendix, is basically the same as Table A2
42 except that it includes two more variables and is estimated using least squares. As expected, a
43 higher proportion of young males is associated with a smaller increase in insecurity. The population
44 variables are jointly significant but the value of the joint F -test is below 10, suggesting that we have
45 a weak instrument problem.
46
47
48
49

50
51 Regression results with instrumented insecurity are shown in Table 8. Overidentification tests of
52 the validity of the instruments fail to reject the null hypothesis that instruments are uncorrelated
53 with the errors in the main regression. Since we have weak instruments we apply the Anderson-
54 Rubin test as implemented by Moreira (2001). This procedure corrects the threshold value for the
55
56
57
58
59
60

1
2
3 significance of the insecurity variable that allows for weak instruments. The results from this test
4 are reported at the bottom of Table 8.
5
6
7

8
9 Results show a massive increase in the magnitude of the insecurity coefficient (6.5 to 25 times
10 larger). This is consistent with the presence of measurement error, uninstrumented results suffering
11 from attenuation bias. This is hardly surprising given that subjective rankings are known to vary
12 with mood, time of the day, and other psychological and physiological factors (e.g. Frey and
13 Stutzer, 2002; Diener, Suh, Lucas and Smith, 1999; Layard, 2002). After instrumentation, the
14 insecurity variable is significant with the anticipated sign in the income, health status, and infant
15 mortality regressions. These results accord serve as an additional confirmation that the association
16 between changes in welfare and insecurity is not simply a consequence of response bias.
17
18
19
20
21
22
23

24 **V. Possible Channels**

25
26
27
28 Having documented a robust relationship between insecurity and certain dimensions of welfare, we
29 briefly examine possible channels through which this relationship may take place. We begin by
30 reporting the opinion of the respondents. Each focus group was asked to provide the main cause for
31 the change in each of the four welfare indicators. Their responses, broken into categories, are
32 summarized in Table 9.
33
34
35
36
37

38
39 The most often cited cause for variation in income is a change in agricultural prices.^{xiii} Insecurity
40 is listed as the main reason for change in income by 8% of the communes. This is a fairly
41 remarkable result since a change in insecurity must be quite severe before being given as the main
42 reason for changes in income in the commune as a whole. The provision of a new health center and
43 of a new school is given as the most important reasons for changes in health status and school
44 enrollment, respectively. Health facilities also loom large in responses regarding infant mortality.

Contrary to income, insecurity is not often listed for health status, school attendance, and infant mortality. This may be misleading, however, because insecurity may hinder or delay the construction of new schools and health centers in affected communities.

1
2
3 To investigate this issue more in detail, we test whether an increase in insecurity is associated with
4 a lower probability of attracting public services into the commune. We have information on when
5 various infrastructures and services were first established in the studied communes. This
6 information is summarized in Table 10 which shows the proportion of communes with the
7 infrastructure or service in 1996 and 2001. We see that the study period witnessed a fairly large
8 increase in the provision of secondary schools, basic health centers, and drinking water. The
9 increase in agricultural input and output markets was less pronounced.
10
11
12
13
14
15
16

17
18 Based on the information presented in the first panel of Table 10, we create dummy variable that
19 takes the value 1 if a new infrastructure or service was instituted in the commune during the 1996-
20 2001 period. We then regress this dummy on the change in insecurity during the same period, as
21 shown in equation (3). Of course, this regression is conditional on the commune not already having
22 the infrastructure or service in 1996. We therefore estimate the model as a selection-corrected
23 probit. Because the selection equation seeks to explain the level of infrastructure in 1996 -- not the
24 change in the subsequent period -- we use time-invariant commune characteristics as regressors for
25 the selection equation. To minimize selection bias in the change equation, we use a generous list of
26 regressors including various geographical features thought to affect either the demand for public
27 services or the cost and political desirability of providing them. The list includes longitude and
28 latitude (major determinants of climate and thus of agricultural potential), elevation (Madagascar is
29 a mountainous country), rainfall, temperature, soil type dummies, population density (based on the
30 1993 census), distance from the nearest road, and ethnic and provincial dummies. All these
31 regressors are clearly pre-determined and most are beyond human influence. Since these regressors
32 are not our focus of interest, we need not discuss them any further. As before, we include gripe
33 proxies in the welfare regressions and we control for the composition of focus groups.
34
35
36
37
38
39
40
41
42
43
44
45
46

47
48 Regression results shown in Table 11 indicate that an increase in insecurity is associated with a
49 lower likelihood that a secondary school or health center is built. Other public infrastructures such
50 as drinking water and agricultural markets appear unaffected. The tentative conclusion we can draw
51 from this and the earlier evidence is that insecurity affects welfare at least partly through lower
52 provision of certain public services. It is worth noting that the two public services affected by
53 insecurity, secondary schools and health centers, both require that an educated workforce (teachers,
54
55
56
57
58
59
60

1
2
3 doctors and nurses) live in the commune or nearby. Agricultural input and output markets, in
4 contrast, are operated by small local traders who move across markets and need not reside in the
5 affected areas (e.g. Fafchamps and Minten, 1999; Fafchamps, Gabre-Madhin and Minten, 2005).
6
7 This contrast suggests that one factor that hinders the delivery of public services to insecure areas is
8 the difficulty to convince teachers and health workers to work and reside there.
9
10
11

12
13
14 We also have information on the number of new development projects taking place in the
15 commune over the 1996-2001 period. As shown in Table 10, during this period the average number
16 of new development projects per commune was 2.23 with a median of 2. Only 19% of communes
17 did not have a new development project during the period. We regress the (log of the) number of
18 new development projects (+1) on the change in insecurity. Results, presented in Table 12, again
19 show a negative relationship: communes that experienced a deterioration of the security situation
20 received fewer new development projects. The magnitude of the effect is non negligible: if the
21 security situation worsened a bit instead of staying the same, this results in a 6% fall in the number
22 of projects undertaken in the commune. Going from 'worsened a lot' to 'improved a lot' results in a
23 25% increase in the number of development projects. Given that development projects typically
24 aim at increasing incomes and improving welfare, this evidence suggests that insecurity also lowers
25 welfare by discouraging the placement of development projects in affected areas.
26
27
28
29
30
31
32
33
34
35

36
37 We conduct a similar analysis on manufacturing and mining employment. Results -- not shown
38 here to save space -- show a significant negative effect of an increase in insecurity on employment
39 growth in large manufacturing firms (more than 50 employees), but no effect on mining
40 employment and on smaller manufacturers. To the extent that large firms depend more on
41 sophisticated equipment and educated manpower, this again suggests that insecurity is less harmful
42 to traditional, informal income generating activities than it is to economic activity of a more
43 modern nature.
44
45
46
47
48

49
50
51 The survey also provides some evidence that insecurity has a negative effect on agriculture.
52 Respondents were asked what factors hinder the expansion of cultivated acreage in lowland
53 (irrigated) and upland (non-irrigated) areas. Insecurity was cited by 10% of respondents for lowland
54
55
56
57
58
59
60

1
2
3 expansion and by 23% of respondents for upland expansion.^{xiii} Insecurity is cited more often in
4 land-abundant communes that are more remote and where insecurity is higher.
5

6
7 Based on the work of Fafchamps and Minten (2006), Rasamoelina (2000), and Razafitsiamidy
8 (1997), the fear of crop theft and of encounters with cattle thieves may be the dominant concerns of
9 villagers. This provides yet another channel by which insecurity affects welfare: the fear of
10 venturing too far from the village appears to discourage many farmers from expanding cultivated
11 acreage and hence output.
12
13
14

15 16 17 **VI. Conclusion** 18

19
20
21 Using original data collected by the authors, this paper has examined the relationship between
22 insecurity and welfare. Identification of this relationship is not based on a controlled or natural
23 experiment, so causal inference is potentially problematic and results should be interpreted in this
24 light. We do, however, control for commune fixed effects – arguably the main cause for concern in
25 analyses of this type. We also do our best to check the robustness of our results with respect to
26 potential sources of bias, in particular omitted variable bias and response bias.
27
28
29
30
31

32
33 The results show that an increase in insecurity, as perceived by respondents, is associated with
34 lower incomes, school enrollment, and health status, and with a higher infant mortality. This
35 association is consistently significant for incomes and health status. For school enrollment and
36 infant mortality, it is only significant for some estimators. Results are robust to the inclusion of
37 shocks potentially affecting both welfare and insecurity. These findings are in contrast to those of
38 Deininger (2003) who found no effect of crime on rural incomes in Uganda.
39
40
41
42
43
44

45
46 We then turned to the channels through which insecurity may affect welfare. We find a significant
47 relationship between an increase in insecurity and improvements in the provision of certain public
48 services, notably schooling and health care. We find a similar relationship with the placement of
49 development projects. We also find some evidence that insecurity is associated with an
50 employment reduction in large manufacturing firms – but not in mining -- and that it discourages
51 farmers from expanding cultivated acreage.^{xiv}
52
53
54
55
56
57
58
59
60

1
2
3 Taken together, the evidence suggests that insecurity is probably an important determinant of
4 welfare in the country studied. Insecurity seems to affect welfare in many ways: through incomes
5 via its effect on economic activity and development projects; and through access to public services
6 by hindering the placement of social infrastructures in insecure areas. Certain types of public
7 services -- schools and health centers -- and certain types of economic activity -- e.g., large-scale
8 manufacturing -- appear more sensitive to insecurity than others such as mining and agricultural
9 trade.
10
11
12
13
14
15

16
17 These findings raise the issue of why insecurity is so pervasive in Madagascar. The lax attitude of
18 police, courts, and jail institutions appears largely responsible for this state of affairs (e.g. Root,
19 1993; World Bank, 1995). Fafchamps and Moser (2003), for instance, show that police presence
20 has no deterrent effect on crime in Madagascar. Based on a survey of legal institutions in the
21 country, the Ministère de la Justice (1999) documents many shortcomings in the implementation of
22 existing laws. In particular, it is common for convicted criminals to be allowed out of jail in
23 exchange for money. As a result, only petty criminals who cannot afford to pay remain in prison.
24
25
26
27
28
29
30

31 To further investigate this possibility, a question on jail effectiveness was asked to focus group
32 respondents in a follow-up survey.^{xv} Respondents were asked whether, if a major cattle thief were
33 found in the commune, he would be sent to prison and would stay there. Responses, summarized in
34 Table 13, show a sharp contrast between provinces. While the majority of respondents living in the
35 Central highlands (Antananarivo and Fianarantsoa) believe that the thief would be sent to jail,
36 respondents in other parts of the country -- most notably Antsiranana -- overwhelmingly believe the
37 thief would either not be convicted or, if convicted, would not serve his sentence.
38
39
40
41
42
43
44

45 These findings suggest that a major effort is long overdue to restructure and discipline the police
46 and especially the prison institutions in Madagascar. The main focus should be organized crime,
47 particularly cattle rustling. The evidence presented here indeed suggests that the insecurity
48 generated by crime, especially in remote rural areas, discourages economic activity and makes it
49 difficult to provide essential public services such as health care and schooling.

Table 1: Evolution of insecurity and welfare

Percentage of responses	Level of insecurity in commune	Evolution compared to five years ago				Infant mortality in commune
		Average income of inhab.	Health status of inhab.	School enrollment in commune		
Increased a lot	3%	10%	12%	14%	4%	
Increased a bit	27%	40%	61%	55%	20%	
Stayed the same	19%	15%	16%	14%	17%	
Decreased a bit	39%	28%	7%	12%	46%	
Decreased a lot	12%	7%	5%	4%	12%	
Total	100%	100%	100%	100%	100%	
No of valid observations	1379	1351	1349	1347	1294	

Table 2: Crime and insecurity statistics**A. Perceptions of insecurity by communal focus groups**

Percentage of responses	Level of insecurity in the commune
Very bad	9%
Bad	19%
Average	47%
Good	21%
Very good	4%
Total	100%
	Communes in 'red zone'
Yes=1	30%
	Stated first priority for development
1. Agriculture	27%
2. Roads	26%
3. Insecurity	15%
4. Health	14%
5. Education	10%
6. Water	6%
7. Environment	2%
Total	100%
No of valid observations	1379

B. Crime statistics

All figures reported in number of cases per year and per 100,000 inhabitants

	Mean	Median	Std. dev.
Number of stolen cattle	1496.0	62.0	5754
Number of stolen vehicles	0.2	0.0	2
Number of burglaries	42.8	7.9	97
Number of homicides	8.5	2.1	20
Number of rapes	2.9	0.0	10

C. Composition of focus groups

Average number of participants	8.6
Occupation:	
Communal employees	40%
Social/public service employees	21%
Village (fokontany) heads	6%
Farmers	14%
Others	19%

**Table 3: Link subjective and objective insecurity measures
ordered probit regression**

Crime	Unit	Coefficient	z-value
Comm. within "zone rouge"	yes=1	-1.001	-10.60
Number of stolen cattle annually	log(x+1)	-0.110	-7.91
Number of cars stolen annually	log(x+1)	0.001	0.00
Number of homicides annually	log(x+1)	-0.068	-2.19
Number of burglaries annually	log(x+1)	-0.089	-4.51
Number of rapes annually	log(x+1)	-0.035	-0.89
Composition of focus group			
size of the group	log(x)	0.022	0.17

Pseudo R2	0.0060		0.0117		0.0069		0.0063	

Each dependent variable takes values from 1 (worsened a lot) to 5 (improved a lot)

The insecurity variable takes values from 1 (improved a lot) to 5 (worsened a lot).

Table 5: Descriptive statistics for diseases and shocks

	Mean	Std. Dev
Climatic and agricultural shocks		
Cyclone	0.6	0.80
Flood	1.2	1.16
Broken bridge or cut road	1.2	1.29
Drought	1.0	1.17
Rice fleas	1.1	1.36
Phytopathological diseases	1.7	1.42
Frost	0.4	0.85
Locusts	0.8	0.87
Late start of rains	1.4	1.16
Human diseases		
Malaria	2.8	0.78
Tuberculosis	1.7	1.39
Typhoid	1.0	1.31
Cholera	0.5	0.83
Plague	0.3	0.77
Livestock diseases		
Distomatosis	2.5	1.07
Maladie du charbon bacterien	1.3	1.41
Maladie du charbon symptomatique	1.9	1.33
Pig plague	1.6	1.28
Newcastle disease (chicken)	2.7	0.87
Other livestock epidemic	0.7	1.22
Number of valid observations	1378	

Each variable measures the number of years the commune was affected by a shock or disease in the three years preceding the survey.

^{iv} After a disputed presidential election, the country was temporarily divided into two in early 2002, each faction occupying part of the island. After a blockade of the Central Highlands that lasted several months, the stand-off was eventually resolved when the incumbent president fled the country in June 2002. In spite of the severity of the political crisis, the level of political violence was kept surprisingly low, with estimates of crisis-related casualties numbering less than 100 victims.

^v The exact number remains unclear due to the existence of conflicting “official” lists. This confusion is the result of changes in the boundaries and composition of some communes in the mid-1990s.

^{vi} Nine communes were missed in the survey, either because they are too isolated or too insecure or both. The number of missing communes is very small so selection bias is unlikely to be an issue in the estimation.

^{vii} The high incidence of cattle rustling may be related to traditional practices of certain ethnic groups. The Bara, one of the dominant ethnic groups in Southwestern Madagascar, are known cattle thieves because young men are supposed to prove their manhood by stealing cattle. When they have done so, they are ready to get married (Ramiarantsoa, 1995). The Sakalava have similar customs. Cattle rustling is more common in the western part of the island. This largely reflects the fact that this drier part of the island is most suitable for extensive livestock production, which naturally facilitates livestock theft (Smith, Barrett and Box, 2001).

^{viii} It is conceivable that the feeling of insecurity responds more strongly to recent events. To investigate this possibility, we reestimate the model using only crime reported in the year preceding the survey (2001) and only crime reported in 1999. We obtain slightly stronger results (higher *t*-values) using 2001 crime data or the 1999-2001 average than using the 1999 numbers. But the results are otherwise quite similar.

^{ix} We omit malaria and two animal diseases -- distomatosis and Newcastle disease -- because they are endemic in the entire country and have too little variation for their coefficient to be identified. Including them does not change the conclusions regarding insecurity, however.

^x The regression by and large satisfies the balancing property. Balancedness is violated at the 5% level in two cases (out of a total of 24 variables times 7 blocks) involving two different variables in two different blocks, without any evidence of a pattern.

^{xi} It is also conceivable that the presence of young males coming of age during the period covered by our analysis had an worsening effect on crime and insecurity because crime (especially violent

1
2
3
4
5 crime) is often correlated with testosterone levels (Wilson, Daly and Pound, 2002). We would
6 expect this pattern in societies where crime is perpetrated by nearby residents, but it is unlikely to
7 apply to rural Madagascar where cattle rustling by itinerant gangs is the major security concern.

8 ^{xii} Unfortunately, we do not have longitudinal information on agricultural prices at the commune
9 level and cannot therefore test whether communes that became more insecure experienced a fall in
10 agricultural prices.

11 ^{xiii} For lowland cultivation, 3% of communes cited insecurity as the first reason for not expanding
12 acreage; another 7% cited it as second reason. For upland cultivation, insecurity was cited as first
13 and second reason by 8% and 15% of communes, respectively.

14 ^{xiv} It is not contended that service provision helps welfare. It is thus not really necessary for us to
15 demonstrate that a link exists in our data as well. The reader may nevertheless like to know that
16 when change in public provision is added to Table 8, results conform with expectations -- adding a
17 school raises school enrollment, adding agricultural input and output markets raises incomes, and
18 adding a health center tends to raise health status and reduce infant mortality. The latter effect,
19 however, is only significant at the 15 to 20% level.

20 ^{xv} This survey covered a sample of 150 communes and was undertaken in November 2002.
