ABSTRACT

1
2
3
4
5 The channels of the cobalt formate frameworks consist of one-dimensional channels that have a zig-zag
6 configuration. Propane (C3) has a length that is commensurate with the channel segment length; longer
7 n-alkanes such as n-butane (nC4), n-pentane (nC5) and n-hexane (nC6) have conformations that straddle
8 two channels segments. Configurational-bias Monte Carlo (CBMC) simulations show that the
9 adsorption strength of C3 is higher than that of n-butane (nC4), and n-pentane (nC5); this unusual
10 hierarchy is a direct consequence of commensurate – incommensurate adsorption. CBMC simulations
11 also reveal the possibility of separating C3-nC6, C3-nC4, nC4-nC6, nC4-nC5 *liquid* mixtures for which
12 the adsorbed phase contains predominantly the *shorter* alkane. Molecular dynamics (MD) simulations
13 show that the hierarchy of self-diffusivities is non-monotonic and is the mirror image of the hierarchy of
14 adsorption strengths.

1. Introduction

In recent years there has been a remarkable upsurge in research activity on metal-organic frameworks (MOFs), in view of several potential applications in the field of storage [1-4], and also separation of a variety of mixtures [5-21]. Due to the wide variety of pore sizes, and pore geometries a number of interesting separation possibilities are possible with MOFs. For example, Finsky et al.[11] have reported a significantly higher adsorption capacity for xylene isomers in MIL-47, than for its isomers, n-octane (nC8) and ethyl benzene (EtBz). The higher capacity for xylene isomers is due to their improved “stacking efficiency” within the channels of MIL-47, as illustrated in the snapshots in Figures 1a, and 1b for *p*-xylene and nC8 respectively; see also the pure component isotherms in Figure 2. Bárcia et al.[7] report the results of an experimental study to show the feasibility of separating alkane isomers by adsorption within the framework of Zn(bdc)dabco (see structure in Figure 3). In a subsequent study, Dubbeldam et al. [21] have used molecular simulations have shown that the principle behind alkane isomers separation using Zn(bdc)dabco framework is based on the differences in “efficiency” with which the isomer molecules can interact with the dabco linker atoms.

The current investigation focuses on another unusual separation potential of MOFs and has its genesis in the recent work by Li et al.[22], that reported adsorption isotherms for n-alcohols in cobalt formate (Co-FA) framework structure. The metal network exhibits diamondoid connectivity and the overall framework gives rise to zig-zag channels along the *b* axis where guest dimethylformamide molecules reside. The effective pore size of these one-dimensional channels is 5 – 6 Å. The unit cell and pore landscape of Co-FA is depicted in Figure 4; one unit cell of Co-FA comprises a total of four distinct channel “segments”; each channel segment forms part of the repeat zig-zag structure. The experimental adsorption data of Li et al.[22] for propanol and n-butanol in Co-FA, are particularly intriguing; see Figure 5. We note that the adsorption strength of propanol is higher than that of n-butanol over the entire range of experimental pressures. The first major objective of the present communication is to show,

1 with the help of molecular simulations, that this unusual hierarchy in adsorption strengths is caused by
2 commensurate-incommensurate molecular lengths of linear molecules within the one-dimensional
3 channels of Co-FA. For this purpose we have carried out a set of Configurational-bias Monte Carlo
4 (CBMC) simulations to determine the adsorption isotherms of linear alkanes: methane (C1), ethane
5 (C2), propane (C3), n-butane (nC4), n-pentane (nC5), n-hexane (nC6), and n-heptane (nC7) in Co-FA.
6
7 The second objective is to demonstrate the exploitation of commensurate-incommensurate molecular
8 lengths to adsorb a *shorter* linear alkane preferentially from a liquid mixture with a longer linear alkane.
9
10 The third objective, using Molecular Dynamics (MD) diffusion of n-alkanes in Co-FA, is to show that
11 the non-monotonous hierarchy of adsorption strengths is accompanied by a non-monotonous hierarchy
12 in diffusivities.

25 2. Simulation details

26
27 The structural information for Co-FA is from Li et al. [22]. The adsorption isotherms were computed
28 using Configurational-bias Monte Carlo (CBMC) simulations in the grand canonical (GC) ensemble.
29
30 The united atom force field for alkanes, developed by Dubbeldam et al. [23], is used to describe alkane-
31 alkane, Lennard-Jones, interactions. For alkane-alkane interactions the tabulated force fields are
32 available in Dubbeldam et al. [23]; the potential for the n-alkanes includes bond stretching, bending, and
33 torsion. The framework was assumed to be rigid in the simulations.
34
35
36
37
38
39
40

41 For the atoms in the guest metal organic framework, the generic UFF [24] was used. The DREIDING
42 [25] force fields was used for the organic linker atoms. The Lorentz-Berthelot mixing rules were applied
43 for calculating σ and ε/k_B for guest-host interactions.
44
45
46
47

48 Further simulation details, including structural information, CBMC and MD simulation
49 methodologies, tabulated force fields, pore landscapes, snapshots showing the location and
50 conformation of n-alkanes within the pores, and simulation data are available in the Supplementary
51 material accompanying this publication.

3. Adsorption of linear alkanes in Co-FA

1
2
3 Consider the CBMC simulations of the adsorption isotherms of linear alkanes in Co-FA at 300 K; see
4
5 Figure 6a. The hierarchy of adsorption strengths for C1, C2 and C3 is as expected; increasing chain
6
7 length results in a higher adsorption strength; see Henry coefficient data in Figure 6b. However, with
8
9 increasing chain lengths beyond C3 we note an unusual adsorption hierarchy: $C3 > nC4 > nC5$. Further
10
11 increase in chain length, results in the expected hierarchy, i.e. $nC7 > nC6 > nC5$. The saturation capacity
12
13 for C1, C2, and C3 is found to be 4 molecules per unit cell, corresponding to one molecule per channel
14
15 segment. Snapshots of the location of molecules along the 1D zig-zag channels of Co-FA confirm that
16
17 each channel segment contains no more than one molecule each of C1, C2 and C3; see Figure 7. $nC5$,
18
19 $nC6$ and $nC7$ have conformations that make these molecules straddle two channel segments, and this is
20
21 also reflected in the saturation capacities of these molecules of 2 molecules per unit cell, i.e.
22
23 corresponding to 1 molecule in two channel segments. $nC4$ has an intermediate character; at low
24
25 pressures the $nC4$ has a conformation with a tendency to occupy a small portion of the adjoining
26
27 segment. At very high pressures, $nC4$ adopts a more “cramped” configuration, with each molecule
28
29 occupying one channel segment and yielding a saturation capacity of 4 molecules per unit cell. When a
30
31 molecule has a tendency to straddle two channel segments ($nC4$ at low pressures, $nC5$, $nC6$, and $nC7$)
32
33 not all of the C atoms can effectively interact with the atoms of the framework; this leads to a lower
34
35 adsorption strength and a non-monotonous adsorption hierarchy witnessed in the Henry coefficient data
36
37 in Figure 6b. It is interesting to note that non-monotonous behaviour of the Henry coefficient for n-
38
39 alkanes has also been observed for cage-type zeolites such as CHA, ERI and LTA, caused by
40
41 commensurate – incommensurate adsorption within cages [26-28].
42
43
44
45
46
47
48

49
50 The non-monotonous adsorption characteristics, along with differences in saturation capacities can be
51
52 exploited to achieve unusual separation possibilities. Consider a mixture of C3 and $nC6$. From the pure
53
54 component adsorption isotherms in Figure 6 we note that at low pressures the adsorption strengths of C3
55
56 is nearly the same as that of $nC6$. However the saturation capacity of C3 is twice that of $nC6$. We can
57
58 devise a strategy for separating C3 from $nC6$ by exploiting the differences in the saturation capacities.
59
60

1 CBMC simulations of the component loadings for a mixture with equal partial fluid phase fugacities, $f_1 =$
 2 f_2 , are shown in Figure 8a. When operating at partial fugacities in excess of 1 MPa, with a bulk *liquid*
 3 phase, we note that the adsorbed phase contains practically no nC6 and is predominantly C3.
 4
 5

6
 7 Analogously for nC4-nC5 liquid mixtures, the adsorbed phase contains the shorter alkane, almost
 8 exclusively; see Figure 8b. For C3-nC4, and nC4-nC6 mixtures the separation is somewhat less
 9 selective. The CBMC simulations results in Figure 9 show that at high loadings, the adsorbed phase is
 10 not exclusively the shorter alkane but also contains a small proportion of the longer alkane. The
 11 separations indicated in Figures 8 and 9 have possible industrial potential, and needs to be
 12 experimentally confirmed. It is perhaps relevant to point out here that we had earlier used molecular
 13 simulations to demonstrate the feasibility of separating n-alkane mixtures by exploiting differences in
 14 the saturation capacity in cage-type zeolites such as CHA, ERI, and AFX zeolites [29]. More recently
 15 the experimental work of Denayer et al.[30] has provided experimental confirmation of the separation
 16 potential anticipated by the molecular simulations.

32 **4. Diffusion of linear alkanes in Co-FA**

33
 34 MD simulations of self-diffusivities of C1, C2, C3, nC4, nC5, nC6 and nC7 in Co-FA are shown in
 35 Figure 10a for a variety of loadings. At a loading of 1 molecule per unit cell, the values of the
 36 selfdiffusivities are plotted in Figure 10b as a function of C number. The hierarchy of diffusivities of C1,
 37 C2, and C3 is as expected; the molecule with the longer chain length has the lower diffusivity. With
 38 increasing chain length we observe a non-monotonous behavior with the hierarchy: nC5 > nC4 > C3 ≈ nC6.
 39 The hierarchy of diffusivities is an exact mirror image of the hierarchy of Henry coefficients; compare
 40 Figures 6b and 10b. Put another way, if the molecular length is incommensurate with the channel
 41 segment length, the adsorption strength is low, but its diffusivity is high.
 42
 43
 44
 45
 46
 47
 48
 49
 50
 51
 52

53 In the context of separation process development, it must be emphasized that since adsorption and
 54 diffusion run counter to each other, we should aim for either an equilibrium based separation or a
 55
 56
 57
 58
 59
 60

1 diffusional (i.e. kinetic) based separation. A combination of the two, for example, in a MOF membrane
2 separation will not work, as the two effects may cancel each other out.
3
4
5
6
7

8 **5. Conclusions**

9
10 CBMC and MD simulations of adsorption and diffusion of linear alkanes within the one-dimensional
11 channels of cobalt formate frameworks have revealed a non-monotonic behavior in Henry coefficients
12 and diffusivities as a function of the n-alkane chain length. The non-monotonicity is caused due to
13 commensurate – incommensurate effects in adsorption; C3 has a molecular length that is commensurate
14 with the channel segment length. nC4, nC5, nC6 and nC7 have conformations that make these
15 molecules straddle two channel segments; this leads to a lower adsorption strength due to inefficient
16 interaction with the framework atoms. The hierarchy of diffusivities is inverse of the hierarchy of
17 adsorption strengths.
18
19
20
21
22
23
24
25
26
27
28

29 CBMC simulations also reveal the possibility of separating C3-nC6, C3-nC4, nC4-nC6, nC4-nC5
30 *liquid* mixtures for which the adsorbed phase contains predominantly the *shorter* alkane.
31
32
33

34 Manganese formate frameworks are iso-structural to Co-FA, and a similar non-monotonicity in
35 adsorption and diffusion behaviour is observed from molecular simulations; details are available in the
36 supplementary material.
37
38
39

40 Our study underlines the ability of molecular simulations to provide a molecular level understanding
41 of observed experimental phenomena, and also to unravel novel separations with structured nanoporous
42 materials such as MOFs.

Supplementary Material to accompany:

A molecular simulation study of commensurate –
incommensurate adsorption of n-alkanes in cobalt
formate frameworks

R. Krishna*, J.M. van Baten

Appendix A: Molecular Simulation methodology and simulation results

1. MOF structures

Besides Cobalt Formate frameworks, simulations were also carried out for Manganese Formate (Mn-FA), Zn(bdc)dabco, and MIL-47. The structural information for the metal organic frameworks have been taken from various publications on the respective frameworks: Cobalt Formate (Co-FA) from Li et al. [1]; Manganese Formate (Mn-FA) from Dybtsev et al. [2]; Zn(bdc)dabco from Barcia et al.[3] and Lee et al. [4]; MIL-47 from Alaerts et al. [5], Finsy et al. [6] and Barthelet et al. [7]. The structure data files we used in our simulations are available on our website [8].

2. Monte Carlo simulation methodology

The adsorption isotherms were computed using Configurational-bias Monte Carlo (CBMC) simulations in the grand canonical (GC) ensemble. The united atom force field for alkanes, developed by Dubbeldam et al. [9], is used to describe alkane-alkane, Lennard-Jones, interactions. For alkane-alkane interactions the tabulated force fields are available in Dubbeldam et al. [9]; the potential for the n-alkanes includes bond stretching, bending, and torsion. Some simulation results have also been reported for aromatics and alkyl-aromatics in MIL-47. The force field for benzene follows the work of Ban et al.[10], and extended to alkyl aromatics by combining with the force field of Dubbeldam et al. [9].

The metal organic framework structures of Co-FA, Mn-FA, Zn(bdc)dabco, and MIL-47 were considered to be rigid in the simulations. For the atoms in the guest metal organic framework, the generic UFF [11] was used. The DREIDING [12] force fields was used for the organic linker atoms. The Lennard-Jones parameters are summarized in Table 1. The Lorentz-Berthelot mixing rules were

1 applied for calculating σ and ϵ/k_B for guest-host interactions. For simulations with linear and branched
2 alkanes with two or more C atoms, the Configurational-Bias Monte Carlo (CBMC) simulation
3 technique [13, 14] was employed. The beads in the chain are connected by harmonic bonding potentials.
4
5 A harmonic cosine bending potential models the bond bending between three neighboring beads, a
6 Ryckaert-Bellemans potential controls the torsion angle. The beads in a chain separated by more than
7 three bonds interact with each other through a Lennard-Jones potential. The Lennard-Jones potentials
8 are shifted and cut at 12 Å. The CBMC simulation details have been given in detail elsewhere [9, 13-
9 15]. The CBMC simulations were performed using the BIGMAC code developed by T.J.H. Vlugt[16]
10 as basis.

23 3. MD simulation methodology

24
25 Diffusion of linear alkanes in Co-FA and Mn-FA were investigated and simulated using Newton's
26 equations of motion until the system properties, on average, no longer change in time. The Verlet
27 algorithm is used for time integration. A time step of 1 fs was used in all simulations. For each
28 simulation, *initializing* CBMC moves are used to place the molecules in the domain, minimizing the
29 energy. Next, follows an *equilibration* stage. These are essentially the same as the production cycles,
30 only the statistics are not yet taken into account. This removes any initial large disturbances in the
31 system that do not affect statistics on molecular displacements. After a fixed number of initialization
32 and equilibrium steps, the MD simulation *production* cycles start. For every cycle, the statistics for
33 determining the mean square displacements (MSDs) are updated. The MSDs are determined for time
34 intervals ranging from 2 fs to 1 ns. In order to do this, an order- N algorithm, as detailed in Chapter 4 of
35 Frenkel and Smit[13] is implemented. The Nosé-Hoover thermostat is applied to all the diffusing
36 particles.

52 The DLPOLY code[17] was used along with the force field implementation as described in the
53 previous section. DL_POLY is a molecular dynamics simulation package written by W. Smith, T.R.
54 Forester and I.T. Todorov and has been obtained from CCLRCs Daresbury Laboratory via the
55 website.[17]
56
57
58
59
60

The MD simulations were carried out for a variety of molecular loadings. All simulations were carried out on the LISA clusters of PCs equipped with Intel Xeon processors running at 3.4 GHz on the Linux operating system[18]. Each MD simulation, for a specified loading, was run for 120 h, determined to be long enough to obtain reliable statistics for determination of the diffusivities. In many cases, several independent MD simulations were run and the results averaged.

The self-diffusivities, $D_{i,self}$, were computed by analyzing the mean square displacement of each species i for each of the coordinate directions:

$$D_{i,self} = \frac{1}{2n_i} \lim_{\Delta t \rightarrow \infty} \frac{1}{\Delta t} \left\langle \left(\sum_{l=1}^{n_i} (\mathbf{r}_{l,i}(t + \Delta t) - \mathbf{r}_{l,i}(t))^2 \right) \right\rangle \quad (1)$$

In this expression n_i represents the number of molecules of species i respectively, and $\mathbf{r}_{l,i}(t)$ is the position of molecule l of species i at any time t . For one-dimensional pore structures of Mn-FA, and Co-FA, the diffusivities along the y-direction of diffusion are reported.

4. Animations

For visual appreciation of the diffusion phenomena in Co-FA, Mn-FA, Zn(bdc)dabco, and MIL-47, animations were created on the basis of the MD simulations; these can be viewed by downloading the movies from our website[8].

5. Simulation results for Co-FA

Figures 1 to 10 present the pore landscapes, and snapshots of n-alkanes in Co-FA. The simulation results, summarized in Figure 11, have been discussed in the main text of the paper.

6. Simulation results for Mn-FA

Figures 12 to 21 present the pore landscapes, and snapshots of n-alkanes in Mn-FA. The simulation results for adsorption of n-alkanes. As with Co-FA, the adsorbed phase is predominantly the shorter alkane. The near-complete separation of the nC4-nC5 mixture at high loadings is particularly

1 noteworthy. The diffusivity data for n-alkanes is summarized in Figure 22. Again we note the non-
2 monotonicity as for Co-FA.
3
4
5

6 **7. Simulation results for MIL-47**

7
8 Figures 24 to 32 present the pore landscapes, and snapshots for xylenes, nC8, ethyl benzene and
9 benzene within the channels of MIL-47. In Figure 33 the CBMC simulations of the pure component
10 isotherms for C8 isomers are compared with the experimental results of Finsy et al. [6]. There is
11 reasonably good agreement in the saturation capacities and the results indicate the possibility of
12 separating C8 hydrocarbon isomers using differences in “stacking” efficiency within the channels of
13 MIL-47.

20
21
22
23

24 **8. Simulation results for Zn(bdc)dabco**

25
26 Figures 34 to 45 present the pore landscapes, and snapshots of a variety of alkanes in Zn(bdc)dabco.
27 Pure component, and ternary, CBMC simulations of the isotherms for nC6, 3MP, and 22DMB are
28 present in Figure 46. The simulations at 300 K are in good agreement with the simulation results of
29 Dubbeldam et al. [19]. Also shown in Figure 46 are the comparisons of the pure component isotherms
30 for hexane isomers at 313 K obtained from CBMC simulations (top right) with the experimental data of
31 Bárcia et al. [3] (bottom right). The agreement is very poor. We suspect that in the experiments the
32 Zn(bdc) dabco structure must have undergone phase transition because the reported experimental
33 loadings are about one order of magnitude lower than the usual loading values found for MOFs.
