Abstract

21
22 *Lactobacillus* sp. are important inhabitants of the intestines of animals. They are also largely
23 used as probiotics for both humans and animals. To exert beneficial effects, lactobacilli have
24 to survive through the gastrointestinal transit. Based on bile-salt resistance, pH tolerance,
25 antimicrobial activity and heat resistance, *Lactobacillus plantarum* 4.1 and *Lactobacillus*
26 *reuteri* 3S7 were previously selected and used as probiotic additives in pelleted feeding trials.
27 Both strains were fed to pigs (sows and piglets) at a cell number of ca. 10^{10} viable cells per
28 days. A polyphasic approach, comprising growth on selective media, Biolog system analysis,
29 16S rRNA gene sequencing and RAPD-PCR typing, was used to identify and differentiate *L.*
30 *plantarum* 4.1 and *L. reuteri* 3S7 from other faecal *Lactobacillus* sp. *L. plantarum* 4.1 and *L.*
31 *reuteri* 3S7 had the capacity to survive the gastrointestinal transit and were found in the
32 faeces at a cell number of 6 to 8 log cfu/g. Their persistence was shown after six days from the
33 administration. Compared to untreated pigs, the administration of *L. plantarum* 4.1 and *L.*
34 *reuteri* 3S7 significantly ($P < 0.05$) decreased the population of *Enterobacteriaceae*. Besides, the
35 β -glucuronidase activity of all pigs decreased of ca. 23.0% during administration. The
36 findings of this study showed that *L. plantarum* 4.1 and *L. reuteri* 3S7 have the potential to be
37 used as probiotic additives in pelleted feed for pigs.

41 1. Introduction

42 Oedema and diarrhea caused by pathogenic *Escherichia coli* are common diseases of piglets,
43 especially during early weaning (Beutin et al., 1998). These diseases may result in considerable
44 economic losses for the pig rearing industry. Intestinal carriage of enteropathogens (e.g., *Salmonella*
45 and *Yersinia*) by farm animals might determine carcass contamination during slaughtering and,
46 subsequently, their transmission to humans. An important concern in pig breeding is represented by
47 *Salmonella* infection from sows to piglets (Osterberg et al., 2001; Nollet et al., 2005). Overall,
48 treatments with antibiotics (e.g. enrofloxacin) failed to prevent shedding by *Salmonella enterica*
49 serovar *Typhimurium* in pig farms, causing the further infection of piglets (Roesler et al., 2005).
50 Pregnant sows and young pigs may be subjected to stressful physiological and environmental
51 conditions which promote the proliferation of pathogens in the digestive tract. Since most of the
52 antibiotics used as growth promoters in pig feeding have been banned by European laws, alternative
53 strategies to favor the prevalence at gastrointestinal tract (GIT) of useful indigenous bacteria
54 towards pathogens are needed (Wegener et al., 1999). As a consequence, the pig diet is considered
55 as a crucial point to prevent enteric bacterial infections (Bach Knudsen, 2001).

56 Probiotics are described as ‘live micro-organisms which when administered in adequate
57 numbers confer a health benefit on the host’. The prevention of GIT pathogen colonization through
58 competitive exclusion, and/or synthesis of inhibitory compounds (Kaur et al., 2002; Isolauri et al.,
59 2004) is the primary mechanism mediated by probiotics (Forestier et al., 2001; Lu and Walker,
60 2001). However, commercially available probiotic-based products have been of variable efficacy,
61 and in most cases retailing has preceded scientific validation. Probiotic bacteria may be effective in
62 promoting good health when they reach the small and large intestines without loss of viability.
63 Overall, it has been shown that probiotic bacteria vary considerably in the tolerance of bile and
64 other GI conditions. Therefore, *in vivo* challenges are indispensable to show the capacity to survive
65 after the GI transit (Lick et al., 2001). As shown in several reports (Alander et al., 1999; Fujiwara et
66 al., 2001; Ohashi et al., 2001; Gardiner et al., 2004), the survival of administered probiotics is

67 determined based on their recovery as viable cells from faeces (Alander et al., 1999; Fujiwara et al.,
68 2001; Ohashi et al., 2001; Gardiner et al., 2004).

69 This study aimed at investigating the *in vivo* performance of *L. plantarum* 4.1 and *L. reuteri*
70 3S7 orally administered to pigs. The two strains were previously isolated from porcine faeces and *in*
71 *vitro* characterized for their technological (resistance to freeze-drying and heating) and probiotic
72 (bile-salt and low pH tolerance, inhibition of pathogen *E. coli* causing diarrhea and edema disease,
73 and *S. enterica* serovar *Typhimurium*) potentialities (De Angelis et al., 2006).

74

75 **2. Materials and methods**

76

77 *2.1. Micro-organisms and growth conditions*

78 The lactic acid bacteria used in this study were *L. plantarum* 4.1 and *L. reuteri* 3S7 and belong to
79 the Culture Collection of Department of Plant Protection and Applied Microbiology of the
80 Agriculture Faculty, University of Bari, Italy. The strains, isolated from pig faeces of Large White
81 sows, were previously characterized by *in vitro* assays for bile-salt resistance, pH tolerance,
82 antimicrobial activity, freeze-drying and heat resistance (De Angelis et al., 2006). Bacteria were
83 anaerobically grown over night at 37 °C in MRS (Oxoid Ltd., Basingstoke, Hampshire, England)
84 medium (4% inoculum) from glycerol (20% v/v) stocks stored at -80 °C. After growth, lactic acid
85 bacteria were harvested by centrifugation (8000 × g for 10 min), washed twice with 50 mM sterile
86 potassium phosphate buffer (pH 7.0), lyophilized and used as additives for pellet diet.

87

88 *2.2. Experimental diet*

89 The commercial pig diet had the following composition (w/w): 55% maize, 27% soya, 8.4%
90 barley, 4% wheat bran, 3% fat, 1.2% CaPO₄, 1% CaCO₃ and 0.4% NaCl. The feed (1.5 kg) was
91 mixed and gently homogenized with 5% (w/w) of water and 1% (w/w) of lyophilized cells of

92 lactobacilli mix (10 log cfu/g). The mixture was pelleted by a Baby-IEMME equipment (IEMME,
93 Verona, Italy) at 55-60 °C for 30-40 s. Final moisture of the pelleted diet was ca. 16% (w/w).

94

95 2.3. Pig-feeding trials

96 Seven pregnant sows and four piglets (two males and two females) of the Large White breed
97 were used for feeding trials. Four additional animals (two sows and two piglets) were included in
98 the study as the control and were not subjected to treatment with lactobacilli. The pig-feeding trial
99 complied with European Union Council Directive 91/630/EEC, which lays down minimum
100 standards for the protection of pigs. In order to avoid cross-contaminations, each animal was
101 individually penned. All animals had unrestricted access to water. Diets used for 15 days before
102 starting the trial did not contain antimicrobials, performance enhancers, probiotics or acidifiers. The
103 feeding trial consisted of three consecutive periods: baseline (10 days), lactobacilli administration
104 (15 and 70 days for piglets and sows, respectively), and post-administration (6 days). During
105 baseline each sow and piglet received 500 g of pelleted diet per day and other un-pelleted feed.
106 During lactobacilli administration, a total of ca. 10 log cfu of lactobacilli were provided daily to
107 each pig by supplying 500 g of pelleted feed which contained ca. 7.1 log cfu/g of each
108 *Lactobacillus* strain. During post-administration, pigs did not ingest lactobacilli. Control pigs were
109 fed with a basal diet without *Lactobacillus* strains.

110

111 2.4. Microbiological analysis of pig faecal samples, and identification and typing of probiotic 112 strains

113 Rectal samples of faeces were obtained for each animal prior, during and after lactobacilli
114 administration. After collection, faeces (ca. 5 g) were mixed with Amies Transport medium (Oxoid)
115 under anaerobic conditions. Subsequently, samples were suspended in quarter-strength Ringer's
116 solution, homogenized with a classic blender (PBI International, Milan, Italy) and plated on MRS
117 agar at 30 °C for 48 h. MRS, containing 150 µg/ml of chloramphenicol or streptomycin as selective

118 agents, was also used (De Angelis et al., 2006). Representative colonies were randomly picked up
119 from plates of MRS or MRS, containing chloramphenicol or streptomycin, and were subjected to
120 16S rRNA, PCR-RAPD and Biolog system analyses (Biolog, Inc., Hayward, CA, USA). Faecal
121 bacteria of the family *Enterobacteriaceae* were enumerated on Violet Red Bile Glucose Agar
122 (VRBA, Oxoid) at 37 °C for 24 h under anaerobic conditions (Gardiner et al., 2004).

123

124 *2.4.1. Genotypic identification of lactic acid bacteria.* Total DNAs from Gram-positive, catalase-
125 negative and non-motile presumptive lactobacilli were extracted from 2 ml of overnight cultures
126 grown in MRS and incubated anaerobically at 37 °C. The final concentration of lysozyme used for
127 cell lysis was 2 mg/ml. The concentration and purity of DNA were assessed by determining the
128 absorbance at 260 and 280 nm. Primers used to amplify 16S rRNA gene fragment of lactobacilli are
129 listed in Table 1. Fifty microliters of each polymerase chain reaction (PCR) mixture contained: 5 µl
130 of 10 x PCR buffer, 200 µM of each 2'-deoxynucleoside 5'-triphosphate (dNTPs), 1 µM of both
131 forward and reverse primer, 2 mM MgCl₂, 2 U of *Taq* DNA polymerase (Invitrogen Life
132 Technologies, Milan, Italy), ca. 50 ng of DNA and enough bidistilled water to reach the final
133 volume. PCRs were performed using the GeneAmp PCR System 9700 thermal cycler (Applied
134 Biosystems, Foster City, CA, USA) as reported by De Angelis et al. (2006). PCR products were
135 separated by electrophoresis on 1.5% (w/v) agarose gel (Gibco BRL, Eragny, France) stained with
136 ethidium bromide (0.5 µg/ml), and the DNA was detected by UV transillumination. The expected
137 amplicons were excised from the gel and purified by the GFXTM PCR DNA and Gel Band
138 Purification Kit (Amersham Biosciences, Piscataway, NJ, USA). DNA sequencing reactions were
139 performed by MWG Biotech AG (Ebersberg, Germany). The identities of the sequences, obtained
140 after analysis of amplified PCR products, were verified by a BlastN search against the NCBI non-
141 redundant sequence database located at <http://www.ncbi.nlm.nih.gov>. Strains showing homology of
142 at least 97% were considered to belong to the same species.

143

144 *2.4.2. Genotypic characterization by RAPD.* Isolates from pig faeces were characterized genotypically
145 by RAPD-PCR analysis. Four primers (Table 1) with arbitrarily chosen sequences were used. The
146 reaction mixture for primer M13 contained: 25 ng of DNA, MgCl₂ 1.5 mM, 20 μM of primer, 200 μM
147 for each 2'-deoxynucleoside 5'-triphosphate, 2.5 μl of PCR buffer (10x), 1.25 U of *Taq* DNA
148 polimerasi (Invitrogen Life Technologies) and enough sterile bidistilled water to bring the volume to 25
149 μl. The PCR program comprised 40 cycles of denaturation for 1 min at 94 °C, annealing for 20 sec at 35
150 °C, and extension for 2 min at 72 °C. The cycles were preceded by denaturation step at 94 °C for 2 min
151 and followed by extension step at 72 °C for 10 min. The other primers were used in the same conditions
152 described by De Angelis et al. (2001). PCR products were separated by electrophoresis at 120 V for 3 h
153 on 1.5% (w/v) agarose gel as above reported. Molecular sizes of the amplified DNA fragments were
154 estimated by comparison with a 1 Kb plus ladder DNA (Invitrogen Life Technologies). Gels were
155 acquired using a UNIsave gel documentation system camera, Model GAS9200/1/2/3, Version 11
156 (UVItec Limited, Cambridge, United Kingdom). Electrophoretic profiles were compared using Quantity
157 One software (Biorad, Milan, Italy).

158

159 *2.4.3. Fermentative profile by Biolog System.* Three days before the inoculation of Biolog AN plates
160 (Biolog, Inc.), the strains were streaked twice on MRS agar plates. The plates were incubated at 30
161 °C for 24 h and thereafter cells were used for Biolog assays. Wells of Biolog AN plates were
162 inoculated with 150 μl of bacterial suspensions adjusted to 65% transmittance as recommended by
163 the manufacturer. Positive reactions were automatically recorded using a microplate reader with
164 590 nm wavelength filter.

165

166 *2.5. β-glucuronidase activity*

167 β-glucuronidase activity (EC 3.2.1.31) was determined as described by Haberer et al. (2003),
168 using *p*-nitrophenyl-β-D-glucuronide (Diffchamb, Sweden) as substrate. The assay mixture,
169 containing 0.085 M potassium phosphate buffer at pH 7.5, 0.015 M substrate, 0.031 M 3,4-

170 dichloronitrobenzene, and 0.5 ml of faecal suspension, was incubated at 30 °C for 48 h under
171 anaerobic and stirring conditions (150 rpm). After incubation, the absorbance of the mixture was
172 measured at 402 nm. One unit (U) of activity was defined as the amount of enzyme required to
173 release 1 μ mol of *p*-nitrophenol per 10 min under condition assay. Data obtained were compared to
174 standard curves set up by using *p*-nitrophenol.

175

176 2.6. Statistical analyses

177 Data from three independent replicates were subjected to one-way ANOVA (SAS, 1985); for
178 multiple comparison the Tukey test was used and the alpha value for all experiments was set at
179 0.05, using a statistical software, Statistica for Windows (Statistica 6.0 per Windows 1998).

180

181 3. Results

182 3.1. Performance of animals

183 No antibiotics were fed during the period of investigation period as well as no particular feed
184 composition was needed. All the sows and piglets remained healthy throughout the duration of the
185 experiments and no cases of diarrhea were observed.

186 3.2. Enumeration and identification of lactobacilli in pig faeces

187 As determined by plate counts, the pig faeces of the 7 Large White sows had similar cell numbers
188 of presumptive lactobacilli which ranged from 8.88 to 9.11 log cfu/g (Fig. 1). Presumptive
189 lactobacilli were isolated at the same order of magnitude (8.67 to 9.11 log cfu/g) from the faeces of
190 the control group during 70 days. No significant changes in the cell number of presumptive
191 lactobacilli were found throughout the whole feeding period: it was constant in the range 8.99 –
192 9.13 log cfu/g.

193 Lactobacilli were detected in piglets (5.85 – 6.25 log cfu/g) at a cell number 2 – 3 log cycles lower
194 than adult animals (8.88 – 9.11 log cfu/g). During the 15 days of treatment, lactobacilli raised to

195 7.87 log cfu/g within 3 days and further increased to ca. 8.5 log cfu/g for the remaining time (Fig.
196 2). After 3 and 6 days of post-administration the cell number of lactobacilli decreased of ca. 1 log
197 cycle (7.84 and 7.54 log cfu/g, respectively) but was still significantly ($P<0.05$) higher than the
198 value determined in the control group. Fifteen Gram-positive, catalase-negative, non-motile and
199 acidifying isolates of presumptive lactobacilli were randomly picked up from the plates of the
200 highest sample dilution and subjected to preliminary group differentiation based on several
201 physiological characters. All isolates with different characters (Biolog and/or RAPD profiles) were
202 identified based on partial sequencing of the 16S rRNA gene. All sequences were deposited in
203 GenBank database and the accession numbers were: EF439669 – EF439675; EF439676 –
204 EF439684; EF439685 – EF439689; EF439690 – EF439696; EF439697 – EF439704 and EF439705
205 – EF439706 for *L. reuteri*, *L. plantarum*, *Lactobacillus crispatus*, *Lactobacillus mucosae*,
206 *Lactobacillus amylovorus* and *Lactobacillus intestinalis* strains, respectively. The partial 16S rRNA
207 gene sequences of *L. reuteri* 3S7 (AY823503) and *L. plantarum* 4.1 (AY845198) were deposited
208 previously. The endogenous species of *Lactobacillus* identified in the pigs subjected to lactobacilli
209 administration did not differ from those detected in the control groups. The *Lactobacillus*
210 microbiota did not differ between sows and piglets.

211

212 3.3 Survival and persistence of administered strains.

213 As previously described (De Angelis et al., 2006), *L. reuteri* 3S7 was sensitive to chloramphenicol
214 and resistant to streptomycin while *L. plantarum* 4.1 was sensitive to streptomycin but resistant to
215 chloramphenicol. As a consequence, MRS containing chloramphenicol or streptomycin was used to
216 differentiate in faecal samples the administrated strains. Prior to lactobacilli administration, 4.5 –
217 5.0 and 5.1 – 6.0 log cfu/g of lactobacilli resistant to chloramphenicol or streptomycin, respectively,
218 were determined in faecal samples. After 3 and 7 days, all pigs subjected to lactobacilli
219 administration excreted 6.4 to 7.0 log cfu of chloramphenicol and streptomycin resistant lactobacilli
220 per gram of faeces and similar cell densities (6.8 – 8.2) were found throughout the remaining period

221 (data not shown). Fifteen Gram-positive, catalase-negative, non-motile and acidifying isolates of
222 presumptive lactobacilli were randomly picked up from the plates of the highest sample dilution and
223 subjected to RAPD-PCR analysis by using single primers P1, P4, P7 or MI3. The reproducibility of
224 RAPD fingerprints was assessed by comparing the PCR products obtained from three separate
225 cultures of the same strain. The patterns showed ca. 92 – 95% similarity, indicating the
226 reproducibility of the technique under the conditions used (data not shown). RAPD-PCR analysis
227 allowed the identification of the two lactobacilli administrated once re-isolated from faecal samples.
228 Fig. 3 shows the RAPD-PCR fingerprints, generated with primer MI3, of most of the representative
229 faecal isolates which differed from the administrated strains. To further confirm the presence of *L.*
230 *plantarum* and *L. reuteri* in faecal samples of treated pigs, the isolates were analysed by Biolog
231 System also. Table 2 shows the fermentative profiles of some of the isolates of the *L. plantarum* and
232 *L. reuteri* species. Prior to culture administration, none of the two administrated strains was
233 detected in the faeces of any pigs (Table 3). In the same way, *L. plantarum* 4.1 and *L. reuteri* 3S7
234 were not detected in the control groups (sows and piglets numbered 1-2). During administration, the
235 recovery of *L. plantarum* 4.1 and *L. reuteri* 3S7 was relatively high (ca. 4 strains out of 15 total
236 lactobacilli). After 6 days from the treatment, the two lactobacilli strains were still detected in the
237 sow faeces. The recovery of *L. plantarum* 4.1 and *L. reuteri* 3S7 in the piglet faeces was higher than
238 that in sow faeces; a maximum of 7 strains out of 15 total lactobacilli was detected after twelve
239 days. Re-isolation of *L. plantarum* 4.1 and *L. reuteri* 3S7 from faeces of both sows and piglets was
240 less frequent during the washout period.

241

242 3.4. Effects on intestinal microbiota

243 The enumeration of *Enterobacteriaceae* in faeces was carried out since this group of Gram-negative
244 bacteria is indicative of the presence of pathogenic species such as *E. coli* and *Salmonella* sp.
245 (Gardiner et al., 2004). The cell number of *Enterobacteriaceae* excreted in sow and piglet faeces
246 during lactobacilli administration and post-administration is shown in Figs. 4 and 5. The averaged

247 number of *Enterobacteriaceae* in the sow faeces of the control group was 7.58 log cfu/g throughout
248 the challenge without significant difference with respect to the pre-administration period (day 0).
249 On the contrary, the excreted faecal *Enterobacteriaceae* of sows subjected to feeding with *L.*
250 *plantarum* 4.1 and *L. reuteri* 3S7 was in the range of 5.33 to 4.88 log cfu/g. The population of
251 *Enterobacteriaceae* increased to 6.0 log cfu/g only after 7 days of post-administration but it was
252 always lower than the number of baseline (7.64 log cfu/g) (Fig. 4). The averaged number of
253 *Enterobacteriaceae* in the piglet faeces of the control group was 6.25 log cfu/g with slight
254 variations (less than 0.5 log cycle) found during the challenge (Fig. 5). The population of
255 *Enterobacteriaceae* detected in the faeces of piglets (5.70 log cfu/g) before administration of
256 lactobacilli linearly decreased to 3.65 log cfu/g at the end of administration (15 days). This cell
257 number of *Enterobacteriaceae* persisted until 3 days of post-administration to further increase only
258 after 6 days.

259

260 3.5 β -glucuronidase

261 The rate of *p*-nitrophenyl- β -D-glucuronide degradation by faecal enzymes during treatment with
262 lactobacilli is shown in Figure 6A and B. β -glucuronidase activity of control pigs was limited in a
263 very narrow range, 27.9 – 30.1 U and 18.7 – 23.3 U for sows and piglets, respectively. During
264 lactobacilli administration a significant ($P < 0.05$) decrease of the enzyme activity was found in all
265 the pigs. Compared to the control group, the β -glucuronidase activity of sows fed with lactobacilli
266 decreased of ca. 28.9% after 7 days and of 36.4 - 43.3% during the remaining 63 days (Fig. 6A). A
267 similar decrease of the faecal enzyme activity (23.0 – 37.4%) was found in piglets fed with
268 lactobacilli (Fig. 6B). After 6 days of post-administration, the β -glucuronidase activity had still a
269 lower value than the baseline.

270

271 4. Discussion

272 Before human or animal application, probiotic bacteria must be thoroughly tested. Overall, pigs
273 are chosen as experimental animals since the comparability of their digestive and circulatory
274 systems to those of humans (Muralidhara et al., 1977; Singer et al., 2003). *L. plantarum* 4.1 and *L.*
275 *reuteri* 3S7 were previously *in vitro* characterized for their bile-salt and low pH resistance (De
276 Angelis et al., 2006). Nevertheless, laboratory testing may only provide useful evidences for
277 selection of potentially effective probiotic strains, but performances in the gut and effects on
278 intestinal microflora need to be accurately determined *in vivo* (Gardiner et al., 2004). The
279 complexity of the intestine may lead to variation among animals and, therefore, probiotic strains
280 may have different effects. From this perspective mixtures of strains are recommended (Gardiner et
281 al., 2004). Due to their survival during the pelleting process (De Angelis et al., 2006), pig faecal
282 isolates of *L. plantarum* 4.1 and *L. reuteri* 4S7 were used for an *in vivo* trial based on the
283 administration of pelleted feed containing selected lactobacilli. Microbiological analyses of faeces
284 from animals fed with a diet without additives revealed usual numbers of lactic acid bacteria in the
285 range 8.8 – 9.11 log cfu/g (Gardiner et al., 2000). In this study, the population of faecal lactobacilli
286 in piglets was ca. 2 log cycles lower than that of adults, but the same species were identified in sows
287 and piglets (*L. reuteri*, *Lactobacillus crispatus*, *L. plantarum*, *Lactobacillus mucosae*, *Lactobacillus*
288 *amylovorus* and *Lactobacillus intestinalis*). As already shown by du Toit et al. (1998), no increases
289 of the faecal *Lactobacillus* cell number was found in sows when fed with lactobacilli. On the
290 contrary, the cell number of lactobacilli significantly ($P<0.05$) increased in piglets feed with
291 lactobacilli (Chang et al., 2001). After 3 or 7 days of administration, all treated pigs excreted 6.0 –
292 7.5 log cfu/g of the ingested strains. The cell number of administrated strains in pig faeces was
293 similar to that found in other studies (Gardiner et al., 2004). After 3 and 6 days of post-
294 administration, the faecal population of lactobacilli in treated piglets was higher than that of the
295 control group. The findings of this study suggested that the increased cell density of *Lactobacillus*
296 in piglets was not only due to the administrated strains but also to the increased cell number of

297 endogenous lactobacilli. A stimulatory effect on the growth/survival of endogenous lactobacilli in
298 the pig intestine has been shown for *Lactobacillus casei* SHIROTA (Ohashi et al., 2001).

299 Pelleting is a process that eliminates problems for pig diets with small particle sizes, decreases
300 dustiness and segregation of ingredients, and increases bulk density. Pelleting diets improved feed
301 efficiency of gain compared to the same diet in meal form. The selected strains used in this study
302 could be used as additives in pelleted diet.

303 *L. plantarum* 4.1, and *L. reuteri* 3S7 were recovered after 6 days of post-administration,
304 indicating that these strains persisted in the GIT of pigs. These results agreed with previous studies
305 showing the persistence of other probiotic *Lactobacillus* strains for 3 to 10 days (Rogelj et al., 2002;
306 Gardiner et al., 2004). To our knowledge, none of the human probiotics actually colonises the
307 intestinal tract but are washed out after a couple of days / a few weeks post-administration.

308 Previously, *L. plantarum* 4.1, and *L. reuteri* 3S7 were *in vitro* characterized for the
309 antimicrobial activity towards *Salmonella enterica* serovar *Typhimurium* and *E. coli* ED36 and
310 ED38 (De Angelis et al., 2006). The two *E. coli* strains produced a verocytotoxin 2e (VT2e) variant
311 causing vascular lesions in the intestine, subcutis and brain, and leading to edema and neurological
312 symptoms (Imberechts et al., 1992; Bertschinger et al. 1999). This study aimed at *in vivo* showing
313 the antimicrobial activity of the selected lactobacilli. Jørgensen et al. (1999) demonstrated a clear
314 positive correlation between the incidence of *Salmonella*-positive pigs and the density of coliform
315 bacteria in the GIT of pigs. The findings of this study showed that selected lactobacilli inhibited in
316 part the faecal *Enterobacteriaceae* microbiota. After 7 – 15 days of lactobacilli administration, the
317 averaged cell number of faecal *Enterobacteriaceae* in sows and piglets was decreased of 2 – 2.6 log
318 cycles. The decrease of the *Enterobacteriaceae* persisted during 6 days of post-administration. Also
319 other studies (Chang et al., 2001; Gardiner et al., 2004) showed decreases of the intestinal coliform
320 and *Enterobacteriaceae* numbers after administration of lactic acid bacteria, even though other
321 authors (De Cupere et al., 1992; Gardiner et al., 1999) did not show the same effect.

322 Haberer et al., (2003) showed that the administration of lactobacilli to pigs caused a marked
323 decrease of the faecal β -glucuronidase activity. Several investigations also showed an influence of
324 the intake of lactobacilli and fermented milk products on the gut flora enzyme activities associated
325 with colon carcinogenesis (Wollowski et al., 2001). Bacterial β -glucuronidase seems to play an
326 important role in initiating colon cancer due to its wide substrate specificity and the hydrolysis of
327 many different glucuronides (Hawksworth et al., 1971; Lidbeck et al., 1992). As a consequence of
328 β -glucuronidase activity, toxic compounds already detoxified in the liver by conjugation are
329 regenerated by the release of toxic aglycones, thus delaying their excretion (Wollowski et al., 2001).
330 Enterobacteria and clostridia show the highest level of bacterial β -glucuronidase activity
331 (Hawksworth et al., 1971). The findings of this study are consistent with those of Goldin and
332 Gorbach (1984) which used an oral supplement of *Lactobacillus acidophilus* to partially replace the
333 human intestinal microbiota and to significantly decrease the level of β -glucuronidase activity. At
334 this purpose pigs provide a suitable model system since their GIT is physiologically and
335 anatomically similar to that of humans (Ayebo et al., 1980).

336 The results of this study showed that *L. plantarum* 4.2 and *L. reuteri* 3S7 have the capacity to: (i)
337 survive in the sows' and piglets' intestine; (ii) stimulate the growth of endogenous *Lactobacillus* in
338 piglets; (iii) inhibit the enterobacteria population in GIT; and (iv) to inhibit β -glucuronidase activity
339 in faecal samples. The use of *L. plantarum* 4.2 and *L. reuteri* 3S7 in pelleted feed for pigs will be
340 further investigated. In particular, pigs with spontaneous diarrhoeal syndrome and pigs infected by
341 certain pathogenic such as *S. enterica* serovar *Typhimurium* or *E. coli* strains will be considered. In
342 future studies, *L. plantarum* 4.2 and *L. reuteri* 3S7 will be also assayed for their possible human
343 applications.

344 **Legends to figures**

345 **Fig. 1.** Faecal excretion of total viable lactobacilli in sows during feed administration with or
346 without the mixture of *L. plantarum* 4.1 and *L. reuteri* 3S7. Each determination was carried out in
347 triplicate. Values are the means of the results of five pigs (fed with culture mix) or two pigs
348 (control) with standard error indicated by vertical bars.

349 **Fig. 2.** Faecal excretion of total viable lactobacilli in piglets during feed administration with or
350 without a mixture of *L. plantarum* 4.1 and *L. reuteri* 3S7. Each determination was carried out in
351 triplicate. Values are the means of the results of two piglets (fed with culture mix) or two piglets
352 (control) with standard error indicated by vertical bars.

353 **Fig. 3.** Randomly amplified polymorphic DNA (RAPD) polymerase chain reaction (PCR) profiles
354 (generated with primer M13) of faecal isolates from sows and piglets fed with lactobacilli. Lanes:
355 S, DNA molecular size standards; lane 1, *Lactobacillus reuteri* 3S7 parental strain; lanes 2-15,
356 chloramphenicol or streptomycin resistant isolates which differed from strains 3S7 and 4.1; lane 16,
357 *Lactobacillus plantarum* 4.1 parental strain.

358 **Fig. 4.** Faecal excretion of total viable *Enterobacteriaceae* in sows during feed administration
359 with or without a mixture of *L. plantarum* 4.1 and *L. reuteri* 3S7. Each determination was carried
360 out in triplicate. Values are the means of the results from five pigs (fed with lactobacilli) or two
361 pigs (control) with standard error indicated by vertical bars.

362 **Fig. 5.** Faecal excretion of total viable *Enterobacteriaceae* in piglets during feed administration
363 with or without a mixture of *L. plantarum* 4.1 and *L. reuteri* 3S7. Each determination was carried
364 out in triplicate. Values are the means of the results from two piglets (fed with culture mix) or two
365 piglets (control) with standard error indicated by vertical bars.

366 **Fig. 6.** Faecal β -glucuronidase activity of piglets (A) and sows (B) during feed administration with
367 or without a mixture of *L. plantarum* 4.1 and *L. reuteri* 3S7. Each determination was carried out in
368 triplicate. Values are the means of the results with standard error indicated by vertical bars.
