1 **Abstract**

2 Current typing methods for *Staphylococcus aureus* have important drawbacks. We
3 evaluated a Multiple Locus Variable-number tandem repeat Analysis (MLVA) scheme
4 with 6 loci which lacks most drawbacks on 85 bovine mastitis isolates from The
5 Netherlands. For each locus the number of repeat units (RU) was calculated. Each
6 combination of repeat units was assigned a MLVA-type (MT). We compared the MLVA
7 typing result with Multi Locus Sequence Typing (MLST), *spa*-typing and Pulsed-Field
8 Gel Electrophoresis (PFGE). MLVA typing resulted in 18 MTs, although 3 loci could not
9 always be amplified. *Spa*-typing distinguished 10 *spa*-types including 3 dominant and 2
10 new types. PFGE showed 5 dominant profiles with 15 related profiles and 6 unique
11 profiles. MLST showed 4 dominant STs. Some types appeared to be bovine specific. The
12 Simpson's Indices of diversity for PFGE, MLST, *spa*-typing and MLVA were 0.887,
13 0.831, 0.69 and 0.781, respectively, indicating that discriminatory power of MLVA was
14 between MLST and *spa*-typing, whereas PFGE displayed the highest discriminatory
15 power. However, MLVA is fast and cheap when compared to the other methods. The
16 Adjusted Rand index and Wallace's coefficient indicated that MLVA was highly
17 predictive for *spa*-type, but not vice versa.

18 Analysis of the region neighboring SIRU05 showed a difference in the genetic element
19 bordering the repeats of SIRU05 that explained the negative SIRU05 PCRs. PFGE,
20 MLST, and MLVA are adequate typing methods for bovine-associated *Staphylococcus*
21 *aureus*

22

23

24

25 1. Introduction

26

27 *Staphylococcus aureus* is a major agent of contagious mastitis in dairy cattle. The sources
28 of bovine mastitis cases mostly are from bovine origin, but *S. aureus* originating from the
29 farmer are another important source (Zadoks et al., 2002). In 2005 it was reported that
30 each year at least 25% of all milking cows in The Netherlands suffer from clinical
31 mastitis which is not only due to *S. aureus* (32%) as a causative agent (Lam, 2005). Many
32 different typing methods have been used. From a “gold standard” Pulsed-Field Gel
33 Electrophoresis (PFGE) to Multi Locus Sequence Typing (MLST) and *S. aureus*-specific
34 staphylococcal Protein A typing known as *spa*-typing (Enright, et al., 2000; Harmsen et
35 al., 2003; Struelens et al., 1992). However, not all methods can be used in all centers
36 because some methods are still limited to well-equipped laboratories. Furthermore, both
37 MLST and *spa*-typing have insufficient discriminatory power to allow accurate
38 delineation of outbreaks and PFGE is a fingerprinting method which makes
39 interlaboratory comparison difficult (van Belkum et al., 1995).

40 A limited number of molecular studies have been published that explored the population
41 structure and genetic relationships of *S. aureus* causing bovine mastitis (de Sousa et al.,
42 2007; Hata et al., 2006; Jørgensen et al., 2005; Katsuda et al, 2005; Reinoso et al., 2008).

43 The results of our recent study demonstrated that a multiple locus variable number of
44 tandem repeats (VNTR) analysis (MLVA) could be used as a fast, inexpensive, highly
45 discriminatory, reproducible, stable and portable typing method for epidemiological
46 tracing of human *S. aureus*. (Ikawaty et al., 2008). Therefore, we aimed to expand the use
47 of this novel MLVA scheme to *S. aureus* isolated from clinical cases of bovine mastitis
48 and to get insight in their genetic relationship with the human *S. aureus* population.

49 **2. Methods**

50

51 *2.1. Strain collection*

52 Eighty five *Staphylococcus aureus* isolates of clinical or subclinical cases of mastitis
53 were included. Thirty five isolates were obtained by the Faculty of Veterinary Medicine
54 Utrecht University, Utrecht, The Netherlands from at least 26 farms near Utrecht. Isolates
55 from farms sampled twice were taken at least one year apart. Another 50 isolates were
56 collected by the Animal Health Service in Deventer, The Netherlands for the Central
57 Veterinary Institute, Lelystad, The Netherlands from farms throughout The Netherlands.
58 The sources were individual teat milk samples from dairy cattle from all over the country
59 from clinical or subclinical cases of mastitis. Each isolate from CVI represents one farm,
60 the location of the farms is unknown but they are distributed all over the Netherlands. All
61 isolates were methicillin-susceptible *Staphylococcus aureus* (MSSA) and collected
62 between 1988 and 2005.

63

64 *2.2. Genomic DNA preparation*

65

66 The isolates were grown on blood agar (Trypticase soy agar II containing 5%
67 sheep blood) overnight at 37°C prior to DNA isolation. Preparation of bacterial genomic
68 DNA was performed using the NucleoSpin kit (Macherey-Nagel) following the protocols
69 from the manufacturer with the exception that bacterial pellet is resuspended in buffer T1.
70 In our method, T1 buffer was replaced by freshly-made lysis buffer that contained 20mM

71 Tris/HCl, 2mM EDTA, 1% Triton X-100, and supplemented with lysostaphin,
72 achromopeptidase and RNase.

73

74 2.3. *MLVA typing*

75

76 A combination of 6 loci (SIRU01, 05, 07, 13, 15 and 21 (*spa*)) from a previous study by
77 Hardy *et. al.* were used for MLVA typing (Hardy et al., 2006). Amplification of SIRUs
78 (Staphylococcal Interspersed Repeat Units) was performed as described before (Ikawaty
79 et al., 2008).

80

81 2.4. *Assignment of MLVA type (MT)*

82

83 The number of repeats for each locus was determined by subtracting the size of the
84 flanking regions from the size of the amplicon followed by division by size of the repeat
85 (Table 1). The repeat number obtained was rounded up or down to the closest integer
86 copy number. A number string resulted from combination of repeat units from SIRU01,
87 05, 07, 13, 15 and 21 was obtained after calculating the number of repeat units of all loci.
88 This was considered an allelic profile and used for the assignment of an MLVA type
89 (MT).

90

91 2.5. *Spa-typing*

92

93 Amplification and sequencing of the repeat region of *S. aureus* Protein A gene (*spa*) was
94 performed by using a specific primer set as described (Harmsen et al., 2003). The
95 amplicon was sequenced using BigDye terminator version 3.1 on ABI 3100 sequencer
96 (Applied Biosystem). BioNumerics (version 3.5; Applied Maths) was used to analyze the
97 obtained sequences and to assign the *spa*-types. Novel *spa*-types were submitted to the
98 Ridom SpaServer database (www.SpaServer.ridom.de).

99

100 2.6. Pulsed Field Gel Electrophoresis

101

102 Bacterial isolates were genotyped by PFGE as described previously (Tenover et al.,
103 1995). Digestion of chromosomal DNA was performed overnight using the restriction
104 enzyme *Sma*I at a temperature 25°C. Fragments were separated on 1% gel. Isolate
105 relatedness was determined using the Tenover criteria (Tenover et al., 1995).

106

107 2.7. MLST analysis

108

109 Determination of the sequence type of 85 *S. aureus* from bovine mastitis were performed
110 as described (Enright, et al., 2000) and data were analyzed using BioNumerics software
111 and the MLST database (www.mlst.net). The outcome of MLST of bovine mastitis *S.*
112 *aureus* was compared with the total population of human *S. aureus* isolates from our
113 database (data not shown) and the MLST.net database.

114

115 2.8. Comparison of MLVA, *spa*-typing, MLST and PFGE

116

117 BioNumerics software was used as a tool for clustering the observed MLVA types (MTs)
118 and MLST types (STs). The discriminatory power of the typing methods was calculated
119 by using EpiCompare version 1.0 (Ridom GmbH, Wurzburg, Germany) as well as for the
120 determination of Adjusted Rand index and Wallace's coefficients.

121

122 2.9. Analysis of SIRU05 locus

123

124 Further analysis of the SIRU05 locus was performed by PCR and sequencing using
125 specific primer sets (lysR- For: 5'-GGA AGC AGA TTT AGG TTA TG-3' and fosB-lys-
126 Rev: 5'-CCA GTC AAT AGC AAT TTT CC-3' for amplification fragment A; lysR-For:
127 5'-TTT GTT CAT CTT GGC TTA GG-3' and ISRX-lys-Rev: 5'-GGA AGT TAC AAT
128 CAT TTG CG-3' for fragment B) based on reference strain of bovine *S. aureus* RF122
129 (Figure 1). DNA sequencing was performed as described for *spa*-typing.

130

131

132 3. Results

133

134 3.1. MLVA

135

136 Among 6 SIRUs used in this typing method, no amplifications were detected for SIRU13,
137 07 and 05 in 47.6%, 91.8% and 100% of the cases, respectively (Table 1). Variations in
138 the number of repeat units ranged from 0 to 12 repeat units (Table 1). Absence of PCR

139 amplification was considered as giving a null allele and is assigned 999 for the repeat
140 number (Table 2). The MLVA typing of 85 isolates produced 18 different allelic profiles
141 or MLVA types . MT102 was most common with 35 isolates, followed by MT112
142 (n=17), and MT118 (n=8).

143

144 3.2. *Spa*-typing

145

146 Ten *spa*-types were obtained from 85 isolates, including 2 new *spa*-types (t2112 and
147 t2248). Seventy three isolates belonged to three dominant *spa*-types, t529 (n=39), t543
148 (n=22) and t524 (n=17) (Table 2). The number of repeats obtained by *spa*-typing for all
149 isolates tested were corresponding with the number of repeats determined by MLVA for
150 SIRU21.

151

152 3.3. Pulsed-Field Gel Electrophoresis

153

154 DNA of 85 isolates was digested with *Sma*I and showed 26 PFGE profiles, 5 groups of
155 closely related PFGE profiles (5 dominant profiles with 15 related to dominant profiles)
156 and 6 unique PFGE profiles (Figure 2).

157

158 3.4. MLST

159

160 Sequencing of the seven housekeeping genes of all isolates identified 4 dominant MLST
161 types (STs), ST 504 (n=24), ST 479 (n=21), ST71 (n=11), ST 151 (n=11), and 11 STs
162 that have not been described previously in the database at <http://saureus.mlst.net> (Table
163 2). A minimum spanning tree of the ST of the 85 isolates compared to the whole
164 population of *S. aureus* showed 3 distinct clusters with bovine mastitis *S. aureus* isolates
165 although some isolates clustered with known human sequence types (Figure 3).

166

167 3.5. Comparison of MLVA, *spa*-typing, PFGE and MLST

168

169 Discriminatory power of the four typing methods, PFGE, MLST, *spa*-typing and MLVA
170 was determined by calculating Simpson's index of diversity with 95% Confidence
171 Interval (CI) of the isolates typed by these methods. PFGE showed higher discriminatory
172 power compared to MLST, *spa*-typing, and MLVA (0.887, 0.831, 0.69 and 0.781,
173 respectively) (Table 3), but the 95% CI of MLVA overlapped with those of *spa*-typing
174 and MLST. It is remarkable that all 3 major *spa*-types contained multiple ST (Table 2).

175

176 3.6. Analysis of the neighboring region of SIRU05

177

178 SIRU05 could not be amplified for any of the isolates. Therefore, the presence of
179 sequences bordering SIRU05 was investigated. In human-derived SIRU05-positive
180 strains SIRU05 is flanked by a LysR regulatory protein family gene at one side and a
181 fosfomycin resistance encoding gene (*fosB*) followed by the *hutG* gene which putatively
182 encodes a formimidoylglutamase. In the sequenced bovine strain RF122 the fosfomycin

183 resistance gene is replaced by insertion sequence *ISRX*. One primer set was used to
184 amplify the *lysR* region (fragment A) and a second set was used to amplify the region
185 between the *lysR* gene and *hutG* (Figure 1). All isolates were positive for amplification of
186 fragment A and B. Sequencing of fragment A and B of 10 isolates showed a single
187 nucleotide mutation in the *lysR* gene resulting a premature stop-codon and the absence of
188 *ISRX*. A new primer designed in the *hutG* gene which was combined with the original
189 primer of SIRU05 in the *lysR* gene did not show differences in the number of repeat units
190 for this locus.

191

192 3.7. The congruence between PFGE, MLST, *spa*-typing and MLVA

193

194 Adjusted Rand's and Wallace's coefficients were calculated to explore the concordance
195 between typing methods (Table 4 and 5). The Adjusted Rand's coefficient for the
196 comparison of the clustering by MLVA and PFGE, MLVA and MLST, and MLVA and
197 *spa*-typing was 0.385, 0.442 and 0.758, respectively. Considering MLVA as the test
198 typing method for comparison, the value of Wallace's coefficients showed that MLVA
199 could only poorly predict the PFGE and MLST type. The probability of two strains
200 having the same MLVA type and sharing the same *spa*-type was 99% (Wallace's
201 coefficient 0.991), whereas the reverse was reasonably predictive (Wallace's coefficient
202 0.699). This finding reflects that MLVA was less discriminatory than MLST and PFGE.

203

204 We observed variation of *spa*-type and MT within the same MLST type as shown by ST
205 97 and 479 isolates, although an identical *spa*-type isolates also showed variation of STs
206 that were closely related (single locus variants or SLVs) to possibly related (3 loci
207 different).

208 Identical t524 isolates had new STs: ST1119, 1125, 1126, 1127, and 1129 that were
209 SLVs and ST1128 that was a double locus variant (DLV) of ST71.

210

211

212 **4. Discussion**

213

214 MLVA has shown great potential for fast and reliable typing of pathogenic bacteria. Our
215 previous study demonstrated that a newly developed MLVA scheme for human *S. aureus*
216 had higher discriminatory power compared to PFGE, MLST and *spa*-typing (Ikawaty et
217 al., 2008). A major advantage of the proposed MLVA scheme is that it requires only
218 simple laboratory equipment and is fast and relatively cheap to perform. This scheme
219 provides better and more timely access to typing of bovine mastitis. This allows more
220 adequate surveillance of mastitis and the identification of particular virulent or epidemic
221 strains. Early recognition of these strains may help to initiate more timely therapy and
222 other interventions to prevent further spread. In this study, we extended the use of the
223 MLVA typing scheme for human *S. aureus* to bovine *S. aureus* from clinical mastitis.
224 Eighty five isolates represented regional (n=35) and national (n=50) *S. aureus* isolates.
225 The isolates were not considered to belong to local outbreaks as 90% of the isolates were
226 obtained on different farms whereas the remaining isolates were obtained at least one

227 year apart when sampled on the same farm. The scheme showed good typeability
228 although 3 loci (SIRU05, 7 and 13) were not always amplified. SIRU21 had the most
229 variance in the number of repeat units, which is important in typing by MLVA.
230 We observed no particular difference between regionally and nationally obtained *S.*
231 *aureus* bovine mastitis strains in terms of PFGE profile, MLST and *spa*-types, except for
232 one MLVA type (MT 118) that was only present among regionally obtained isolates, but
233 due to the limited number of isolates further analysis using more samples is needed.
234 The number of repeat units obtained by amplification of SIRU21, having the smallest
235 repeat unit, agreed completely with the number of repeats obtained by DNA sequencing
236 for *spa*-typing indicating the reliability of the determination of the number of repeat units.
237 SIRU05 was analyzed more in depth, since it could not be amplified in any of the bovine
238 isolates including 4 isolates with ST97 that were already known as possibly human
239 derived (Smith et al., 2005a; Sung et al., 2008). PCR of the region neighboring SIRU05
240 demonstrated that all isolates were fragment A and B positive. Sequencing of the
241 fragments of 10 isolates showed that *ISRX* and the fosfomycin resistance element were
242 lacking. The difference in the genetic element bordering the repeats of SIRU05 explains
243 the negative result of SIRU05 PCR, since the primer chosen in the fosfomycin resistance
244 element could not anneal to the *ISRX* element or the *hutG* gene. Amplification of SIRU05
245 with a primer chosen in *hutG* showed no variation in the number of repeat units. SIRU05
246 does not contribute to the discrimination of the isolates tested and can be omitted from
247 the scheme for bovine mastitis isolates. It should be noted that the primer sets used in this
248 MLVA scheme were developed based on human *S. aureus*.

249 LysR is a member of the largest family of bacterial activator/regulator proteins (Henikoff
250 et al.,1988; Zaim and Kierzek. 2003). The LysR protein contains a substrate recognition
251 site and a helix-turn-helix DNA-binding motif crucial for protein-DNA interaction (Zaim
252 and Kierzek. 2003). In bovine *S. aureus* a stop-codon is present, which prevents
253 transcription of the substrate domain. This should inactivate LysR leading to different
254 expression patterns in bovine strains compared to human strains.

255

256 A minimum spanning tree based on MLST showed that clustering of bovine *S. aureus*
257 was different than for isolates from the human population. The difference between human
258 and bovine derived isolates has been suggested to be caused by tissue specificity by some
259 authors (Gilbert et al., 2006; Smith et al., 2005a) while most authors assumed host
260 specificity among *S. aureus* clones (de Sousa et al., 2007; Kapur et al.,1995). Two of the
261 three dominant MLST types (ST151 and 504) were clustered together while ST479 was
262 distantly related to ST151 and ST504. They were not related to human-derived *S. aureus*.
263 Eleven isolates from both regional and national origin were ST71 which is known to be a
264 bovine-associated strain from The Netherlands (Smith et al., 2005a). Interestingly, the 11
265 new STs isolates fell into a cluster which was not related to the known bovine STs. Little
266 sharing of strains between the bovine and human population has been reported (Kapur et
267 al.,1995). A similar finding was made by Rabello et al for Brazilian isolates (Rabello et
268 al., 2007).

269

270 The ST or clonal complexes (CC) of bovine mastitis isolates from The Netherlands
271 differed from those described elsewhere with the exception of 4 isolates (S0337, S0426,

272 S0431 and S0436) that belonged to CC97. CC97 isolates have previously been reported
273 to be obtained from humans (Feil et al., 2003). In Brazil CC97 and CC127 were
274 predominant (Rabello et al., 2007). CC97 was also present in isolates from the UK, the
275 USA and Chile (Smith et al., 2005a; Smith et al., 2005b). A different set of STs was
276 obtained from milk in Norway where ST130 (CC3), ST133 and ST132 (CC1) were
277 predominant (Jørgensen et al., 2005).

278

279 The highest discriminatory power was obtained by PFGE followed by MLST, MLVA
280 and *spa*-typing. Because SIRU05 yielded no usable data a lower discriminatory power of
281 MLVA compared to the *spa*-typing was expected. But the results demonstrated that
282 MLVA had a higher Simpson's index of diversity than *spa*-typing.

283 We observed variations in related STs within the same *spa*-type as shown in Table 2. The
284 limited number of *spa*-types might suggest selective pressure on the *spa* gene and it may
285 explain their maintenance in the population of bovine-derived *S. aureus*. This finding
286 suggests that *spa*-typing is not a useful method to compare bovine mastitis isolates.

287 Transfer of antibiotic resistance from human to animal isolates or the other way around
288 has been a major concern (Pesavento et al., 2007; Zadoks et al., 2002). Host specificity of
289 clones may reduce the chance that human-derived antibiotic-resistant *S. aureus* isolates
290 are transmitted to cattle, although bovine mastitis may occasionally be caused by human-
291 derived isolates. Typing of *S. aureus* from bovine mastitis will be required to monitor
292 potentially changing population dynamics. Based on our data PFGE, MLST, and MLVA
293 are adequate typing methods for international studies and local studies of bovine *S.*

294 *aureus* isolates involved in mastitis. However, PFGE and MLST are more time-
295 consuming and/or expensive than MLVA.

Table 1. Size of the MLVA loci, formula for calculating the number of repeat units (RU) per locus, typeability of MLVA and variation in repeat units observed.

Locus (size in bp)	Formula	Number (%) PCR negative	No. of repeats (RU)[*]
SIRU01 (55)	$(n-157-30)/55$	0 (0.0)	1 – 6
SIRU05 (60)	$(n-76-78)/60$	85 (100)	-
SIRU07 (56)	$(n-27-160)/56$	78 (91.8)	2 – 3
SIRU13 (64)	$(n-76-78)/64$	49 (47.6)	1 – 5
SIRU15 (131)	$(n-48-174)/131$	0 (0.0)	0 – 3
SIRU21 (24)	$(n-12-81)-16)/24$	0 (0.0)	2 – 12

n: Size of fragment in bp

* : values are in repeat unit (RU)

Table 2. Comparison of PFGE, MLST, *spa*-typing and MLVA results.

No.	Isolate	Date of isolation	Source	PFGE profile	MLST type	<i>Spa</i> - type	MLVA type	SIRU ^a

Legend

Figure 1. Strategy for analyzing the region bordering the SIRU5 locus. The bovine *S. aureus* (BSA) RF122 reference strain showed a different genetic structure compared to human *S. aureus* reference strains. The genetic element at the right of the repeat region consists of a fosfomycin resistance gene in human *S. aureus* and was replaced by insertion site region X (ISR_X) in RF122. A single nucleotide mutation in *lysR* gene region was present in RF122. The primers were designed to detect the presence/absence of a single nucleotide mutation (fragment A) by DNA sequencing and the presence of fosfomycin resistance gene or ISR_X structure (fragment B).

Figure 2. Dendrogram containing PFGE patterns of 85 MSSA strains collected from bovine. At the 50% similarity level, seven branches are distinguished. ID: isolate ID; ST: MLST type.

Figure 3. Minimum spanning tree of *S. aureus* based on MLST. Five major clonal complexes are present within the *S. aureus* population: CC5, CC8, CC22, CC30 and CC45. Each circle represents a different MLST type. Single locus variant STs are connected by a thick line, double locus variant STs by a thin line, triple locus variant STs by a dark grey dashed line, and STs with more than 3 loci variant are connected by a light grey dashed line. Red circles indicate *S. aureus* isolated from bovine mastitis. Arrows indicated new MLST types observed in this study: 1: ST 1118; 2: ST 1119; 3: ST 1121; 4: ST 1122; 5: ST 1123; 6: ST 1124; 7: ST 1125; 8: ST 1126; 9: ST 1127; 10: ST 1128; 11: ST 1129.
