**Summary.** The existence of the shortest confidence interval for binomial probability is shown. The method of obtaining such an interval is presented as well.

**Key words:** binomial proportion, confidence interval, shortest confidence intervals

AMS 2000 Subject Classification: 62F25

Consider the binomial statistical model

$$(\{0, 1, \dots, n\}, \{Bin(n, \pi), 0 < \pi < 1\}),$$

where  $\text{Bin}(n, \pi)$  denotes the binomial distribution with pdf

$$\binom{n}{x} \pi^x (1 - \pi)^{n-x}, \quad x = 0, 1, \dots, n.$$

Let  $X$  denote a binomial  $\text{Bin}(n, \pi)$  random variable. A confidence interval for the probability  $\pi$  at the confidence level  $\gamma$  is of the form (Clopper and Pearson, 1934)

$$\left( F^{-1}(X, n - X + 1; \gamma_1); F^{-1}(X + 1, n - X; \gamma_2) \right),$$

where  $\gamma_1, \gamma_2 \in (0, 1)$  are such that  $\gamma_2 - \gamma_1 = \gamma$  and  $F^{-1}(a, b; \alpha)$  is the  $\alpha$  quantile of the beta distribution with parameters  $(a, b)$ , i.e.

$$P_\pi \left\{ \pi \in \left( F^{-1}(X, n - X + 1; \gamma_1); F^{-1}(X + 1, n - X; \gamma_2) \right) \right\} \geq \gamma, \quad \forall \pi \in (0, 1).$$

For  $X = 0$  the left end is taken to be 0, and for  $X = n$  the right end is taken to be 1.

Clopper and Pearson (1934) in their construction used  $\gamma_1 = (1 - \gamma)/2$  (see also Brown et al. (2001)), i.e. they applied the rule of symmetric division of  $1 - \gamma$  to both sides of the interval. The length of the confidence interval was not considered as a criterion. It is of interest to find the shortest confidence interval. So we want to find  $\gamma_1$  and  $\gamma_2$  such that the confidence interval is the shortest possible.

The problem of shortest confidence intervals was seldom considered in the past (Crow 1956, Blyth and Hutchinson 1960, Blyth and Still 1983, Casella 1986). Unfortunately, the solutions proposed are either complicated or randomization is applied. In what follows, a much simpler solution of the problem is presented.

Consider the length of the confidence interval when  $X = x$  is observed,

$$d(\gamma_1, x) = F^{-1}(x+1, n-x; \gamma + \gamma_1) - F^{-1}(x, n-x+1; \gamma_1).$$

Let  $x$  be given. We want to find  $0 < \gamma_1 < 1 - \gamma$  such that  $d(\gamma_1, x)$  is minimal. The derivative of  $d(\gamma_1, x)$  with respect to  $\gamma_1$  equals (in what follows  $B(\cdot, \cdot)$  denotes the beta function)

$$\begin{aligned} \frac{\partial d(\gamma_1, x)}{\partial \gamma_1} &= B(x+1, n-x)(1-F^{-1}(x+1, n-x; \gamma + \gamma_1))^{1+x-n} F^{-1}(x+1, n-x; \gamma + \gamma_1)^{-x} \\ &\quad - B(x, n-x+1)(1-F^{-1}(x, n-x+1; \gamma_1))^{x-n} F^{-1}(x, n-x+1; \gamma_1)^{1-x}. \end{aligned}$$

1  
2  
3 Let

$$LHS(\gamma_1, x) = \frac{[1 - F^{-1}(x + 1, n - x; \gamma + \gamma_1)]^{n-x-1} F^{-1}(x + 1, n - x; \gamma + \gamma_1)^x}{B(x + 1, n - x)},$$

$$RHS(\gamma_1, x) = \frac{[1 - F^{-1}(x, n - x + 1; \gamma_1)]^{n-x} F^{-1}(x, n - x + 1; \gamma_1)^{x-1}}{B(x, n - x + 1)}.$$

4 Then  
5  
6  
7  
8  
9

$$\frac{\partial d(\gamma_1, x)}{\partial \gamma_1} = \frac{1}{LHS(\gamma_1, x)} - \frac{1}{RHS(\gamma_1, x)}.$$

10 Because  
11  
12  
13  
14

$$F^{-1}(x, n - x + 1; 0) = 0 \quad \text{and} \quad F^{-1}(x + 1, n - x; 1) = 1,$$

15 for  $1 < x < n - 1$  we have  
16  
17  
18  
19

$$\begin{aligned} \text{if } \gamma_1 \rightarrow 0 \text{ then } LHS(\gamma_1, x) &> 0 \text{ and } RHS(\gamma_1, x) \rightarrow 0^+, \\ \text{if } \gamma_1 \rightarrow 1 - \gamma \text{ then } LHS(\gamma_1, x) &\rightarrow 0^+ \text{ and } RHS(\gamma_1, x) > 0. \end{aligned}$$

20 Therefore, the equation  
21  
22

$$\frac{\partial d(\gamma_1, x)}{\partial \gamma_1} = 0 \tag{*}$$

23 has a solution.  
24

25 It is easy to see that  $LHS(\cdot, x)$  and  $RHS(\cdot, x)$  are unimodal and concave on the interval  $(0, 1 - \gamma)$ . Hence,  
26 the solution of (\*) is unique. Let  $\gamma_1^*$  denote the solution. Because  $\frac{\partial d(\gamma_1, x)}{\partial \gamma_1} < 0$  for  $\gamma_1 < \gamma_1^*$  and  $\frac{\partial d(\gamma_1, x)}{\partial \gamma_1} > 0$   
27 for  $\gamma_1 > \gamma_1^*$ , we have  $d(\gamma_1^*, x) = \inf\{d(\gamma_1, x) : 0 < \gamma_1 < 1 - \gamma\}$ .

28 It is interesting to note that for even  $n$  and  $x = n/2$  the only solution of (\*) is  $\gamma_1^* = (1 - \gamma)/2$ , i.e. the  
29 symmetric confidence interval is the shortest one. Indeed, in that case  
30

$$LHS(\gamma_1, x) = \frac{[1 - F^{-1}(x + 1, x; \gamma + \gamma_1)]^{n-x-1} F^{-1}(x + 1, x; \gamma + \gamma_1)^x}{B(x + 1, x)},$$

$$RHS(\gamma_1, x) = \frac{[1 - F^{-1}(x, x + 1; \gamma_1)]^{n-x} F^{-1}(x, x + 1; \gamma_1)^{x-1}}{B(x, x + 1)}.$$

31 Making use of the known equality  
32  
33  
34  
35

$$F^{-1}(a, b; q) = 1 - F^{-1}(b, a; 1 - q),$$

36 we can rewrite equation (\*) in the form  
37  
38  
39

$$\left[ \frac{F^{-1}(x, x + 1; \gamma_1)}{F^{-1}(x, x + 1; 1 - \gamma - \gamma_1)} \right]^{x-1} = \left[ \frac{F^{-1}(x + 1, x; \gamma + \gamma_1)}{F^{-1}(x + 1, x; 1 - \gamma_1)} \right]^x.$$

40 It is not difficult to check that the solution of the last equation is  $\gamma_1^* = (1 - \gamma)/2$ .  
41

42 For  $x = 1$  we have  
43  
44

$$LHS(\gamma_1, 1) = \frac{[1 - F^{-1}(2, n - 1; \gamma + \gamma_1)]^{n-2} F^{-1}(2, n - 1; \gamma + \gamma_1)}{B(2, n - 1)},$$

$$RHS(\gamma_1, 1) = \frac{[1 - F^{-1}(1, n; \gamma_1)]^{n-1}}{B(1, n)} = n(1 - \gamma_1)^{\frac{n-1}{n}}.$$

45 It is seen that  
46  
47

$$\begin{aligned} \text{if } \gamma_1 \rightarrow 0 \text{ then } LHS(\gamma_1, 1) &\rightarrow \frac{[1 - F^{-1}(2, n - 1; \gamma)]^{n-2} F^{-1}(2, n - 1; \gamma)}{B(2, n - 1)} \text{ and } RHS(\gamma_1, x) \rightarrow n, \\ \text{if } \gamma_1 \rightarrow 1 - \gamma \text{ then } LHS(\gamma_1, x) &\rightarrow 0 \text{ and } RHS(\gamma_1, x) \rightarrow n\gamma^{\frac{n-1}{n}}. \end{aligned}$$

1  
2  
3 and  
4

$$5 \quad RHS(\gamma_1, 1) > LHS(\gamma_1, 1) \quad \text{for } 0 < \gamma_1 < 1 - \gamma.$$

6 So  $\frac{\partial d(\gamma_1, 1)}{\partial \gamma_1} > 0$  and hence  $d(\gamma_1, 1)$  achieves its minimal value for  $\gamma_1 = 0$ . For  $x = 1$  the shortest confidence  
7 interval is the one-sided one. Similarly, for  $x = n - 1$  the length  $d(\gamma_1, n - 1)$  achieves its minimal value for  
8  $\gamma_1 = 1 - \gamma$  and the shortest confidence interval is also one-sided.  
9

10 The value of  $\gamma_1^*$  for given  $\gamma$ ,  $n$  and  $x$  may be found numerically. Tables 1-3 give those values for  $\gamma = 0.95$ .  
11 Clopper-Pearson confidence intervals are also shown.  
12

13 Note that if  $x > n/2$ , then

$$14 \quad \begin{aligned} \gamma_1^*(x) &= (1 - \gamma) - \gamma_1^*(n - x), \\ 15 \quad left_{short}(x) &= 1 - right_{short}(n - x), \\ 16 \quad right_{short}(x) &= 1 - left_{short}(n - x), \\ 17 \quad left_{sym}(x) &= 1 - right_{sym}(n - x), \\ 18 \quad right_{sym}(x) &= 1 - left_{sym}(n - x). \\ 19 \\ 20 \\ 21 \\ 22 \\ 23 \end{aligned}$$

Below we give a short Mathematica program for calculating  $\gamma_1^*$  and the ends of the shortest confidence interval. Of course, one can also use other mathematical or statistical packages (in a similar way) to find the values of  $\gamma_1^*$ .

In Clopper and Pearson's times calculating quantiles of a beta distribution was numerically complicated. Nowadays, it is very easy with the aid of computer software, so using the shortest confidence interval is recommended, especially for small sample sizes  $n$ .
