2-Adic clustering of the PAM matrix

A.Yu.Khrennikov, S.V.Kozyrev

August 10, 2009

Abstract

In this paper we demonstrate that the use of the system of 2-adic numbers provides a new insight to some problems of genetics, in particular, degeneracy of the genetic code and the structure of the PAM matrix in bioinformatics. The 2-adic distance is an ultrametric and applications of ultrametric in bioinformatics are not surprising. However, by using the 2-adic numbers we match ultrametric with a number theoretic structure. In this way we find new applications of an ultrametric which differ from known up to now in bioinformatics.

We obtain the following results. We show that the PAM matrix \( A \) allows the expansion into the sum of the two matrices \( A = A^{(2)} + A^{(\infty)} \), where the matrix \( A^{(2)} \) is 2-adically regular (i.e. matrix elements of this matrix are close to locally constant with respect to the discussed earlier by the authors 2-adic parametrization of the genetic code), and the matrix \( A^{(\infty)} \) is sparse. We discuss the structure of the matrix \( A^{(\infty)} \) in relation to the side chain properties of the corresponding amino acids.

We introduce the family of substitution matrices \( A(\alpha, \beta) = \alpha A^{(2)} + \beta A^{(\infty)} \), \( \alpha, \beta \geq 0 \) which should allow to vary the alignment procedure in order to take into account the different chemical and geometric properties of the amino acids.

1 Introduction

In spite of considerable efforts during the last 40 years, the problem of degeneracy of the genetic code is still a great mystery [1, 2]. The considerable progress in the study of this problem is related to application of symmetry arguments, [3, 4, 5, 6]. This approach was stimulated by wide and extremely successful use of the group-theoretic methods in physics (both classical and quantum). We claim that this approach, although extremely successful in physics, has quite restricted domain of application for living systems. In the latter case laws of symmetry are satisfied only approximately and they vary strongly with minor variation of living structures (e.g. transition from one type of genetic code to another).

We propose a novel approach based on some (not straightforward) generalization of symmetry arguments. Instead of clustering based on groups of symmetries, we consider clustering based on ultrametricity. The clusters are defined as domains of local constancy of some map (in particular of a function) of an ultrametric argument.

This novel ideology which we hope may find wide application in biology was applied to the problem of degeneracy of the genetic code [7]. We introduce an ultrametric space which provides an adequate representation for the genetic code. It is the so called 2-adic plane (the \( 8 \times 8 \) table of codons with the 2-dimensional 2-adic ultrametric). This representation induces clustering of codons in amino acids which in turn induces clustering of amino acids with similar chemical and physical properties (in particular, hydrophobicity). Clusters are given by ultrametric balls of corresponding radii. Amino acids with strong and weak degeneration of representation by codons form the two clusters on the 2-adic plane, cf. with Rummer’s clustering based on symmetry argument [3, 4]. This observation shows that the applied 2-adic parametrization of the code is related to connection between the genetic code and physico-chemical properties of the amino acids, discussed in [8, 9, 10, 11].

We remark that the use of ultrametric is not surprising in bioinformatics, see e.g. [12, 13, 14, 15] for review. The main novelty of our approach is the use of locally constant clustering functions and consideration of this approach as a generalization of the group-theoretic approach. Moreover, in the problem of genetic code we found...
A really natural ultrametric which is based on 2-adic structure of the genetic alphabet: four letters (nucleotides) A, C, G, T can be naturally represented in the 2-adic base. Thus our model of "genetic space" is based on the combination of 2-adic arithmetics and an ultrametric corresponding to this arithmetics, i.e., the 2-adic metric. Thus there is an interesting relation between "genetic arithmetics" and "genetic geometry" which is explored in the present paper.

Various metrics on the space information strings was considered in [16]. Ultrametric analysis was recently used in theoretical physics (from string theory to theory of disordered systems, spin glasses), see e.g. [17], [18], [19], [20] in cognitive science, psychology and image analysis [21]. The important example of an ultrametric is the p-adic metric (in fact, a class of metrics depending on the parameter p — a prime number). The main distinguishing feature of this metric is its sensitivity to hierarchic patterns in information having a special structure matching with p-adic encoding of information.

A few years ago 2-adic metric was applied to study the problem of degeneration of the genetic code, see [7, 22, 23]. It was shown that, after some special parametrization of the space of codons (triples of nucleotides) the genetic code becomes a locally constant map of 2-adic argument. Moreover, the degeneracy of the genetic code in this language takes the form of local constancy of the corresponding mapping. These 2-adic models can be considered as new development in the approach to investigation of the structure of the genetic code from the point of view of coding theory, see [24, 25].

Let us also mention the application of the p-adic parametrization to the description of the Parisi matrix from the replica symmetry breaking approach to spin glasses [26, 27]. After the p-adic parametrization of the numbers of the lines and the columns the Parisi matrix becomes a locally constant block matrix.

In the present paper we discuss the structure of the PAM matrix used in bioinformatics for sequence alignment (see for example [12]) from the point of view of 2-adic parametrization. The PAM matrix is constructed using a Markov chain model of point mutations for a protein chain.

We assume that the structure of the PAM matrix has some relation to the structure of the genetic code. Using this idea we enumerate the lines and the columns of the PAM matrix using the 2-adic parametrization of the genetic code. After this parametrization the PAM matrix becomes more regular, namely, the dependence of the matrix elements $A_{ij}$ of the PAM matrix on the indices $i$ and $j$ is close to locally constant with respect to the 2-adic norm for the majority of matrix elements.

We have some exceptions from this rule. These exceptions are related to several amino acids, namely to Y, W, C, F, L. In order to describe this deviations from 2-adicity we introduce the following construction: we expand (by hands) the PAM matrix into the sum of the two matrices

$$
A = A^{(2)} + A^{(\infty)}.
$$

The matrix in this expansion $A^{(2)}$ is 2-adically regular (close to locally constant). The matrix $A^{(\infty)}$ is sparse (the majority of matrix elements are zero, non zero matrix elements are mainly concentrated of the lines and columns related to the amino acids Y, W, C, F, L).

One can see that the deviations from 2-adicity (i.e. non-zero matrix elements of $A^{(\infty)}$) are related to amino acids which are in some sense special — to the aromatic amino acids Y, W, F, and to Cysteine C which contains the SH group.

We also mention that the 2-adic structure of the genetic code is related to some chemical properties of the amino acids. In particular, hydrophobic amino acids are clustered in two ball with respect to the 2-adic norm. Therefore the 2-adic parametrization allows to separate the impact of the chemical (described by the matrix $A^{(2)}$) and geometrical (described by the matrix $A^{(\infty)}$) properties of amino acids for the structure of the PAM matrix.

Using this observation we introduce the family of substitution matrices

$$
A(\alpha, \beta) = \alpha A^{(2)} + \beta A^{(\infty)},
$$

The family of matrices $A(\alpha, \beta)$ could be used in the deformed alignment procedure. This procedure, depending on the parameters $\alpha$ and $\beta$, can take into account the different chemical and geometric properties of the amino acids.

---

1 A similar approach was used in cognitive science and psychology [21].
2 2-adic arithmetic operations are continuous with respect to this metric.
3 We remark that to appeal to hierarchical structures is quite common in genetics and bioinformatics in general, see, e.g. [14], [15]. Our main contribution is combining the hierarchic structure approach with number theory.
The structure of the present paper is the following.
In Section 2 we review some known approaches to the genetic code.
In Section 3 we discuss some family of ultrametric spaces.
In Section 4 we describe the 2-adic 2-dimensional parametrization of the genetic code of [7].
In Section 5 we put the PAM250 matrix.
In Section 6 we describe the reordering of the lines and the columns of the PAM matrix, corresponding to
the 2-adic parametrization of the genetic code of Section 2.
In Section 7 we introduce the expansion of the PAM matrix into the sum of the two matrices, one of which
is 2-adically regular (close to locally constant) and the other is sparse (majority of matrix elements are equal
to zero).
Sections 8 and 9 are appendices where the definitions of PAM matrices and the eucaryotic genetic code are
exposed.

2 Approaches to the investigation of the genetic code

Properties of the genetic code were discussed in a number of papers. Here we mention only a few of the discussed
models:
1) the coding theory approach;
2) the symmetry (group theory) approach;
3) the investigation of chemical (stereochemical and physicochemical) properties of the genetic code;
4) biological arguments (coevolution theory).

The original idea by Gamow [1] of the triplet code combined the coding theory ideas and the stereochemical
constraints for the genetic code.

In paper [2] the symmetry of the genetic code was discussed. In particular, it was pointed out that the
genetic code (with the exception for the two codons) is symmetric under the following substitutions at the third
base position: $A \leftrightarrow G$ and $U \leftrightarrow C$.

The important symmetry of the genetic code was observed in [3, 4]. It was found that the set of codons
can be divided in the two subsets: depending on the nucleotides at the first and the second base position, the
genetic code can be either strongly degenerate with respect to the nucleotide at the third base position, or can
be weakly degenerate. The degeneracy is described by the following table with the lines enumerated by the first
nucleotide and the columns enumerated by the second nucleotide.

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>G</th>
<th>U</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P</td>
<td>R</td>
<td>L</td>
<td>*</td>
</tr>
<tr>
<td>G</td>
<td>A</td>
<td>G</td>
<td>V</td>
<td>*</td>
</tr>
<tr>
<td>U</td>
<td>S</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
<tr>
<td>A</td>
<td>T</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

In this table we have put only the amino acids corresponding to the strongly degenerate codons. The Rumer
symmetry is the central symmetry of this table which interchanges the strongly and weakly degenerate codons.

The group of symmetries of the genetic code was discussed in [5].

The full group of symmetries which reproduce the Rumer symmetry was discussed in [28].

Application of quantum group symmetries to genetic code was discussed in [6].

In [24] the genetic code was considered as an example of an error correcting code. It was found that for
a major part of cases point mutations (especially at the third base pair) either leave the corresponding amino
cacid invariant or map it to similar amino acid.

In [25] then degeneracy of the genetic code was investigated from the point of view of some metric on the
space of codons.

Application of the graph theory to description of the hierarchical structure of the genetic code was considered
in [9].

Physical-chemical properties of the genetic code were considered in different works. In [29] interaction of
amino acids with nucleic acids was investigated.

Relation between the properties of amino acids (hydrophobicity, residue volume etc.) and the properties of
the corresponding anticodons was considered in [30].

3
In [8] the grouping of amino acids in relation to the nucleotide at the second position in the codon was discussed.

The relation between symmetries of the genetic code and the properties of the codon–anticodon interaction was considered in [11, 10].

For the review of some approaches to investigation of the genetic code see [31]. In particular, see [31] for the discussion of the coevolution theory (the codon system structure is an imprinting of the prebiotic pathways that formed amino acids).

3 Ultrametric spaces

An ultrametric space is a metric space where the metric \( d(x, y) \) satisfies the strong triangle inequality:

\[
    d(x, y) \leq \max(d(x, z), d(y, z)), \quad \forall x, y, z.
\]

The strong triangle inequality can be stated geometrically: each side of a triangle is at most as long as the longest one of the two other sides. Such a triangle is quite restricted when considered in the ordinary Euclidean space — it is isosceles, i.e., \( d(x, y) = d(y, z) \) or \( d(x, z) = d(y, z) \) or \( d(x, y) = d(z, x) \).

An ultrametric space is a natural mathematical object for description of a hierarchical system. On ultrametric spaces there exist many locally constant functions, i.e., functions which are constant on some vicinity of any point, but not necessarily constant on the whole space. In particular, we show that the genetic code can be considered as a locally constant map on a specially designed ultrametric space, so called 2-adic plane, see [7].

Let \((X, d)\) be an ultrametric space. We consider balls

\[
    U_r(a) = \{ x \in X : d(x, a) \leq r \},
\]

for \( r > 0 \), \( x \in X \). So, \( a \) is the center of the ball \( U_r(a) \) having radius \( r \). We mention a few unusual (from the viewpoint of usual Euclidean geometry) properties of ultrametric balls:

a). Each point of \( U_r(a) \) can be chosen as its center. So, inside a ball all points have “equal rights”.

b). Any two balls either do not intersect or one of the balls contains the other ball. In this framework, clustering into disjoint balls is a very natural operation.

We remark that ultrametric spaces were widely used in bioinformatics, see [12, 13]. However, in this paper we plan to elaborate new applications of ultrametric spaces to biology (genetics) which are different from mentioned ones.

We are interested in the following special class of ultrametric spaces \((X, d)\). Every point \( x \) is the infinite sequence of digits

\[
    x = (\alpha_0, \alpha_1, \ldots, \alpha_n, \ldots).
\]

Each digit yields the finite number of values,

\[
    \alpha_i \in A_m = \{0, \ldots, m-1\},
\]

where \( m > 1 \) is a natural number, the base of the alphabet \( A_m \).

If the sequence \( x = (\alpha_0, \alpha_1, \ldots, \alpha_n, \ldots) \) contains only finite number of non-zero terms \( (\alpha_0, \alpha_1, \ldots, \alpha_n) \), then we can consider \( x \) as the natural number

\[
    x = \sum_{i=0}^{n} \alpha_i m^i.
\]

Moreover, this formula defines the one to one correspondence between natural numbers (with zero) and the space of final sequences \( x = (\alpha_0, \alpha_1, \ldots, \alpha_n) \).

We denote the space of sequences (1), (2) by the symbol \( \mathbb{Z}_m \). Ultrametric is introduced on this set in the following way. For two points

\[
    x = (\alpha_0, \alpha_1, \alpha_2, \ldots, \alpha_n, \ldots), \quad y = (\beta_0, \beta_1, \beta_2, \ldots, \beta_n, \ldots),
\]

we set

\[
    d_m(x, y) = \frac{1}{m^k} \text{ if } \alpha_j = \beta_j, j = 0, 1, \ldots, k - 1, \text{ and } \alpha_k \neq \beta_k.
\]

The ultrametric space \((X = \mathbb{Z}_m, d = d_m)\) is called the space of \( m \)-adic integers.
The ultrametric $d_m$ describes the following hierarchical structure. If $x = (\alpha_1, \alpha_2, \ldots, \alpha_n, \ldots)$, $\alpha_j = 0, 1, \ldots, m-1$, is a vector encoding information on some object, then digits $\alpha_j$ have different weights. The digit $\alpha_0$ is the most important, $\alpha_1$ dominates over $\alpha_2, \ldots, \alpha_n, \ldots$, and so on. Such hierarchical information vectors can be created by living systems, e.g., by the brain to process information. Applications of $m$-adic numbers to information theory and, in particular, to description of cognitive processes and complex social systems were developed in [18, 21, 32, 33, 34, 35, 36].

In applications we will use not only "one dimensional" $m$-adic spaces, but also cartesian products of a few spaces, e.g., $m$-adic plane $Z_m^2 = Z_m \times Z_m$ and so on. Our aim is to show that 2-adic plane structure was embedded in the genetic code, see [7].

We remark that $m$-adic numbers for $m = p$, where $p$ is a prime number were intensively used (during last 20 years) in mathematical physics [17, 20]. The number theoretic definition is as follows.

Let us fix a prime number $p > 1$. For example, fix $p = 2$ or fix $p = 1999$. The example of ultrametric space is the field of $p$-adic numbers $\mathbb{Q}_p$, which is the completion of the field of rational numbers with respect to $p$-adic norm $|x|_p$, defined as follows: for a rational number $x = p^n m/n$, where $\gamma = 0, \pm 1, \pm 2, \ldots$, and $m, n$ are non-zero and are not divisible by $p$, its $p$-adic norm is $|x|_p = p^{-\gamma}$.

$p$-Adic norm is widely used in number theory and algebraic geometry.

If a rational number is divisible by $p^n$, where $\gamma$ is very large, then its $p$-adic norm is very small. This hierarchy of the degrees of $p$ (i.e. of values of the $p$-adic norm) gives the hierarchical (ultrametric) structure of the $p$-adic norm. $p$-Adic numbers are in one to one correspondence with the series

$$x = \sum_{i=\gamma}^{\infty} x_i p^i,$$

where $\gamma$ is integer and $x_i \neq 0$ (this expansion is the analogue of (3)).

The unit ball in $\mathbb{Q}_p$ with center at $a = 0$ zero coincides with the space of $p$-adic integers $\mathbb{Z}_p$.

$p$-Adic numbers were actively used (since pioneer papers of I.Volovich, [37]) in high energy physics (superstring theory, cosmology) and theory of disordered systems (spin glasses), see, e.g., review [20] and the book [17].

The mentioned in the present section properties of balls in an ultrametric space imply that on ultrametric spaces there are a lot of locally constant functions. For a locally constant function on $(X, d)$ any point $x \in X$ has a vicinity $B$ (a ball) on which the function is constant:

$$f(x) = f(x'), \quad x, x' \in B.$$

Taking the infimum $R$ of the diameters of these vicinities (over all points in $X$), we obtain that the locally constant function is invariant with respect to translations

$$x \mapsto x + r, \quad \text{if} \quad d(r) \leq R.$$

Here we assume that the ultrametric space $X$ under consideration is an additive group, say, one of the groups considered in the present section.

Therefore a local constancy property can be considered as a particular case of translation symmetry. On the other hand, points in the different subsets of $X$ might possess the different diameters of local constancy. From this point of view for an ultrametric space the local constancy property is a generalization of symmetry. In the next section we will see that for the map of the genetic code we have a similar situation — this map is locally constant but this local constancy can not be described by a natural symmetry.

### 4 2-Adic parametrization of the genetic code

In the 2-adic parametrization approach of [7] we enumerate in some special way the set of 64 codons (triples of nucleotides) by pairs of digits $(x, y)$, $x, y = 0, 1, 2, \ldots, 7$. These digits are in one to one correspondence with the triples $(x_0, x_1, x_2)$ and $(y_0, y_1, y_2)$ of 0 and 1 (the expansions of $x$ and $y$ over degrees of 2):

$$x = x_0 + 2x_1 + 4x_2, \quad y = y_0 + 2y_1 + 4y_2, \quad x_1, y_1 = 0, 1.$$
2-Adic norm of $x$ is equal to $2^{-i}$, where $i$ is the number of the first non zero $x_i$ in the above expansion (analogously for $y$).

Each pair of digits $(x_i, y_i)$ is defined by a nucleotide using the rule

$$
\begin{array}{cc}
A & G \\
U & C
\end{array} = \begin{array}{c}
00 \\
10
\end{array} \begin{array}{c}
01 \\
11
\end{array}
$$

Since the nucleotides $A = (0,0)$ and $G = (0,1)$ are purines, $U = (1,0)$ and $C = (1,1)$ are pyrimidines, the different first digits in the above binary representation corresponds to the different chemical types of the nucleotides. Namely, the nucleotide $(x, y)$ with $x = 0$ is a purine, and the nucleotide $(x, y)$ with $x = 1$ is a pyrimidine.

The second digit $y = 0, 1$ in the considered parametrization describes the $H$-bonding character (weak for $y = 0$ and strong for $y = 1$).

Using the above correspondence between the nucleotides and the digits 0 and 1, we introduce the correspondence between the codons (triples of nucleotides) and the triples $(x_0, x_1, x_2)$ and $(y_0, y_1, y_2)$ of 0 and 1 (equivalently, the corresponding $x, y = 0, 1, 2, \ldots, 7$) by the following prescription.

The second nucleotide in the codon defines the pair $(x_0, y_0)$, the first nucleotide in the codon defines the pair $(x_1, y_1)$, and the third nucleotide in the codon defines the pair $(x_2, y_2)$.

This rule is related to the following hierarchy of nucleotides in the codon

$$2 > 1 > 3$$

i.e the second nucleotide in the codon is the most important (and the largest in the 2-adic norm) and the third nucleotide is the least important.

After that we make the special reordering of the values of $x$ and $y$:

$$0, 4, 2, 6, 1, 5, 3, 7 \mapsto 1, 2, 3, 4, 5, 6, 7, 8.$$ similar to made in [26].

Then we enumerate codons using the described above rule. Namely we put the codons in the table $8 \times 8$ with the natural 2-adic norm (here the numbers of the lines and columns are $x$ and $y$ defined above):

\[
\begin{array}{cccccccc}
AAA & AAG & GAA & GAG & AGA & AGG & GGA & GGG \\
AAU & AAC & GAU & GAC & AGU & ACC & GGU & GGC \\
UAA & UAG & CAA & CAG & UGA & UGG & CGA & CGG \\
UAU & UAC & CAU & CAC & UGU & UGC & CGU & CGC \\
AUA & AUG & UUA & UUG & CAU & CUG & UCA & UCG \\
AUU & AUC & UUU & UUC & ACU & ACC & UCU & UCC \\
\end{array}
\]

The $2 \times 2$ quadrates here are 2-dimensional 2-adic balls (or clusters) of the diameter $1/4$.

After application of the eucaryotic genetic (amino acid) code (described in the Appendix) to the above table we get the table of amino acids on the 2-adic plane

\[
\begin{array}{cccc}
K & E & R & G \\
N & D & S & P \\
\end{array}
\begin{array}{cccc}
Y & Q & W & R \\
H & U & C & A \\
\end{array}
\]

where Ter is the stop codon. Each square in the above table is the 2 by 2 square in the 2-adic plane of codons. In particular, the genetic code map acts as follows on the 2-adic balls

$$\begin{array}{cc}
AAA & AAG \\
AAU & AAC
\end{array} \mapsto \begin{array}{cc}
K & N \\
CCA & CCG
\end{array} \mapsto \begin{array}{cc}
CCU & CCC
\end{array}$$

6
Here we use the standard notations for the nucleotides A, U, G, C and the amino acids.

We see, that the degeneracy of the genetic code in the above 2-adic parametrization is described by the 2-adic proximity — the codons which encode the same amino acid are 2-adically close. Moreover, the domains with the different degeneracy are symmetric at the 2-adic plane — the lower right half of the plane is occupied by amino acids with the degeneracy four, and the upper left half of the plane contains the amino acids with the degeneracy mainly equal to two. We also have the five cases of additional degeneracy which is not described by the 2-adic parametrization.

The described here 2-adic 2-dimensional parametrization of the genetic code is related to physical–chemical properties of the amino acids. Namely, the hydrophobic amino acids are clustered in the following two 2-adic balls in the 2-adic plane:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>M</td>
<td>I</td>
</tr>
<tr>
<td>L</td>
<td>F</td>
<td>L</td>
</tr>
</tbody>
</table>

Here the hydrophobic amino acids are listed according to the book [38].

Using the 2-adic parametrization of the genetic code we can divide all the set of amino acids in the groups \{K, N, E, D, Y, Q, H\}, \{R, G, W, C\}, \{I, M, V, L, F\}, \{T, A, S, P\}. These groups are the images with respect to the map of the genetic code of the four quadrants (2-adic balls of the diameter 1/2) of the 2-adic plane of codons.

5 The PAM matrix

The following table describes the PAM250 matrix, see the Appendix for the definition:

\[
A = \begin{bmatrix}
\ast & A & C & D & E & F & G & H & I & K & L & M & N & P & Q & R & S & T & V & W & Y \\
A & 2 & -2 & 0 & 0 & -4 & 1 & -1 & -1 & -1 & -2 & -1 & 0 & 1 & 0 & -2 & 1 & 0 & -6 & -3 \\
C & * & 12 & -5 & -5 & -4 & -3 & -3 & 2 & -5 & -6 & -5 & -4 & -3 & -5 & -4 & 0 & -2 & -8 & 0 \\
D & * & * & 4 & 3 & -6 & 1 & 1 & 2 & 0 & -4 & -3 & 2 & -1 & 2 & -1 & 0 & 0 & -2 & 7 & -4 \\
E & * & * & * & 4 & -5 & 0 & 1 & -2 & 0 & -3 & -2 & 1 & -1 & 2 & -1 & 0 & 0 & -2 & 7 & -4 \\
F & * & * & * & * & 9 & 5 & 2 & -1 & -5 & 2 & 0 & -4 & -5 & -5 & -4 & -3 & -3 & 1 & 0 & 7 \\
G & * & * & * & * & * & 5 & 2 & -3 & -2 & -4 & -3 & 0 & -1 & -1 & -3 & 1 & 0 & -1 & 7 & -5 \\
H & * & * & * & * & * & * & 6 & -2 & 0 & -2 & -2 & 2 & 0 & 3 & 2 & -1 & -1 & -2 & 3 & 0 \\
I & * & * & * & * & * & * & * & 5 & -2 & 2 & 2 & -2 & -2 & -2 & -1 & 0 & 4 & -5 & -1 \\
K & * & * & * & * & * & * & * & * & 5 & -3 & 0 & 1 & -1 & 1 & 3 & 0 & 0 & -2 & 3 & -4 \\

\end{bmatrix}
\]

Because the matrix \(A\) is symmetrical we put only the half of matrix elements. This matrix looks irregular and has no any obvious structure. In the next Section we will show that some reordering of the numbers of the lines and columns will put this matrix in more regular form.
6 Reordering of matrix elements of the PAM matrix

Let us enumerate the lines and the columns of the PAM matrix $A$ of the previous Section using the 2-adic parametrization of the genetic code. We get for $A$ the following:

$$A = \begin{pmatrix}
5 & 1 & 0 & 0 & -4 & 1 & 0 & 3 & -2 & -3 & -5 & -2 & 0 & -2 & -3 & -5 & 0 & -1 & 0 & -1 \\
N & 1 & 2 & 1 & 2 & -1 & 2 & 0 & 0 & -4 & -4 & -2 & -2 & -2 & -3 & -4 & 0 & 0 & 1 & -1 \\
E & 0 & 1 & 4 & 3 & -4 & 2 & 1 & -1 & 0 & -7 & -5 & -2 & -2 & -2 & -3 & -5 & 0 & 0 & 0 & -1 \\
D & 0 & 2 & 3 & 4 & -4 & 2 & 1 & -1 & 1 & -7 & -5 & -2 & -3 & -2 & -4 & -6 & 0 & 0 & 0 & -1 \\
Q & 1 & 1 & 2 & 2 & -4 & 4 & 3 & 1 & -1 & -5 & -5 & -2 & -1 & -2 & -2 & -5 & -1 & 0 & -1 & 0 \\
H & 0 & 2 & 1 & 1 & 1 & 0 & 3 & 6 & 2 & -2 & -3 & -3 & -2 & -2 & -2 & -2 & -1 & -1 & -1 & 0 \\
R & 3 & 0 & -1 & -1 & -4 & 1 & 2 & 6 & -3 & 2 & -4 & -2 & 0 & -2 & -3 & -4 & -1 & -2 & 0 & 0 \\
G & -2 & 0 & 0 & 1 & -5 & -1 & -2 & -3 & 5 & -7 & -3 & -3 & -3 & -1 & -4 & -5 & 0 & 1 & 1 & -1 \\
W & -3 & -4 & -7 & -7 & 0 & -5 & -3 & 2 & -7 & 17 & -8 & -5 & -4 & -6 & 2 & 0 & 5 & -6 & -2 & -6 \\
T & 0 & 0 & 0 & 0 & -3 & -1 & -1 & -1 & 0 & -5 & -2 & 0 & -1 & 0 & 2 & -3 & 3 & 1 & 1 & 0 \\
A & -1 & 0 & 0 & 0 & -3 & 0 & -1 & -2 & 1 & 1 & 6 & -2 & -1 & 1 & 0 & -2 & -4 & 1 & 2 & 1 \\
S & 0 & 1 & 0 & 0 & -3 & -1 & -1 & 0 & 1 & -2 & 0 & -1 & 2 & -6 & -3 & -3 & 1 & 1 & 2 & 1 \\
P & -1 & -1 & -1 & -1 & -5 & 0 & 0 & 0 & 0 & -1 & -6 & -3 & 2 & -2 & -1 & -3 & -5 & 0 & 1 & 1 & 6
\end{pmatrix}
$$

Here we divided all the set of amino acids to the groups $\{K, N, E, D, Y, Q, H\}$, $\{R, G, W, C\}$, $\{I, M, V, L, F\}$, $\{T, A, S, P\}$. These four groups correspond to the second nucleotide in the codons which encode (through the amino acid genetic code) amino acids in the corresponding group. Namely, the first group correspond to the codons with A (Adenine) at the second position, the second group correspond to the codons with G (Guanine), the third group correspond to the codons with U (Uracil), and the fourth group correspond to the codons with C (Cytosine).

Compared to the PAM matrix from the previous Section, this reshuffled matrix is more regular. It has large positive matrix elements at the main diagonal, and off diagonal terms are close to block constant at least at some of the 16 blocks, corresponding to matrix elements with the indices from one of the 4 groups of amino acids.

In particular, in the block corresponding to the matrix elements $A_{ij}$, $i,j \in \{T, A, S, P\}$, all off diagonal matrix elements are equal to 1 (10 matrix elements) or 0 (2 matrix elements).

In the block $A_{ij}$, $i \in \{K, N, E, D, Y, Q, H\}$, $j \in \{T, A, S, P\}$ we have matrix elements equal to 0 (13 matrix elements), $-1$ (10 matrix elements), 1 (1 matrix element) and anomalous matrix elements equal to $-3$ and $-5$ corresponding to the amino acid Y. The analogous situation we will have in the other blocks of the matrix $A$.

We arrive to the following picture: the PAM matrix $A$ will be a block matrix with matrix elements close to locally constant (i.e. constant in the 16 blocks) if we will exclude matrix elements corresponding to some amino acids, namely, to the amino acids Y, W, C, L, F, and R.

7 Expansion for the PAM matrix

In the present Section we introduce the main construction of this paper: we will expand the PAM matrix $A$ in the sum of the matrices $A^{(2)}$ and $A^{(\infty)}$:

$$A = A^{(2)} + A^{(\infty)},$$

where the matrix $A^{(2)}$ will be 2-adically regular (matrix elements are close to locally constant), and the matrix $A^{(\infty)}$ will be sparse (i.e. majority of matrix elements of this matrix will be equal to zero).
We propose the following choice for matrices $A^{(2)}$ and $A^{(\infty)}$.

$$A^{(2)} = \begin{pmatrix}
K & 5 & 1 & 1 & 1 & 1 & 0 & -1 & -2 & -1 & -1 & -2 & -2 & -2 & -2 & 0 & -1 & 0 & 1 \\
N & 1 & 2 & 1 & 2 & 1 & 1 & 2 & 0 & 0 & 0 & 0 & -2 & -2 & -2 & -2 & 0 & 0 & 0 \\
E & 1 & 1 & 4 & 3 & 1 & 2 & 1 & -1 & 0 & -1 & -1 & -2 & -2 & -2 & -2 & 0 & 0 & 0 \\
D & 1 & 2 & 3 & 4 & 1 & 2 & 1 & -1 & 0 & -1 & -1 & -2 & -3 & -2 & -2 & 0 & 0 & 0 \\
Y & 1 & 1 & 1 & 1 & 1 & 0 & 1 & -1 & 0 & -1 & 0 & -1 & -2 & -2 & -1 & -1 & -1 \\
Q & 1 & 1 & 2 & 2 & 1 & 4 & 3 & -1 & -1 & -1 & -1 & -2 & -1 & -2 & -2 & -1 & 0 & 1 \\
H & 0 & 1 & 2 & 1 & 1 & 0 & 3 & 6 & -1 & -2 & -1 & -1 & -2 & -2 & -2 & -1 & -1 & 0 \\
G & -2 & 0 & 0 & 0 & -1 & -1 & -2 & -3 & 5 & -3 & -3 & -3 & -3 & -1 & -2 & -3 & 0 & 1 & 1 \\
W & -1 & 0 & -1 & -1 & 0 & -1 & -1 & 2 & -3 & -3 & -3 & -3 & -3 & -1 & -2 & -3 & -2 & 2 & -2 \\
T & 0 & 0 & 0 & 0 & -1 & -1 & 1 & -1 & 0 & -1 & -2 & 2 & 2 & 2 & 2 & 0 & 1 & 1 & 2 & 2 \\
A & 0 & 0 & 0 & 0 & -1 & 0 & 1 & -2 & -1 & -2 & 2 & 2 & 2 & 2 & 2 & 0 & 1 & 1 & 2 & 2 \\
S & 0 & 0 & 0 & 0 & -1 & 0 & 1 & -2 & -1 & -2 & 2 & 2 & 2 & 2 & 2 & 0 & 1 & 1 & 2 & 2 \\
P & 0 & 0 & 0 & 0 & 0 & -1 & -2 & -3 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 0 & 1 & 1 & 2 & 2 \\
\end{pmatrix}$$

$$A^{(\infty)} = \begin{pmatrix}
K & 0 & 0 & -1 & -1 & -5 & 0 & 0 & 4 & 0 & 2 & 2 & 0 & 0 & -1 & -3 & 0 & 0 & 0 & 0 \\
N & 0 & 0 & 0 & 0 & -3 & 0 & 0 & 4 & 0 & 2 & 2 & 0 & 0 & -1 & -3 & 0 & 0 & 0 & 0 \\
E & -1 & 0 & 0 & 0 & -5 & 0 & 0 & 0 & 0 & 4 & 0 & 0 & 0 & 0 & -3 & 0 & 0 & 0 & 0 \\
D & -1 & 0 & 0 & 0 & -5 & 0 & 0 & 0 & 0 & 4 & 0 & 0 & 0 & 0 & -3 & 0 & 0 & 0 & 0 \\
Y & 0 & 0 & 0 & 0 & -5 & 0 & 0 & 2 & 0 & 4 & 4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
Q & 0 & 0 & 0 & 0 & -5 & 0 & 0 & 2 & 0 & 4 & 4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
H & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 3 & 0 & -2 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
R & 4 & 0 & 0 & 0 & -3 & 3 & 3 & 0 & 0 & 4 & 2 & 2 & 2 & 0 & 1 & -2 & 0 & 0 & 0 \\
G & 0 & 0 & 0 & 1 & -4 & 0 & 0 & 0 & 0 & -4 & 2 & 4 & 4 & 4 & -5 & 3 & -2 & 4 & 0 \\
W & -2 & -4 & -6 & -6 & 0 & -4 & 2 & 4 & 4 & 0 & -5 & 3 & -2 & -4 & 0 & 2 & 3 & 0 & 4 & 4 \\
C & -4 & -4 & -4 & -4 & 0 & -4 & -2 & 4 & 4 & 0 & -5 & 3 & -2 & -4 & 0 & 2 & 3 & 0 & 4 & 4 \\
I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
M & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & -2 & -3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
V & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
L & -1 & -1 & 1 & 2 & 0 & 0 & 0 & -1 & 0 & -4 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
F & -3 & 2 & 3 & 4 & 9 & -3 & 0 & -2 & -2 & 2 & 2 & -1 & -2 & 0 & 0 & -2 & -3 & -1 & -3 \\
T & 0 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & -3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
A & 0 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
S & 0 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
P & 0 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & -4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}$$

Non zero matrix elements of $A^{(\infty)}$ are mainly concentrated on the lines and columns corresponding to Y, W, C, L, F. There are also several non-zero matrix elements corresponding to R and some other amino acids.

We see that the non zero matrix elements of $A^{(\infty)}$ are mainly concentrated on aromatic amino acids, such as Y, F, W, and on C which contains the SH group. Therefore deviations from 2-adic regularity (i.e. the block structure of the $A^{(2)}$ matrix) can be discussed as related to the geometric properties of the side chains of amino acids (for aromatic amino acids Y, F, W, and for Arginine R), and to the ability of Cysteine C to create a disulfide bond.
The above picture shows the amino acids W, F, Y corresponding to non-zero matrix elements of the matrix $A^{(\infty)}$. Let us mention that amino acids F and Y for which the corresponding matrix element $A_{FY}^{(\infty)}$ is very large (and majority of the other matrix elements of $A^{(\infty)}$ for these amino acids are negative) are very similar from the point of view of geometry. Therefore the sparse part $A^{(\infty)}$ of the PAM matrix can be discussed as the contribution to the PAM matrix related to the geometric properties of the amino acids (and to disulfide bonds of Cysteine).

The 2-adically regular part $A^{(2)}$ of the PAM matrix is related to chemical properties of the amino acids such as hydrophobicity. In [7] it was shown that the hydrophobic amino acids are clustered in the 2-adic metric.

The obtained expansion (4) of the PAM matrix can be used as follows. Let us define the matrix

$$A(\alpha, \beta) = \alpha A^{(2)} + \beta A^{(\infty)}, \quad \alpha, \beta \geq 0.$$ 

In particular, $A(1, 1)$ is equal to the PAM matrix.

The matrix $A(\alpha, \beta)$ matrix might be considered as a substitution matrix for some alignment procedure. Varying the parameters $\alpha$ and $\beta$, one could consider alignments where the different (chemical or geometrical) properties of amino acids are taken into account.

Of course, our analysis of PAM matrix based on the 2-adic plane representation of the genetic code is only the first step in using $p$-adic numbers in genetics and bioinformatics in general. We hope to proceed towards other important problems, cf., e.g., [12]– [15], [39]. Finally, we mention the famous ”In Silico Biology” project, see, e.g., Yamato et al. [40]. We point out that, in fact, operation of any computer can be represented as 2-adic dynamical system, see [21], [41]. Therefore 2-adic representation of the genetic code might be useful in realization of the ”In Silico Biology” project.

8 Appendix: the PAM matrix

In this section we discuss the construction of the Dayhoff PAM matrix, which can be found for example in [12, 13]. We start with blocks — ungapped multiple alignments of proteins from existing databases. Any sequence in the block is no more than 15% different from any other sequence in this block.

Then, the Markov model, which reproduces the mentioned blocks of proteins was constructed. This Markov model is defined by the amino acid substitutions (point mutations). We have the stationary distribution $p_a$ of the probabilities of the amino acids, $\sum_{a=1}^{20} p_a = 1$, and the transition probability $p_{ab}$, normalized by the condition that the probability of a point mutation (substitution of the amino acid) at one step of the Markov model is equal to 0.01:

$$\sum_{a,b=1}^{20} p_{ab} p_b = 0.01.$$

Then we take the matrix given by the $n$ steps of the Markov model, i.e. the $n$-th degree $P^n$ of the matrix $P = (p_{ab})$, and consider the matrix with the matrix elements

$$(A_n)_{ab} = \log_{10} \left( \frac{(P^n)_{ab}}{p_b} \right).$$
This matrix is known as the PAM matrix (usually $n$ is taken to be equal to 250 and the matrix elements are approximated by integers).

9 Appendix: the genetic code

The following table describes the eucaryotic genetic code — the correspondence between codons (triples of nucleotides and amino acids):

<table>
