Title: Assessing variety and pricing of selected foods in socioeconomic disparate districts of Berlin, Germany

Article Type: Original Article

Corresponding Author: Dr. Nanette Stroebele, PhD

Corresponding Author's Institution: Charité University Medical Centre, Berlin, Germany

First Author: Nanette Stroebele, PhD

Order of Authors: Nanette Stroebele, PhD; Pia Dietze; Peter Tinnemann, Dr. med.; Stefan N Willich, Prof

**Abstract:** **Aim:** The neighbourhood environment appears to influence people's food consumption. Access, variety and pricing of foods play a role in the socioeconomic difference of fruit and vegetable consumption. This study compared differences in number of grocery stores, variety of fresh fruits and vegetables and food prices in districts with different Social Index (SI) in Berlin, Germany. **Methods:** The district with the lowest SIs was compared to the district with the highest SI. The number of grocery stores offering fresh produce, the variety of fresh fruits and vegetables, and prices of selected healthy and less healthy food items were assessed and compared. **Results:** The low SI district had more grocery stores per residents than the high SI district. Variety and prices of fruits and vegetables did not differ between the two districts but milk and whole wheat bread were less expensive in the high SI district. For all grocery stores, selected foods with higher energy density had lower energy costs than low energy density foods. **Conclusion:** Health inequalities in Germany might be less influenced by access to healthy foods than in other countries but nutrient rich foods such as fruits and vegetables have higher energy costs than high energy dense foods.

Response to Reviewers: Response to reviewer's comments:

The authors provide no explanation why cigarettes are included in the study, which deals with pricing of food. Cigarettes don't belong to any group of food, so it has to be explained why they are analysed in this context as well.

- The authors have decided to exclude the item "cigarettes" from the analysis and the manuscript. The authors agree with the reviewer that the topic of cigarette pricing and its relationship to socioeconomic differences does not belong in this manuscript.

p. 2, 1st paragraph: ". behaviour. ", should use similar terms as in the rest of the text.

- The British orthography was used and all words were changed accordingly.

p. 5, 1st paragraph: The two areas Kreuzberg and Steglitz-Lankwitz are compared, but the population density is given for the three areas: Kreuzberg, Steglitz and Lankwitz. This is confusing and should be clarified.

- Official data only provides population density separately for Steglitz and Lankwitz but the authors hopefully clarified this confusion by calculating the mean for both areas.

p. 5, 1st paragraph and p. 9, 3rd paragraph: information about the size of the two areas is inconsistent: p.5 ". roughly the same size. ", p. 9 ". size. differed."

- The information regarding the size of the areas chosen was clarified.

p. 5, 3rd paragraph: It should be explained in this paragraph why the variety of food items was determined only in non-organic food stores (compare p.6, 1st paragraph).

- A sentence explaining the reasons for choosing only non-organic food stores was added (p. 5, 3rd paragraph)

p. 6, 1st paragraph: Which established criteria for the popularity for the chosen food products in the German population were used?

- A reference was added.

p. 7, 1st paragraph: ". framers' markets. ", should use similar terms as of the rest of the text.

- For all markets, the expression "farmers' markets" was chosen.

p. 8, 2nd paragraph: The relationship between energy density and energy costs should be explained shortly in the part "results", only referring to the figure would not be sufficient.

- The results presented in figure 1 were explained in more details (p. 8, 2nd paragraph).

p. 9, last paragraph and p. 11, 1st paragraph are identical.

- The last paragraph on page 9 was taken out.

**Assessing variety and pricing of selected foods in socioeconomic disparate districts of Berlin, Germany.**

4 **Introduction**  
5

6 Unhealthy dietary behaviour, in particular the consumption of fruits and vegetables has been  
7 shown to be particularly low among socioeconomically disadvantaged populations (Giskes et al.  
8 2002; Hulshof et al. 2003). A systematic review revealed that household income appears to be  
9 consistently positively related to fruit and vegetable intake (Kamphuis et al. 2006) and lower  
10 socioeconomic groups seem to be less likely to follow existing dietary guidelines (Turrell et al.  
11 2002).  
12  
13  
14  
15  
16  
17  
18  
19  
20

21 Another factor that has been gaining attention recently is the possible influence of  
22 neighbourhood food environment. Recent studies from the U.S. suggest that residents of  
23 socioeconomically disadvantaged neighbourhoods have less access to affordable healthy food  
24 choices compared to high socioeconomic neighbourhoods (Jetter et al. 2006; Hendrickson et al.  
25 2006; Chung et al. 1999; Moore et al. 2006; Powell et al. 2007; Zenk et al. 2009). Healthier food  
26 choices in deprived areas differ in their availability, variety and in price compared to healthier  
27 choices in less deprived areas. In deprived areas fewer variety of fresh fruits and vegetables is  
28 offered and fresh produce tend to be more expensive (Hosler et al. 2008; Zenk et al. 2005).  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41 However, other studies show few or no differences in food prices, availability or access between  
42 deprived and affluent areas (Cassady et al. 2007; Smith et al. 2009; Winkler et al. 2006a;  
43 Winkler et al. 2006b). Two recent systematic reviews examining the empirical evidence found  
44 only little evidence for the influence of environmental factors on fruit and vegetable  
45 consumption (Giskes et al. 2007; Kamphuis et al. 2007).  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

66 Another aspect of the food environment has been gaining attention in the public health sector;  
67 high energy dense foods, high fat foods and general convenience, processed foods including fast  
68

1  
2  
3  
4 food tend to be cheaper than healthy foods such as fresh fruits or vegetables (Drewnowski et al.  
5  
6 2004; Darmon et al. 2004). Research on dietary behaviour and social inequalities suggest that  
7  
8 low income households rather purchase energy dense foods that are nutrient poorer but are at an  
9  
10 affordable cost compared to more expensive nutrient rich foods such as fresh fruits and  
11  
12 vegetables (Drewnowski et al. 2005; Drewnowski 2009). Data from the U.S. shows an inverse  
13  
14 relationship between the energy density of foods and the energy costs measured in  
15  
16 USD/1000kcal (Drewnowski et al. 2005). It is possible that lower food costs might be associated  
17  
18 with higher energy dense diets which might lead to an increase in total energy intake. As a  
19  
20 consequence, the higher prevalence of overweight and obesity in socio-economically  
21  
22 disadvantaged groups could be explained by this imbalance of economics of food choice.  
23  
24  
25

26  
27 Research in the area of food environment and social inequality in Germany is lacking.  
28  
29

30  
31 Although socioeconomic inequalities is less pronounced in Germany compared to other countries  
32  
33 (van Doorslaer et al. 2004; Hernandez-Quevedo et al. 2006), prior research has shown that  
34  
35 people of low economic standing in Germany have above average rates of malnutrition, eating  
36  
37 disorders and obesity (Mackenbach et al. 2008; Robert Koch-Institut 2006). The capital city of  
38  
39 Germany, Berlin, consists of a number of districts where inhabitants live under conditions  
40  
41 differing widely by their socioeconomic situation such as income, unemployment rate, and ethnic  
42  
43 background as well as in their health and disease status (Senatsverwaltung für Gesundheit 2009).  
44  
45  
46  
47

48  
49  
50 In this pilot study, we sought to determine if differences in the food neighbourhood environment  
51  
52 are apparent in Berlin, Germany. We analyzed the two districts with the largest social economic  
53  
54 disparity and studied their availability of stores, produce prices and fruit and vegetable variety.  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

## Methods

This study investigated access to food within two districts in Berlin comparing the districts with the lowest and highest socioeconomic population. The study examined (1) the number of grocery stores offering fresh produce; (2) the variety of fresh fruits and vegetables available to the consumers; and (3) the prices of a series of food items defined as healthy and unhealthy. Healthy food items included a series of popular fresh fruits and vegetables, milk and whole-wheat bread. As unhealthy, energy dense food items, such as frozen pizza, chocolate, and potato chips were chosen.

### *Setting*

Two areas in Berlin similar in size but with a widely different socioeconomic population were selected. The socioeconomic difference between the two areas was determined by a complex measuring tool called the Social Index (SI) created by the city of Berlin (Senatsverwaltung für Gesundheit 2009). The SI was developed to determine social differences between Berlin's neighbourhoods and to create a common ground for analysis and planning of social communities. Among other things, the index is based on unemployment rates, average per capita income, number of people on social welfare, and life span expectancy. We chose to study the area of Kreuzberg which lies within the community district of Kreuzberg-Friedrichshain and represents the neighborhood with one of lowest SI in Berlin based on the SI of 2008. The other area chosen was Steglitz and Lankwitz which is an area within the community district of Steglitz-Zehlendorf. Steglitz-Zehlendorf represents the neighborhood with the highest SI in Berlin in 2008. The net household income in Kreuzberg-Friedrichshain in 2006 was € 1,175 per months whereas the net household income in Steglitz-Zehlendorf was € 1,850. The areas are roughly of the same size

1  
2  
3  
4 (10.4 km<sup>2</sup> for Kreuzberg and 13.8 km<sup>2</sup> for Steglitz and Lankwitz) but population density is  
5  
6 higher in Kreuzberg (14.239 residents/km<sup>2</sup>) compared to Steglitz and Lankwitz (8.085  
7  
8 residents/km<sup>2</sup>; Steglitz is 10.391 residents/km<sup>2</sup> and Lankwitz is 5.778 residents/km<sup>2</sup>).  
9  
10

### 11 12 13 14 *Availability*

15  
16 Within the districts the number of food stores including organic grocery stores and farmers'  
17  
18 markets were counted. Food stores were identified through systematic investigation of each and  
19  
20 every street within the established district borders. Farmers' markets were located through  
21  
22 internet research. Food stores were defined as stores that offer at least one type of fresh vegetable  
23  
24 and one type of fresh fruit (except lemons or limes). Food stores had to be open at least 5  
25  
26 days/week for 8 hours/day. Farmers' markets were included if they were open for at least 6  
27  
28 hours/week. Availability was defined as the number of food stores and farmers' markets per  
29  
30 10.000 residents.  
31  
32  
33  
34  
35  
36  
37

### 38 *Variety of fresh fruits and vegetables within food stores*

39  
40 Variety of food items was determined through the visual count of different kinds of fresh fruit  
41  
42 and vegetables available at each store by a trained surveyor to all non-organic food stores during  
43  
44 the months of May through July 2009. Given that organic food stores are still relatively rare as  
45  
46 well as usually limited in their fruit and vegetable variety, only non-organic food stores and  
47  
48 foods were assessed. The following fresh fruit and vegetable items were summarized into larger  
49  
50 categories and counted as one: berries (strawberries, cranberries, raspberries, blackberries),  
51  
52 lemon (lemon and limes), melons (watermelons, cantaloupes, honeydew), and cabbage (red  
53  
54 cabbage, green cabbage, chinese cabbage). To control for seasonal variation and to increase  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 comparability, we collected data concurrently in both districts and completed data collection  
5  
6 within 12 weeks.  
7  
8  
9

### 10 11 *Pricing* 12

13  
14 For the purpose of price comparison between stores and districts, the most economical price for a  
15  
16 sample of 12 products was recorded. The 12 products were chosen because of their popularity  
17  
18 among the German population (DFHV, 2009). Food prices of the following 12 food products  
19  
20 were measured: apples, bananas, tomatoes, carrots, potatoes, whole wheat bread, fresh milk,  
21  
22 frozen pizza, chocolate, potato chips, and beer. Since the most economical price for each food  
23  
24 was often found in bulk quantities we calculated prices for predetermined amounts. Prices for  
25  
26 fresh fruit and vegetable items were noted per one kilogram (1000 grams). Prices for whole  
27  
28 wheat bread, chocolate and chips were recorded per 100 grams. Fresh milk prices were recorded  
29  
30 as price per carton (1 liter), beer prices as the cost per 0.5 liter, and frozen pizza as price for one  
31  
32 pizza (300 grams). Organic food stores were not entered to record prices or produce variety  
33  
34 because high quality standards often cause costs to increase which makes sold items  
35  
36 unaffordable to many people and high prices would result in distorted price averages.  
37  
38  
39  
40  
41  
42  
43  
44

### 45 46 *Statistical Analysis* 47

48 Analysis of variance was used to examine differences by district (low SI vs. high SI) in the mean  
49  
50 number of fruits and vegetables and the mean lowest prices of the selected food items available  
51  
52 in all stores. Using the average caloric content of selected food items (100g pizza = ca. 216kcal,  
53  
54 100g potato chips = ca. 547 kcal, 100g chocolate = ca. 536 kcal, 100g apples = ca. 49 kcal, 100g  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 bananas = ca. 95 kcal, 100g carrots = ca. 25 kcal), the relationship between energy costs (Euro  
5  
6 €/1,000 kcal) and energy density (kcal/g) of each food item was calculated.  
7  
8  
9

## 10 11 **Results**

12  
13  
14 The low SI district (Kreuzberg) had greater access to supermarkets compared to the district with  
15  
16 high SI (Steglitz + Lankwitz). Per 10,000 residents, in the low SI district 5.88 food stores  
17  
18 (including farmer markets and organic food stores; N = 87) were available compared to only 4.42  
19  
20 food stores in the high SI district (N = 46). More organic food stores and farmers' markets were  
21  
22 available in the low SI area compared to the high SI area.  
23  
24  
25  
26  
27

28  
29 Number of types of fruits and vegetables in the low SI district did not differ significantly from  
30  
31 the number of types of fruits and vegetables in the high SI district (table 1).  
32  
33  
34  
35

36 - insert table 1 -  
37  
38  
39

40  
41 In the low SI district, prices of the selected food items were assessed in 72 grocery stores  
42  
43 including 13 supermarkets, 23 discounters, and 36 farmers' markets. In the high SI district only  
44  
45 45 grocery stores including 18 supermarkets, 18 discounters, and nine farmers' markets were  
46  
47 found. Including all types of food stores (super markets, discounters and farmers' markets) fruits  
48  
49 and vegetables did not differ in pricing between the two districts. No differences were found for  
50  
51 apples, bananas, tomatoes, carrots and beer. Potatoes (F= 9,122, p= 0.003), whole-wheat bread  
52  
53 (F= 9,527, p = 0.003), fresh milk (F= 56,179, p = 0.000), chocolate (F= 40,489, p = 0.000),  
54  
55 potato chips (F= 32,655, p = 0.000), and frozen pizza (F= 5,819, p = 0.018) were significantly  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 cheaper in the high SI district compared to the low SI district (table 1). However, when the local  
5  
6 farmers' markets which were more common in the low SI district were taken out of the analysis,  
7  
8 the only four remaining items that were less expensive in the high SI district were whole-wheat  
9  
10 bread (0,16 vs. 0,14; F=20,208, p = 0.000), fresh milk (0,50 vs. 0,48; F= 6,634, p= 0.012), and  
11  
12 potato chips (0,29 vs. 0,28; F = 6,081, p = 0.016). Without the farmers' markets, bananas were  
13  
14 cheaper in the low SI district compared to the high SI district (1,18 vs. 1,13; F= 10,589, p =  
15  
16 0.002).  
17  
18  
19  
20  
21  
22

23  
24 To compare pricing of selected low and high energy dense foods, the mean prices of all grocery  
25  
26 stores for the following food items were chosen: chocolate, potato chips, pizza, apples, bananas  
27  
28 and carrots. Figure 1 shows the relationship between energy density (kcal/g) and energy costs  
29  
30 (Euro€/1,000kcal) of a selection of low and high energy dense foods. It shows that energy costs  
31  
32 for apples (3,26€/1,000kcal), bananas (4,10€/1,000kcal), and carrots (4,88€/1,000kcal) are higher  
33  
34 than for pizza (2,16€/1,000kcal), potato chips (0,84€/1,000kcal), and chocolate (0,66€/1,000kcal)  
35  
36 whereas energy density is higher for pizza (2,16kcal/g), potato chips (5,47kcal/g), and chocolate  
37  
38 (5,36kcal/g) compared to apples (0,49kcal/g), bananas (0,95kcal/g) and carrots (0,25kcal/g).  
39  
40  
41  
42  
43  
44

45  
46 - insert figure 1 -  
47

## 48 **Discussion**

49

50  
51 The variety and prices of the examined food items were similar in the high and low  
52  
53 socioeconomic districts. More grocery stores per 10.000 residents were found in the low SI area  
54  
55 compared to the high SI area. The variety of fruits and vegetables did not differ between the  
56  
57 districts and no differences could be found in terms of fruit and vegetable prices. These findings  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 are in line with several other studies (Smith et al. 2009; Zenk et al. 2009; Cassady et al. 2007) .  
5  
6 However, other food items such as fresh milk and whole wheat bread tended to be cheaper in the  
7  
8 high SI district which in part supports the idea that healthy food choices tend to be more  
9  
10 expensive in more disadvantaged neighbourhoods.  
11  
12

13  
14 Looking at high-fat/energy-dense foods such as pizza, potato chips and chocolate significantly  
15  
16 higher prices were observed in the low SI neighborhood. A possible explanation for the higher  
17  
18 prices could be that grocery stores simply sell some of products at a higher price in  
19  
20 neighbourhoods with a higher demand for these types of foods and products. Since this effect is  
21  
22 mainly observed for unhealthy food items and not for fruits and vegetables it raises the question  
23  
24 of the possibility of existing health inequity based on socio-economic standing.  
25  
26  
27  
28  
29

30  
31 In general, food pricing in Germany appears to be similar to food pricing in other nations with  
32  
33 energy dense foods to be the lowest cost dietary options. For people with low SI, the financial  
34  
35 aspect of foods most likely plays a crucial role in their purchase behaviour.  
36  
37  
38  
39

#### 40 *Limitations of this study*

41  
42 Several limitations of this study need to be mentioned. This was a pragmatic case-study approach  
43  
44 with the focus on two geographically comparable areas in one particular city. Mainly the  
45  
46 population density between the two districts differed. This approach does not allow the  
47  
48 comparison of associations between neighbourhood deprivation and food accessibility for the  
49  
50 full range of urban and rural settings across the world or even across Germany only.  
51  
52

53  
54 The findings of this study can only be generalized to the study region and spatial inequality  
55  
56 might exist in rural and small town settings in Germany. In addition, no information on  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 residents' shopping behaviours was obtained and food quality was also not addressed. Other food  
5  
6 outlets such as convenience stores without fresh fruits and vegetables, restaurants, snack bars  
7  
8 that might play a role in determining food item pricing were also not examined.  
9

### 10 11 12 13 14 *Possible Implications and future research*

15  
16 To our knowledge, this is the first study in Germany looking at neighbourhood food  
17  
18 environments. The findings showed that the food environment in a socioeconomically  
19  
20 disadvantaged area was as conducive to buying healthier food choices as in a more advantaged  
21  
22 area. One possible explanation could be that within the German population social inequality is  
23  
24 less pronounced than in other countries such as the U.S. and therefore the difference of social  
25  
26 status in the chosen urban districts was too small to be a factor in the food environment.  
27  
28

29  
30 However, for the districts observed, energy dense foods were cheaper and therefore potentially  
31  
32 more in demand in low SI districts than nutrient rich foods. Nevertheless, while prices for  
33  
34 healthy foods appear to be similar in the districts, the purchase of such foods is determined by  
35  
36 financial resources available to buyers. In particular, food inequity could be questioned since  
37  
38 people with lower purchasing power have to pay similar prices for healthy foods compared to  
39  
40 those with higher purchasing power.  
41  
42  
43  
44

45  
46 Our findings could suggest that inequalities in food intake may have little to do with the food  
47  
48 environment in Germany but rather the economics of food choice. Social inequality in Germany  
49  
50 has been linked to obesity and other chronic disease and as Drewnowski and colleagues  
51  
52 (Drewnowski et al. 2005; Drewnowski 2004) have recently pointed out, more likely factors for  
53  
54 the lower nutritional quality of diets of low-income households could be the low cost of energy-  
55  
56 dense foods. Thus, as long as energy dense foods are highly palatable and cheaper we believe it

will be difficult to change low-income household's food choices and health inequity through pricing remains.

Further research needs to be conducted not only in other geographical areas in Germany and Europe in general but also other mechanisms such as cooking skills and habits in households as well as food costs and its relationship with energy density need to be examined. Currently not enough is known if and how household and food shopping environments affect population intake of fruits and vegetables and its relationship to socioeconomic inequalities in food intake.
