#### Abstract

This paper is concerned with the study of a model case of first order HamiltonJacobi equations posed on a "junction", that is to say the union of a finite number of half-lines with a unique common point. The main results are a comparison principle, existence and stability of solutions. The two challenging difficulties are the singular geometry of the domain and the discontinuity of the Hamiltonian. As far as discontinuous Hamiltonians are concerned, these results seem to be new. They are applied to the study of some models arising in traffic flows. The techniques developed in the present article provide powerful new tools in the analysis of such traffic flow problems.

Keywords. Hamilton-Jacobi equations, discontinuous Hamiltonians, viscosity solutions, optimal control, traffic problems, junctions

Mathematical Subject Classication. 35F21, 35D40, 35Q93, 35R05, 35B51

## 1 Introduction

In this paper we are interested in Hamilton-Jacobi (HJ) equations posed on one dimensional domain containing one single singularity. This is a special case of a more general setting where HJ equations are posed in domains that are unions of submanifolds whose dimensions

[^0]are different [10]. An intermediate setting is the study of HJ equations on networks [1]. We will restrict ourselves to a very simple network: the union of a finite numbers of half-lines of the plane with a single common point. Such a domain is referred to as a junction and the common point is called the junction point. Our motivation comes from traffic flows. For this reason, it is natural to impose different dynamics on each branch of the junction. Consequently, the resulting Hamiltonian is by nature discontinuous at the junction point. Together with the singularity of the domain, this is the major technical difficulty to overcome. The analysis relies on the complete study of some distance function related to the optimal control interpretation of the equation [39, 19].

We first present the problem and the main results in details. Then we recall existing results and compare them with ours.

### 1.1 Setting of the problem

In this subsection, the analytical problem is introduced in details. We first define the junction, then the space of functions on the junction and finally the Hamilton-Jacobi equation.

The junction. Let us consider $N \geq 1$ different unit vectors $e_{i} \in \mathbb{R}^{2}$ for $i=1, \ldots, N$. We define the branches

$$
J_{i}=[0,+\infty) \cdot e_{i}, \quad J_{i}^{*}=J_{i} \backslash\{0\}, \quad i=1, \ldots, N
$$

and the junction (see Figure 1)

$$
J=\bigcup_{i=1, \ldots, N} J_{i} .
$$

The origin $x=0$ is called the junction point. For a time $T>0$, we also define

$$
J_{T}=(0, T) \times J
$$

The reader can remark that we chose to embed the junction in a two-dimensional Euclidian space. But we could also have considered an abstract junction, or we could have embedded it for instance in a higher dimensional Euclidian space. We made such a choice for the sake of clarity.

Space of functions. For a function $u: J_{T} \rightarrow \mathbb{R}$, we denote by $u^{i}$ the restriction of $u$ to $(0, T) \times J_{i}$. Then we define the natural space of functions on the junction

$$
C_{*}^{1}\left(J_{T}\right)=\left\{u \in \operatorname{Lip}_{\mathrm{loc}}\left(J_{T}\right), \quad u^{i} \in C^{1}\left((0, T) \times J_{i}\right) \quad \text { for } \quad i=1, \ldots, N\right\}
$$

where $\operatorname{Lip}_{\mathrm{loc}}\left(J_{T}\right)$ denotes the space of locally Lipschitz continuous functions defined in $J_{T}$. In particular for $u \in C_{*}^{1}\left(J_{T}\right)$ and $x=x_{i} e_{i}$ with $x_{i} \geq 0$, we define

$$
u_{t}(t, x)=\frac{\partial u^{i}}{\partial t}\left(t, x_{i} e_{i}\right) \quad \text { and } \quad u_{x}^{i}(t, x)=\frac{\partial u^{i}}{\partial x_{i}}\left(t, x_{i} e_{i}\right) .
$$

Figure 1: A junction

Then we set

$$
\begin{cases}u_{x}(t, x)=u_{x}^{i}(t, x) & \text { if } \quad x \neq 0 \\ u_{x}(t, 0)=\left(u_{x}^{j}(t, 0)\right)_{j=1, \ldots, N} & \text { if } \quad x=0\end{cases}
$$

HJ equation on the junction. We are interested in continuous functions $u:[0, T) \times$ $J \rightarrow \mathbb{R}$ which are viscosity solutions (see Definition 2.2) on $J_{T}$ of

$$
\begin{equation*}
u_{t}+H\left(x, u_{x}\right)=0 \tag{1.1}
\end{equation*}
$$

submitted to an initial condition

$$
\begin{equation*}
u(0, x)=u_{0}(x), \quad x \in J \tag{1.2}
\end{equation*}
$$

Because of the optimal control problem we have in mind (see Subsection 1.1 below), we restrict ourselves to the simplest case of discontinuous Hamiltonians; precisely, we consider

$$
H(x, p)=\left\{\begin{array}{lll}
H_{i}(p) & \text { for } \quad p \in \mathbb{R} & \text { if } x \in J_{i}^{*} \\
\max _{i=1, \ldots, N} H_{i}^{-}\left(p_{i}\right) & \text { for } \quad p=\left(p_{1}, \ldots, p_{N}\right) \in \mathbb{R}^{N} & \text { if } x=0
\end{array}\right.
$$

where $H_{i}$ are convex functions and

$$
\begin{equation*}
H_{i}^{-}\left(p_{i}\right)=\sup _{q \leq 0}\left(p_{i} q-L_{i}(q)\right) \tag{1.3}
\end{equation*}
$$

where $L_{i}=H_{i}^{*}$ is the Legendre-Fenchel transform of $H_{i}$. We recall that it is defined for $p \in \mathbb{R}$ by

$$
H_{i}^{*}(p)=\sup _{q \in \mathbb{R}}\left(p q-H_{i}(q)\right)
$$

and that

$$
\begin{equation*}
H_{i}=L_{i}^{*} . \tag{1.4}
\end{equation*}
$$

Therefore we can rewrite equation (1.1) as follows

$$
\left\{\begin{array}{ll}
u_{t}^{i}+H_{i}\left(u_{x}^{i}\right)=0 & \text { on } \quad(0, T) \times J_{i}^{*}  \tag{1.5}\\
u_{t}+\max _{i=1, \ldots, N} H_{i}^{-}\left(u_{x}^{i}\right)=0 & \text { on } \quad(0, T) \times\{0\} .
\end{array} \quad \text { for } \quad i=1, \ldots, N,\right.
$$

The optimal control framework. In this paragraph, we give an optimal control interpretation $[33,6,4]$ of the Hamilton-Jacobi equation. We define the set of admissible controls at a point $x \in J$ by

$$
A(x)=\left\{\begin{array}{lll}
\mathbb{R} e_{i_{0}} & \text { if } & x \in J_{i_{0}}^{*} \\
\bigcup_{i=1, \ldots, N} \\
\mathbb{R}^{+} e_{i} & \text { if } \quad x=0
\end{array}\right.
$$

For $(s, y),(t, x) \in[0, T] \times J$ with $s \leq t$ (the case $s=t$ being trivial and forcing $y=x$ ), we define the set of admissible trajectories from $(s, y)$ to $(t, x)$ by

$$
\mathcal{A}(s, y ; t, x)=\left\{\begin{array}{l|l}
X \in W^{1,1}\left([s, t] ; \mathbb{R}^{2}\right): & \begin{array}{ll}
X(\tau) \in J & \text { for all } \tau \in(s, t) \\
\dot{X}(\tau) \in A(X(\tau)) & \text { for a.e. } \tau \in(s, t) \\
X(s)=y & \text { and } X(t)=x
\end{array} \tag{1.6}
\end{array}\right\} .
$$

For $P=p e_{i} \in A(x)$ with $p \in \mathbb{R}$, we define the Lagrangian on the junction

$$
L(x, P)=\left\{\begin{array}{lll}
L_{i}(p) & \text { if } & x \in J_{i}^{*}  \tag{1.7}\\
L_{0}(p) & \text { if } \quad x=0
\end{array}\right.
$$

with

$$
L_{0}(p)=\min _{j=1, \ldots, N} L_{j}(p)
$$

### 1.2 Main results

We make the following assumptions:
(A0) The initial data $u_{0}$ is Lipschitz continuous.
(A1) There exists a constant $\gamma>0$, and for all $i=1, \ldots, N$, there exists $C^{2}(\mathbb{R})$ functions $L_{i}$ satisfying $L_{i}^{\prime \prime} \geq \gamma>0$, such that (1.4) and (1.3) hold.

Theorem 1.1. (Existence and uniqueness) Assume (A0)-(A1) and let $T>0$. Then there exists a unique viscosity solution $u$ of (1.1)-(1.2) on $J_{T}$ in the sense of Definition 2.2, satisfying for some constant $C_{T}>0$

$$
\left|u(t, x)-u_{0}(x)\right| \leq C_{T} \quad \text { for all } \quad(t, x) \in J_{T}
$$

Moreover the function $u$ is Lipschitz continuous with respect to $(t, x)$ on $J_{T}$.

On one hand, we will see below that the existence of a solution can be obtained with Perron's method under weaker assumptions than (A1) (see Theorem 2.6). On the other hand, we are able to get uniqueness of the solution only under assumption (A1) and this is a consequence of the following result:
Theorem 1.2. (Comparison principle) Assume (A0)-(A1). Let $T>0$ and let $u$ (resp. $v)$ be a subsolution (resp. a supersolution) of (1.1)-(1.2) on $J_{T}$ in the sense of Definition 2.2. We also assume that there exists a constant $C_{T}>0$ such that for all $(t, x) \in J_{T}$

$$
u(t, x) \geq-C_{T}(1+|x|) \quad\left(\text { resp. } \quad v(t, x) \leq C_{T}(1+|x|)\right) .
$$

Then we have $u \leq v$ on $J_{T}$.
In order to prove this strong uniqueness result, we will use in an essential way the value function associated to the optimal control problem described in Subsection 1.1: for $t \geq 0$,

$$
\begin{equation*}
u_{o c}(t, x)=\inf _{y \in J, X \in \mathcal{A}(0, y ; t, x)}\left\{u_{0}(y)+\int_{0}^{t} L(X(\tau), \dot{X}(\tau)) d \tau\right\} \tag{1.8}
\end{equation*}
$$

where $L$ is defined in (1.7) and $\mathcal{A}(0, y ; t, x)$ is defined in (1.6).
Theorem 1.3. (Optimal control representation of the solution) Assume (A0)-(A1) and let $T>0$. The unique solution given by Theorem 1.1 is $u=u_{o c}$ with $u_{o c}$ given in (1.8). Moreover, we have the following Hopf-Lax representation formula

$$
\begin{equation*}
u_{o c}(t, x)=\inf _{y \in J}\left\{u_{0}(y)+t \mathcal{D}_{0}\left(\frac{y}{t}, \frac{x}{t}\right)\right\} \tag{1.9}
\end{equation*}
$$

with

$$
\mathcal{D}_{0}(x, y)=\inf _{X \in \mathcal{A}(0, y ; 1, x)}\left\{\int_{0}^{1} L(X(\tau), \dot{X}(\tau)) d \tau\right\} .
$$

The comparison principle is obtained by combining

- a super-optimality principle for surpersolutions $v$, which implies $v \geq u_{o c}$;
- a direct comparison result with subsolutions $u$, which gives $u_{o c} \geq u$.

We finally have the following result which shed light on the role of the junction condition (see the second line of (1.5)).
Theorem 1.4. (Comparison with continuous solutions outside de junction point) Assume (A0)-(A1) and let $T>0$. Let $u \in C([0, T) \times J)$ be such that $u(0, \cdot)=u_{0}$ and for each $i \in\{1, \ldots, N\}$, the restriction $u^{i}$ of $u$ to $(0, T) \times J_{i}$ is a classical viscosity solution of

$$
u_{t}^{i}+H_{i}\left(u_{x}^{i}\right)=0 \quad \text { on } \quad(0, T) \times J_{i}^{*} .
$$

Then $u$ is a subsolution of (1.1)-(1.2) on $J_{T}$ in the sense of Definition 2.2, and $u \leq u_{o c}$.
An immediate consequence of Theorem 1.4 is the fact that the optimal control solution $u_{o c}$ is the maximal continuous function which is a viscosity solution on each open branch.

We apply in Section 6 our HJ approach to describe traffic flows on a junction. In particular, we recover the well-known junction conditions of Lebacque (see [30]) or equivalently those for the Riemann solver at the junction as in the book of Garavelo and Piccoli [24].

### 1.3 Comments

We already mentioned that the main difficulties we have to overcome in order to get our main results are on one hand the singular geometry of the domain and on the other hand the discontinuity of the Hamiltonian.

Discontinuity. There is an important literature concerning Hamilton-Jacobi equations with discontinuous coefficients; see for instance $[7,47,5,41,35,15,8,9,44,46,13,11,45$, $17,16]$. There are also many results concerning scalar conservation laws with discontinuous flux functions; see for instance $[38,3,12]$ and references therein. But there are very few results (if any) building bridges between these two kinds of results.

Networks. As it is explained in [12] for instance, the study of traffic flows on networks is an important source of problems for scalar conservation laws with discontinuous coefficients [24, 18]. The study of Hamilton-Jacobi equations on networks is more recent; the reader is referred to $[1,37]$ and references therein. To the best of our knowledge, comparison principles in such a setting were only proved for continuous Hamiltonians up to now.

The optimal control interpretation. As explained above, the comparison principle is proved by using in an essential way the optimal control interpretation of the HamiltonJacobi equation. The use of representation formulas and/or optimality principles is classical in the study of Hamilton-Jacobi equations [34, 42, 43, 25, 26]. More specifically, it is also known that a "metric" interpretation of the Hamilton-Jacobi equation is fruitful [39]. Such an interpretation plays a central role in the weak KAM theory [19].

As far as our problem is concerned, we are not able to adapt the classical viscosity solution approach to get uniqueness (doubling variables techniques). On the contrary, we get it by proving e.g. a super-optimality principle (see the discussion above) and by using representation formulas in the spirit of the works cited above.

We would like next to be a bit more precise. The technical core of the paper lies in Theorem 3.4. This result implies that the function

$$
\mathcal{D}(s, y ; t, x)=(t-s) \mathcal{D}_{0}\left(\frac{y}{t-s}, \frac{x}{t-s}\right)
$$

is semi-concave with respect to $(t, x)$ and $(s, y)$ and, if there are at least two branches $(N \geq 2)$, that $\mathcal{D}$ satisfies

$$
\left\{\begin{aligned}
\mathcal{D}_{t}+H\left(x, \mathcal{D}_{x}\right) & =0 \\
-\mathcal{D}_{s}+H\left(y,-\mathcal{D}_{y}\right) & =0
\end{aligned}\right.
$$

(in a weak sense made precise in the statement of Theorem 3.4). In the case where the Lagrangians coincide at the junction point $\left(L_{1}(0)=\ldots=L_{N}(0)\right)$, it turns out that the restriction $\mathcal{D}_{0}^{j i}(y, x)$ of $\mathcal{D}_{0}$ to $J_{j} \times J_{i}$ belong to $C^{1}\left(J_{j} \times J_{i}\right)$ and is convex. A more general case is considered in this paper: Lagrangians can differ at the junction point and in this case, the functions $\mathcal{D}_{0}^{j i}$ are not convex nor $C^{1}$ anymore for some $(i, j)$.

Viability and state constraints. We would like to make a final comment: in view of the geometric framework we chose, we see that the problem under analysis has to do with state constraints problems [40, 29, 14, 28]; indeed, the trajectories of the dynamical system are constrainted to stay on the junction. Similarly, our problem is related to the viability theory [2, 20, 21, 22, 23]. However, we did not use this approach/these techniques here.

Generalization and open problems Eventually, we briefly mention natural generalizations of our results and some important open problems. First of all, it is natural to let Hamiltonians $H_{i}$ depend on the space variable $x$. It is also natural to consider general networks by considering several junction points. We believe these generalizations can be achieved but this could be very technical. Dealing with non-convex and/or non-coercive Hamiltonians is quite challenging and some intermediate conditions should probably be imposed. For instance, the controllability of the underlying dynamical system ensures that we can work with continuous viscosity solutions.

### 1.4 Organization of the article

In Section 2, the definition of (viscosity) solutions is made precise. In Section 3, the first important properties of optimal trajectories are given. Section 4 is devoted to the proof of the main results of the paper. In particular, the comparison principle is proved by proving a super-optimality principle and by comparing subsolutions with the solution given by the optimal control interpretation of the equation. Section 5 is devoted to the proof of the technical core of the paper, namely the existence of test functions for the "distance function" associated with the optimal control interpretation.

### 1.5 Notation

Distance and coordinates in the junction. We denote by $d$ the geodesic distance defined on $J$ by

$$
d(x, y)=\left\{\begin{array}{lll}
|x-y| & \text { if } x, y \quad \text { belong to the same branch } J_{i} \text { for some } i \\
|x|+|y| & \text { if } x, y \text { do not belong to the same branch. }
\end{array}\right.
$$

For $x \in J, B(x, r)$ denotes the (open) ball centered at $x$ of radius $r$. We also consider balls $B((t, x), r)$ centered at $(t, x) \in(0,+\infty) \times J$ of radius $r>0$. For $x \in J$, let us define the index $i(x)$ of the branch where $x$ lies. Precisely we set:

$$
i(x)=\left\{\begin{array}{lll}
i_{0} & \text { if } & x \in J_{i_{0}}^{*} \\
0 & \text { if } & x=0
\end{array}\right.
$$

Up to reordering the indices, we assume that there exists an index $k_{0} \in\{1, \ldots, N\}$ such that

$$
\begin{equation*}
L_{0}(0)=L_{1}(0)=\cdots=L_{k_{0}}(0)<L_{k_{0}+1}(0) \leq \cdots \leq L_{N}(0) . \tag{1.10}
\end{equation*}
$$

We also set

$$
I_{0}=\left\{1, . ., k_{0}\right\} \quad \text { and } \quad I_{N}=\{1, \ldots, N\} .
$$

Functions defined in $\mathbf{J}^{\mathbf{2}}$. For a function $\varphi$ defined on $J \times J$, we call $\varphi^{i j}$ its restriction to $J_{i} \times J_{j}$. Then we define the space

$$
C_{*}^{1}\left(J^{2}\right)=\left\{\varphi \in C\left(J^{2}\right), \quad \varphi^{i j} \in C^{1}\left(J_{i} \times J_{j}\right) \quad \text { for all } \quad i, j \in I_{N}\right\} .
$$

We also call for $x=x_{i} e_{i}$ with $x_{i} \geq 0$ and $y=y_{j} e_{j}$ with $y_{j} \geq 0$

$$
\partial_{x}^{i} \varphi(x, y)=\frac{\partial}{\partial x_{i}} \varphi^{i j}\left(x_{i} e_{i}, y\right) \quad \text { and } \quad \partial_{y}^{j} \varphi(x, y)=\frac{\partial}{\partial y_{j}} \varphi^{i j}\left(x, y_{j} e_{j}\right)
$$

and

$$
\partial_{x} \varphi(x, y)= \begin{cases}\partial_{x}^{i} \varphi(x, y) & \text { if } \quad x \in J_{i}^{*} \\ \left(\partial_{x}^{i} \varphi(x, y)\right)_{i=1, \ldots, N} & \text { if } \quad x=0\end{cases}
$$

and similarly

$$
\partial_{y} \varphi(x, y)= \begin{cases}\partial_{y}^{j} \varphi(x, y) & \text { if } y \in J_{j}^{*} \\ \left(\partial_{y}^{j} \varphi(x, y)\right)_{j=1, \ldots, N} & \text { if } y=0\end{cases}
$$

We also set

$$
\left\{\begin{array}{lll}
x \partial_{x} \varphi(x, y)=x_{i} \partial_{x}^{i} \varphi(x, y) & \text { if } & x \in J_{i} \\
y \partial_{y} \varphi(x, y)=y_{j} \partial_{y}^{j} \varphi(x, y) & \text { if } & y \in J_{j}
\end{array}\right.
$$

## 2 Viscosity solutions

In this section, we consider a weaker assumption than (A1). We introduce the following assumption:
(A1') For each $i \in I_{N}$,

- the function $H_{i}: \mathbb{R} \rightarrow \mathbb{R}$ is continuous and

$$
\lim _{|p| \rightarrow+\infty} H_{i}(p)=+\infty
$$

- there exists $p_{0}^{i}$ such that $H_{i}$ is non-increasing on $\left(-\infty, p_{0}^{i}\right.$ ] and non-decreasing on $\left[p_{0}^{i},+\infty\right)$;

When (A1') holds true, the function $H_{i}^{-}$is defined by $H_{i}^{-}(p)=\inf _{q \leq 0} H_{i}(p+q)$. We now make the following useful remark.

Lemma 2.1. Assumption (A1) implies assumption (A1').

### 2.1 Definition of viscosity solutions

In this subsection, we give equivalent definitions of viscosity solutions for (1.1). We give a first definition where the jonction condition is satisfied in "the classical sense"; we then prove that it is equivalent to impose it in "the generalized sense".

We give the definition of viscosity solutions for (1.1) in terms of test functions by imposing the junction condition in the classical sense. We recall the definition of the upper and lower semi-continuous envelopes $u^{*}$ and $u_{*}$ of a function $u:[0, T) \times J$ :

$$
u^{*}(t, x)=\limsup _{(s, y) \rightarrow(t, x)} u(s, y) \quad \text { and } \quad u_{*}(t, x)=\liminf _{(s, y) \rightarrow(t, x)} u(s, y)
$$

Definition 2.2. (Viscosity solutions) A function $u:[0, T) \times J \rightarrow \mathbb{R}$ is a subsolution (resp. supersolution) of (1.1) on $J_{T}$ if it is upper semi-continuous (resp. lower semicontinuous) and if for any $\phi \in C_{*}^{1}\left(J_{T}\right)$ such that $u \leq \phi$ in $B(P, r)$ for some $P=(t, x) \in J_{T}$, $r>0$ and such that $u=\phi$ at $P \in J_{T}$, we have

$$
\phi_{t}(t, x)+H\left(x, \phi_{x}(t, x)\right) \leq 0 \quad(\text { resp } . \geq 0)
$$

that is to say

- if $x \in J_{i}^{*}$, then

$$
\phi_{t}(t, x)+H_{i}\left(\phi_{x}(t, x)\right) \leq 0 \quad(\text { resp } . \geq 0) ;
$$

- if $x=0$, then

$$
\begin{equation*}
\phi_{t}(t, 0)+\max _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right) \leq 0 \quad(\text { resp } . \geq 0) \tag{2.1}
\end{equation*}
$$

A function $u:[0, T) \times J \rightarrow \mathbb{R}$ is a subsolution (resp. supersolution) of (1.1)-(1.2) on $J_{T}$ if it is a subsolution (resp. supersolution) of (1.1) on $J_{T}$ and moreover satisfies $u(0, \cdot) \leq u_{0}\left(\right.$ resp. $\left.u(0, \cdot) \geq u_{0}\right)$.

A function $u:[0, T) \times J \rightarrow \mathbb{R}$ is a (viscosity) solution of (1.1) (resp. (1.1)-(1.2)) on $J_{T}$ if $u^{*}$ is a subsolution and $u_{*}$ is a supersolution of (1.1) (resp. (1.1)-(1.2)) on $J_{T}$.

Proposition 2.3. (Equivalence with relaxed junction conditions) Assume ( $A 1^{\prime}$ ). A function $u: J_{T} \rightarrow \mathbb{R}$ is a subsolution (resp. supersolution) of (1.1) on $J_{T}$ if and only if for any function $\phi \in C_{*}^{1}\left(J_{T}\right)$ such that $u \leq \phi$ in $J_{T}$ and $u=\phi$ at $(t, x) \in J_{T}$,

- if $x \in J_{i}^{*}$, then

$$
\phi_{t}(t, x)+H_{i}\left(\phi_{x}(t, x)\right) \leq 0 \quad(\text { resp } . \geq 0)
$$

- if $x=0$, then either there exists $i \in I_{N}$ such that

$$
\phi_{t}(t, 0)+H_{i}\left(\phi_{x}(t, 0)\right) \leq 0 \quad(\text { resp } . \geq 0)
$$

or (2.1) holds true.

Proof of Proposition 2.3. We classically reduce to the case where the ball $B(P, r)$ is replaced with $J_{T}$.

The "if" part is clear. Let us prove the "only if" one. We distinguish the subsolution case and the supersolution one. We start with supersolutions since it is slightly easier.
Case 1: supersolution case. We consider a test function $\phi \in C_{*}^{1}\left(J_{T}\right)$ such that $u \geq \phi$ in $J_{T}$ and $u=\phi$ at $(t, x)$. There is nothing to prove if $x \neq 0$ so we assume $x=0$. We have to prove that $\phi_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right) \geq 0$. We argue by contradiction and we assume that

$$
\begin{equation*}
\phi_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right)<0 \tag{2.2}
\end{equation*}
$$

Then it is easy to see that there exists a function $\tilde{\phi} \in C_{*}^{1}\left(J_{T}\right)$ such that $\phi \geq \tilde{\phi}$ with equality at the point $(t, 0)$ and such that

$$
\begin{equation*}
\tilde{\phi}_{x}^{i}(t, 0)=\min \left(\phi_{x}^{i}(t, 0), p_{0}^{i}\right) \quad \text { and } \quad \tilde{\phi}_{t}(t, 0)=\phi_{t}(t, 0) . \tag{2.3}
\end{equation*}
$$

Notice that

$$
\begin{equation*}
H_{i}^{-}\left(\tilde{\phi}_{x}^{i}(t, 0)\right) \leq H_{i}\left(\tilde{\phi}_{x}^{i}(t, 0)\right) \leq H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right) . \tag{2.4}
\end{equation*}
$$

The first inequality is straightforward. To check the second inequality, we have to distinguish two cases. Either we have $\tilde{\phi}_{x}^{i}(t, 0)<\phi_{x}^{i}(t, 0)$, and then $\tilde{\phi}_{x}^{i}(t, 0)=p_{0}^{i}$ and we use the fact that the minimum of $H_{i}^{-}$is $H_{i}\left(p_{0}^{i}\right)$. Or $\tilde{\phi}_{x}^{i}(t, 0)=\phi_{x}^{i}(t, 0)$ and then this common value belongs to the interval $\left(-\infty, p_{0}^{i}\right.$ ] on which we have $H_{i}=H_{i}^{-}$.

Since $u \geq \tilde{\phi}$ in $J_{T}$ and $u=\tilde{\phi}$ at $(t, 0)$, we conclude that either

$$
\tilde{\phi}_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\tilde{\phi}_{x}^{i}(t, 0)\right) \geq 0
$$

or there exists $i \in I_{N}$ such that

$$
\tilde{\phi}_{t}(t, 0)+H_{i}\left(\tilde{\phi}_{x}^{i}(t, 0)\right) \geq 0
$$

In view of (2.3) and (2.4), we obtain a contradiction with (2.2).
Case 2: subsolution case. We consider a function $\phi \in C^{1}\left(J_{T}\right)$ such that $u \leq \phi$ in $J_{T}$ and $u=\phi$ at $(t, x)$. There is nothing to prove if $x \neq 0$ and we thus assume $x=0$. We have to prove that $\phi_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right) \leq 0$. We argue by contradiction and we assume that

$$
\begin{equation*}
\phi_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right)>0 . \tag{2.5}
\end{equation*}
$$

In order to construct a test function $\tilde{\phi}$, we first consider $\bar{I}_{1} \subset I_{N}$ the set of $j$ 's such that

$$
H_{j}^{-}\left(\phi_{x}^{j}(t, 0)\right)<\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right)
$$

Since $H_{j}$ is coercive, there exists $q^{j} \geq p_{0}^{j}$ such that $H_{j}\left(q^{j}\right)=\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right)$.

We next consider a test function $\tilde{\phi} \in C_{*}^{1}\left(J_{T}\right)$ such that $\phi \leq \tilde{\phi}$ with equality at $(t, 0)$ and such that

$$
\tilde{\phi}_{x}^{i}(t, 0)=\left\{\begin{array}{ll}
\max \left(\phi_{x}^{i}(t, 0), q^{i}\right) & \text { if } i \in \bar{I}_{1},  \tag{2.6}\\
\phi_{x}^{i}(t, 0) & \text { if not, }
\end{array} \quad \text { and } \quad \tilde{\phi}_{t}(t, 0)=\phi_{t}(t, 0) .\right.
$$

Notice that for all $j \in I_{N}$,

$$
\begin{equation*}
H_{j}\left(\tilde{\phi}_{x}^{j}(t, 0)\right) \geq \sup _{i \in I_{N}} H_{i}^{-}\left(\tilde{\phi}_{x}^{i}(t, 0)\right)=\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}(t, 0)\right) \tag{2.7}
\end{equation*}
$$

where for the inequality, we have in particular used the fact that $H_{j}$ is non-decreasing on $\left[p_{0}^{j},+\infty\right)$.

Since $u \leq \tilde{\phi}$ in $J_{T}$ and $u=\tilde{\phi}$ at $(t, 0)$, we conclude that either

$$
\tilde{\phi}_{t}(t, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\tilde{\phi}_{x}^{i}(t, 0)\right) \leq 0
$$

or there exists $j \in I_{N}$ such that

$$
\tilde{\phi}_{t}(t, 0)+H_{j}\left(\tilde{\phi}_{x}^{j}(t, 0)\right) \leq 0
$$

In view of (2.6) and (2.7), we obtain a contradiction with (2.5). This ends the proof of the Proposition.

Proposition 2.4. (Continuity implies the subsolution property at the junction point) Assume (A1') and let $T>0$. Let $u: J_{T} \rightarrow \mathbb{R}$ be upper semi-continuous such that for each $i \in I_{N}$, the restriction $u^{i}$ of $u$ to $(0, T) \times J_{i}$ is a classical viscosity subsolution, i.e. satisfies

$$
u_{t}^{i}+H_{i}\left(u_{x}^{i}\right) \leq 0 \quad \text { on } \quad(0, T) \times J_{i}^{*}
$$

If moreover $u$ (as a function on $J_{T}$ ) is continuous on $(0, T) \times\{0\}$, then $u$ is a subsolution of (1.1) on $J_{T}$ in the sense of Definition 2.2.

Proof of Proposition 2.4. Let us consider a function $\phi \in C_{*}^{1}\left(J_{T}\right)$ such that $v \leq \phi$ with equality at $\left(t_{0}, 0\right)$ with $t_{0} \in(0, T)$. Up to modify $\phi$, we can always assume that the suppremum for $u-\phi$ is strict (and reached at $\left(t_{0}, 0\right)$ ). For $\eta=\left(\eta_{1}, \ldots, \eta_{N}\right) \in\left(\mathbb{R}^{+}\right)^{N}$, we set

$$
M_{\eta}=\sup _{\left(t, x=x_{j} e_{j}\right) \in J_{T}}\left(u(t, x)-\phi(t, x)-\frac{\eta_{j}}{\left|x_{j}\right|}\right) .
$$

Because $u$ is continuous at $\left(t_{0}, 0\right)$, we get for $\eta \in\left(\mathbb{R}_{*}^{+}\right)^{N}$ that

$$
\left\{\left.\begin{array}{l}
M_{\eta} \rightarrow M_{0}  \tag{2.8}\\
\left(t^{\eta}, x^{\eta}\right) \rightarrow\left(t_{0}, 0\right)
\end{array} \right\rvert\, \text { as soon as one of the component } \eta_{i_{0}} \rightarrow 0\right.
$$

where $\left(t^{\eta}, x^{\eta}\right) \in J_{T}$ is a point where the suppremum in $M_{\eta}$ is reached.

Moreover given the components $\eta_{j}>0$ for $j \in I_{N} \backslash\left\{i_{0}\right\}$, we can use (2.8) in order to find $\eta_{i_{0}}>0$ small enough to insure that $x^{\eta} \in J_{i_{0}}^{*}$. Then we have in particular the following subsolution viscosity inequality at that point $\left(t^{\eta}, x^{\eta}\right)$ :

$$
\phi_{t}+H_{i_{0}}\left(\phi_{x}-\frac{\eta_{i_{0}}}{\left|x^{\eta}\right|^{2}}\right) \leq 0 .
$$

Therefore passing to the limit $\eta_{i_{0}} \rightarrow 0$, we get

$$
\phi_{t}+H_{i_{0}}^{-}\left(\phi_{x}^{i_{0}}\right) \leq 0 \quad \text { at } \quad\left(t_{0}, 0\right) .
$$

Because this is true for any index $i_{0} \in I_{N}$, we finally get the subsolution viscosity inequality at the junction:

$$
\phi_{t}+\max _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}\right) \leq 0 \quad \text { at } \quad\left(t_{0}, 0\right) .
$$

This ends the proof of the proposition.

### 2.2 Stability results

In view of Proposition 2.3, the following stability results are classical in the viscosity solution framework. See for instance [6].

Proposition 2.5. (Stability) Assume (A1') and let $T>0$.

- Consider a family of subsolutions (resp. supersolutions) $\left(u_{\alpha}\right)_{\alpha \in A}$ of (1.1) on $J_{T}$ such that the u.s.c. (resp. l.s.c.) envelope $u$ of

$$
\sup _{\alpha \in A} u_{\alpha} \quad\left(\text { resp. } \inf _{\alpha \in A} u_{\alpha}\right)
$$

is finite everywhere. Then $u$ is a subsolution (resp. supersolution) of (1.1) on $J_{T}$.

- Consider a family of subsolutions (resp. supersolutions) $\left(u_{\varepsilon}\right)_{\varepsilon \in(0,1)}$ of (1.1) on $J_{T}$ such that the upper (resp. lower) relaxed semi-limit $u$ is finite everywhere. Then $u$ is a subsolution (resp. supersolution) of (1.1) on $J_{T}$.

### 2.3 Perron's method

In this subsection, we explain how to construct a solution of (1.1)-(1.2) by using Perron's method which is the classical way to get existence in the viscosity solution framework. In the next section, we will construct a solution by considering an associated optimal control problem.

Theorem 2.6. (Existence) Assume (A0)-(A1') and let $T>0$. Then there exists an upper semi-continuous function $u:[0, T) \times J \rightarrow \mathbb{R}$ which is a viscosity solution of (1.1)(1.2) on $J_{T}$ and satisfies

$$
\left|u(t, x)-u_{0}(x)\right| \leq C t \quad \text { for } \quad(t, x) \in[0, T) \times J
$$

Proof of Theorem 2.6. We first consider $u^{ \pm}(t, x)=u_{0}(x) \pm C t$. We claim that for $C$ large enough, $u^{+}$(resp. $u^{-}$) is a supersolution (resp. subsolution) of (1.1) on $J_{T}$. Indeed, it is enough to choose $C$ such that

$$
C \geq \max _{i \in I_{N},|p| \leq\left\|D u_{0}\right\|_{\infty}} H_{i}(p) \quad \text { and } \quad-C \leq \min _{i \in I_{N},|p| \leq\left\|D u_{0}\right\|_{\infty}} H_{i}^{-}(p)
$$

The following is quite classical. We consider the set of all subsolutions lying between $u^{-}$ and $u^{+}$,

$$
\mathcal{S}=\left\{v:[0, T) \times J \rightarrow \mathbb{R}: \quad u^{-} \leq v \leq u^{+}, \quad v \text { subsolution of }(1.1) \text { on } J_{T}\right\}
$$

we then consider the upper-semi continuous envelope $u$ of $\sup _{v \in \mathcal{S}} v$. Notice that $u=u_{0}(x)$.
Proposition 2.5 implies that $u$ is still a subsolution of (1.1) on $J_{T}$. Moreover, it is maximal. Notice also that the initial condition is satisfied: $u(0, x)=u_{*}(0, x)=u_{0}(x)$.

We next assume by contradiction that the lower semi-continuous envelope $u_{*}$ of $u$ is not a supersolution at $\left(t_{0}, 0\right)$ with $t_{0} \in(0, T)$ (otherwise the raisoning is classical outside the junction point). Using the equivalence of the definition of viscosity supersolution with relaxed junction conditions (see Proposition 2.3) we can assume that there exists a function $\phi \in C_{*}^{1}\left(J_{T}\right)$ such that $u_{*} \geq \phi$ on a neighborhood of $\left(t_{0}, 0\right)$ with equality at $\left(t_{0}, 0\right)$ and

$$
\begin{cases}\phi_{t}\left(t_{0}, 0\right)+\sup _{i \in I_{N}} H_{i}^{-}\left(\phi_{x}^{i}\left(t_{0}, 0\right)\right)<0, \\ \phi_{t}\left(t_{0}, 0\right)+H_{i}\left(\phi_{x}^{i}\left(t_{0}, 0\right)\right)<0 & \text { for all } \quad i \in I_{N}\end{cases}
$$

Our goal is to construct a bump function $Q$ to contradict the maximality of $u$. We define for $x=x_{i} e_{i}$ with $x_{i} \geq 0$ and small $\delta, \varepsilon>0$
$Q(t, x)=u_{*}\left(t_{0}, 0\right)+\left(p_{i}-\varepsilon\right) x_{i}+\lambda\left(t-t_{0}\right)+\delta-\varepsilon\left|t-t_{0}\right| \quad$ with $\quad p_{i}=\phi_{x}^{i}\left(t_{0}, 0\right), \quad \lambda=\phi_{t}\left(t_{0}, 0\right)$
Then it is straighforward to check that $Q$ is a subsolution in $B\left(\left(t_{0}, 0\right), r\right)$ for all $0<r \leq r(\varepsilon)$ with $r(\varepsilon)>0$ small enough. On the other hand, we have

$$
\phi(t, x) \geq u_{*}\left(t_{0}, 0\right)+p_{i} x_{i}+\lambda\left(t-t_{0}\right)+o\left(\left|t-t_{0}\right|+\left|x_{i}\right|\right)
$$

Therefore
$u_{*}(t, x) \geq \phi(t, x) \geq Q(t, x)-\delta+\varepsilon\left(\left|x_{i}\right|+\left|t-t_{0}\right|\right)+o\left(\left|t-t_{0}\right|+\left|x_{i}\right|\right)>Q(t, x) \quad$ on $\quad \partial B\left(\left(t_{0}, 0\right), r\right)$ for $0<\delta \leq \delta(\varepsilon, r(\varepsilon))$ small enough. Then we consider (with $r<t_{0}$ )

$$
\tilde{u}=\left\{\begin{array}{lll}
\max (u, Q) & \text { on } & B\left(\left(t_{0}, 0\right), r\right) \\
u & \text { on } & ([0, T) \times J) \backslash B\left(\left(t_{0}, 0\right), r\right)
\end{array}\right.
$$

It is straightforward to check that $\tilde{u}$ is a subsolution. It is then easy to check that we do not have $\tilde{u} \leq u$ for $\delta>0$. Thererefore $\tilde{u}$ is a subsolution which is bigger than the maximal subsolution $u$ at some point. Contradiction. This ends the proof of the Theorem.

## 3 Study of the optimal control solution

In this section, we prove a few properties related to the following "optimal control solution" for $t \geq 0$

$$
\begin{equation*}
u_{o c}(t, x)=\inf _{y \in J, X \in \mathcal{A}(0, y ; t, x)}\left\{u_{0}(y)+\int_{0}^{t} L(X(\tau), \dot{X}(\tau)) d \tau\right\} \tag{3.1}
\end{equation*}
$$

We will prove in the next Section that this is the solution of (1.1)-(1.2). Let us define the action

$$
\mathcal{E}_{s}^{t}(X):=\int_{s}^{t} L(X(\tau), \dot{X}(\tau)) d \tau
$$

### 3.1 The minimal action $\mathcal{D}$

Then it is convenient to introduce the following minimal action: for $s<t$

$$
\begin{equation*}
\mathcal{D}(s, y ; t, x)=\inf _{X \in \mathcal{A}(s, y ; t, x)} \mathcal{E}_{s}^{t}(X) \tag{3.2}
\end{equation*}
$$

and for $s=t$

$$
\mathcal{D}(t, y ; t, x)=\left\{\begin{array}{lll}
0 & \text { if } & y=x \\
+\infty & \text { if } & y \neq x
\end{array}\right.
$$

Then, by definition of $\mathcal{D}$, we can rewrite $u_{o c}(t, x)$ for $(t, x) \in[0, T) \times J$ as

$$
\begin{equation*}
u_{o c}(t, x)=\inf _{y \in J}\left\{u_{0}(y)+\mathcal{D}(0, y ; t, x)\right\} \tag{3.3}
\end{equation*}
$$

We also recall that we set

$$
\begin{equation*}
\mathcal{D}_{0}(y, x)=\mathcal{D}(0, y ; 1, x) . \tag{3.4}
\end{equation*}
$$

Then we have the following result
Lemma 3.1. (Bound from below on $\mathcal{D}$ ) Assume (A1). For all $x, y \in J$ and $s<t$, we have

$$
\begin{equation*}
\mathcal{D}(s, y ; t, x)=(t-s) \mathcal{D}_{0}\left(\frac{y}{t-s}, \frac{x}{t-s}\right) \tag{3.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathcal{D}(s, y ; t, x) \geq \frac{\gamma}{4(t-s)} d(y, x)^{2}-C_{0}(t-s) \quad \text { with } \quad C_{0}:=\max \left(0,-L_{0}(0)+\frac{\gamma_{0}^{2}}{\gamma}\right) \tag{3.6}
\end{equation*}
$$

where $\gamma$ appears in (A1), $\gamma_{0}=\max _{i \in I_{N}}\left|L_{i}^{\prime}(0)\right|$ and $L_{0}(0)$ is chosen as in (1.10).
Proof of Lemma 3.1. On the one hand, equality (3.5) follows from the fact that the Lagrangian $L$ is independent on time, and by a simple change of variable. One the other hand, we have

$$
\begin{aligned}
L_{i}(p) & \geq \frac{\gamma}{2} p^{2}+L_{i}^{\prime}(0) p+L_{i}(0) \\
& \geq \frac{\gamma}{2} p^{2}-\gamma_{0}|p|+L_{0}(0) \\
& \geq \frac{\gamma}{4} p^{2}+L_{0}(0)-\frac{\gamma_{0}^{2}}{\gamma}
\end{aligned}
$$

where we have used Young's inequality to bound $\gamma_{0}|p|$. This shows that

$$
\begin{equation*}
L_{i}(p) \geq \frac{\gamma}{4} p^{2}-C_{0} \tag{3.7}
\end{equation*}
$$

Thus we can write

$$
\begin{equation*}
\int_{s}^{t} L(X(\tau), \dot{X}(\tau)) d \tau \geq-C_{0}(t-s)+\frac{\gamma}{4} \int_{s}^{t}(\dot{X}(\tau))^{2} d \tau \tag{3.8}
\end{equation*}
$$

Then Jensen's inequality allows us to conclude to (3.6). This ends the proof of the Lemma.

Lemma 3.2. (Optimal trajectories are piecewise linear) Assume (A1). For all $x, y \in$ $J$ and $s<t$, let $X \in \mathcal{A}(s, y ; t, x)$ be an optimal trajectory, i.e. such that $\mathcal{D}(s, y ; t, x)=$ $\mathcal{E}_{s}^{t}(X)$. Then $X$ is continuous and we have two cases:

- Either it is a"junction" trajectory: there exists $\tau_{1}, \tau_{2}$ satisfying $s \leq \tau_{1} \leq \tau_{2} \leq t$ such that $X=X_{\tau_{1}, \tau_{2}}$ with

$$
X_{\tau_{1}, \tau_{2}}(\tau)=\left\{\begin{array}{lll}
-\frac{y}{\tau_{1}-s}\left(\tau-\tau_{1}\right) & \text { for } & \tau \in\left[s, \tau_{1}\right)  \tag{3.9}\\
\frac{x}{t-\tau_{2}}\left(\tau-\tau_{2}\right) & \text { for } & \tau \in\left[\tau_{1}, \tau_{2}\right] \\
\text { for } & \tau \in\left(\tau_{2}, t\right]
\end{array}\right.
$$

with $\tau_{1}=s$ if and only if $y=0$, and $\tau_{2}=t$ in and only if $x=0$. Moreover we have

$$
\mathcal{E}_{s}^{t}\left(X_{\tau_{1}, \tau_{2}}\right)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)
$$

with more generally for $s \leq \tau_{1} \leq \tau_{2} \leq t$

$$
\left\{\begin{array}{l}
e_{1}\left(\tau_{1}, y\right)= \begin{cases}\left(\tau_{1}-s\right) L_{j}\left(-\frac{y_{j}}{\tau_{1}-s}\right)-\tau_{1} L_{0}(0), & \text { for } y=y_{j} e_{j} \neq 0 \\
-s L_{0}(0), & \text { for } y=0\end{cases}  \tag{3.10}\\
e_{2}\left(\tau_{2}, x\right)= \begin{cases}\left(t-\tau_{2}\right) L_{i}\left(\frac{x_{i}}{t-\tau_{2}}\right)+\tau_{2} L_{0}(0), & \text { for } x=x_{i} e_{i} \neq 0 \\
t L_{0}(0), & \text { for } x=0\end{cases}
\end{array}\right.
$$

with the convention

$$
0 L_{k}\left(\frac{z_{j}}{0}\right)= \begin{cases}0 & \text { if } z_{j}=0 \\ +\infty & \text { if } z_{j} \in \mathbb{R} \backslash\{0\}\end{cases}
$$

- or it is a "straight line" trajectory: We have

$$
\begin{equation*}
X(\tau)=y+\frac{x-y}{t-s}(\tau-s) \quad \text { for } \quad \tau \in[s, t] \tag{3.11}
\end{equation*}
$$

and

$$
\mathcal{E}_{s}^{t}(X)=(t-s) L_{i}\left(\frac{x_{i}-y_{i}}{t-s}\right) \quad \text { with } \quad x=x_{i} e_{i}, \quad y=y_{i} e_{i} .
$$

Notice that this last case (3.11) can only occur if $y$ and $x$ belong to the same branch $J_{i}^{*}$ for some $i \in I_{N}$.

Moreover given $y, x \in J, s<t$, there is at most one optimal trajectory of type (3.9) and one optimal trajectory of type (3.11).

Proof of the Lemma 3.2. The proof proceeds in several steps.
Step 1: comparison with piecewise linear trajectories. We recall that

$$
\begin{equation*}
L_{i}(p) \geq L_{i}\left(p_{0}\right)+L_{i}^{\prime}\left(p_{0}\right)\left(p-p_{0}\right)+\frac{\gamma}{2}\left(p-p_{0}\right)^{2} \tag{3.12}
\end{equation*}
$$

Case A: $X\left(\left(t_{1}, t_{2}\right)\right) \subset J_{i}^{*}$. We assume that a curve $X$ stays in one of the branch $J_{i}^{*}$ on the time interval $\left(t_{1}, t_{2}\right)$ with $t_{1}<t_{2}$, and let us consider the curve $\tilde{X}$ with same end points $X\left(t_{1}\right)$ and $X\left(t_{2}\right)$ in $J_{i}$ but linear. Then we deduce with $p_{0} e_{i}=\dot{\tilde{X}}$ and $p e_{i}=\dot{X}(\tau)$ that

$$
\begin{equation*}
\int_{t_{1}}^{t_{2}} L(X(\tau), \dot{X}(\tau)) d \tau \geq \int_{t_{1}}^{t_{2}} L(\tilde{X}(\tau), \dot{\tilde{X}}(\tau)) d \tau+\frac{\gamma}{2} \int_{t_{1}}^{t_{2}}|\dot{X}(\tau)-\dot{\tilde{X}}(\tau)|^{2} d \tau \tag{3.13}
\end{equation*}
$$

Case B: $X\left(\left[t_{1}, t_{2}\right]\right) \subset J_{i}$ with $X\left(t_{1}\right)=X\left(t_{2}\right)=0$. In that case, let us set $\tilde{X}(\tau)=0$ for $\tau \in\left[t_{1}, t_{2}\right]$. Using (3.12) with $p_{0}=0$ and the definition of $L_{0}$ as a minimum of the $L_{j}$ 's (see (1.10)), we get that

$$
L_{i}(p) \geq L_{0}(0)+L_{i}^{\prime}(0) p+\frac{\gamma}{2} p^{2}
$$

from what we deduce that (3.13) still holds true.
Case C: the general case. By assumption, we have $X \in \mathcal{A}(s, y ; t, x) \subset C([s, t])$. We then distinguish two cases. Either $0 \notin X([s, t])$, and then we define $\tilde{X}$ as in (3.11). Or $0 \in$ $X([s, t])$, and then we call $\left[\tau_{1}, \tau_{2}\right] \subset[s, t]$ the largest interval such that $X\left(\tau_{1}\right)=0=X\left(\tau_{2}\right)$, and define $\tilde{X}$ as in (3.9). Using again the continuity of $X$, we can find a decomposition of $\left[\tau_{1}, \tau_{2}\right]$ as a disjoint union of intervals $\mathcal{I}_{k}$ (with an at most countable union)

$$
\left[\tau_{1}, \tau_{2}\right]=\bigcup_{k} \mathcal{I}_{k}
$$

such that for each $k$

$$
\left\{\begin{array}{l}
X\left(\mathcal{I}_{k}\right) \subset J_{i_{k}} \quad \text { for some } \quad i_{k} \in I_{N} \\
X=0 \quad \text { on } \quad \partial \mathcal{I}_{i_{k}}
\end{array}\right.
$$

Using Case A or Case B on each segment $\overline{\mathcal{I}}_{k}$, we deduce that

$$
\mathcal{E}_{s}^{t}(X) \geq \mathcal{E}_{s}^{t}(\tilde{X})+\frac{\gamma}{2} \int_{s}^{t}|\dot{X}(\tau)-\dot{\tilde{X}}(\tau)|^{2} d \tau
$$

Step 2: minimizing among piecewise linear curves. This shows that if $X^{k}$ is a minimizing sequence, then we can replace it by a piecewise linear curve $\tilde{X}^{k}$ of one of the two types (3.9) or (3.11), such that

$$
\mathcal{E}_{s}^{t}\left(\tilde{X}^{k}\right) \leq \mathcal{E}_{s}^{t}\left(X^{k}\right)
$$

where the inequality is strict if $X^{k} \not \equiv \tilde{X}^{k}$. Notice also that from (3.8), the sequence $\left(\tilde{X}^{k}\right)_{k}$ is bounded in $H^{1}\left((s, t) ; \mathbb{R}^{2}\right)$. This implies that we can easily pass to the limit and proves the existence of a minimizer $X \in \mathcal{A}(s, y ; t, x)$ of type (3.9) or (3.11), i.e. the existence of an optimal trajectory.

Step 3: minimizers are piecewise linear. The same argument as the one of Step 1 applies to minimizers and show that they have to be piecewise linear, and then of one of the two types (3.9) or (3.11). The uniqueness of the optimal trajectory of type (3.9) follows from the strict convexity of the functions $e_{1}$ and $e_{2}$ respectively in $\tau_{1}$ and $\tau_{2}$. This ends the proof of the Lemma.

Lemma 3.3. (Lower semi-continuity of $\mathcal{D}$ ) Assume (A1). Then

- the map $(s, y ; t, x) \mapsto \mathcal{D}(s, y ; t, x)$ defined in (3.2) for $s \leq t$, is lower semi-continuous;
- $\mathcal{D}(s, y ; t, x)$ is finite for $s<t$;
- $\mathcal{D}(s, x ; t, x) \rightarrow 0$ as $s \rightarrow t$ with $s<t$ uniformly in $(t, x) \in \mathbb{R} \times J$.

Proof of the Lemma 3.3. We first write

$$
\mathcal{D}=\min \left(\mathcal{D}^{a}, \mathcal{D}^{b}\right)
$$

with $\mathcal{D}^{a}, \mathcal{D}^{b}$ are two lower semi-continuous functions defined as follows

$$
\begin{equation*}
\mathcal{D}^{a}(s, y ; t, x)=\inf _{0 \leq \tau_{1} \leq \tau_{2} \leq 1}\left\{e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)\right\} \tag{3.14}
\end{equation*}
$$

where $e_{1}$ and $e_{2}$ are two lower semi-continuous functions defined in (3.10), and

$$
\mathcal{D}^{b}(s, y ; t, x)= \begin{cases}(t-s) L_{i}\left(\frac{x_{i}-y_{i}}{t-s}\right) & \text { if }(y, x) \in J_{i}^{2} \backslash\{0\}^{2}  \tag{3.15}\\ (t-s) L_{0}(0) & \text { if } y=0=x \\ +\infty & \text { otherwise }\end{cases}
$$

Moreover $\mathcal{D}(s, y ; t, x)$ and $\mathcal{D}^{a}(s, y ; t, x)$ are finite for $s<t$.
Given $A>0$, we consider the function defined for $(\tau, y) \in(0, A] \times J$ by

$$
g(\tau, y)=\left\{\begin{array}{lll}
\tau L_{i}\left(-\frac{y_{i}}{\tau}\right) & \text { if } & y=y_{i} e_{i} \neq 0 \\
\tau L_{0}(0) & \text { if } & y=0
\end{array}\right.
$$

and for $\tau=0$ by

$$
g(0, y)= \begin{cases}+\infty & \text { if } \quad y \neq 0 \\ 0 & \text { if } \quad y=0\end{cases}
$$

We only have to check the lower semi-continuity at points $(\tau, 0)$ with $\tau \in(0, A]$ and $(0, y)$ for $y \in J$, because it is clear for the other values of $(\tau, y)$, because of the continuity of the $L_{i}$ 's.

Case 1: $(\tau, 0)$ with $\tau \in(0, A]$. The lower semi-continuity of $g$ at points $(\tau, 0)$ for $\tau>0$, follows again from the continuity of the $L_{i}$ 's and the fact that $L_{0}(0) \leq L_{i}(0)$.
CASE 2: $(0, y)$ FOR $y \in J$. The lower semi-continuity of $g$ at points $(0, y)$ follows from the inequality for $\tau>0$ (consequence of (3.7)):

$$
g(\tau, y) \geq \frac{\gamma}{4} \frac{|y|^{2}}{\tau}-C_{0} \tau
$$

This implies that $g$ is lower semi-continuous on $[0, A] \times J$. We deduce that the map $\left(s, \tau_{1}, y\right) \mapsto e_{1}\left(\tau_{1}, y\right)$ is lower semi-continuous (see the definition of $e_{1}$ in Lemma 3.2). Proceeding similarly for $e_{2}$, we conclude that the function

$$
G\left(\tau_{1}, \tau_{2} ; s, y ; t, x\right)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)
$$

is lower semi-continuous for $y, x \in J, s \leq t$ and $0 \leq \tau_{1} \leq \tau_{2} \leq 1$. Therefore the function

$$
\mathcal{D}^{a}(s, y ; t, x)=\inf _{0 \leq \tau_{1} \leq \tau_{2} \leq 1} G\left(\tau_{1}, \tau_{2} ; s, y ; t, x\right)
$$

is also lower semi-continuous. On the other hand $\mathcal{D}^{b}$ is also lower semi-continuous. From Lemma 3.2, we deduce that

$$
\mathcal{D}=\min \left(\mathcal{D}^{a}, \mathcal{D}^{b}\right)
$$

which is also a lower semi-continuous function. Moreover $G\left(s, y ; t, x ; \tau_{1}, \tau_{2}\right)<+\infty$ for $s<\tau_{1}<\tau_{2}<t$ and then $\mathcal{D}(s, y ; t, x)<+\infty$ for $s<t$. From (3.6), we deduce that $\mathcal{D}(s, y ; t, x)$ is finite for $s<t$.

To prove that $\mathcal{D} \rightarrow 0$ as $s \rightarrow t, s<t$, we simply write for $x \in J_{i}$ :

$$
\mathcal{D}(s, x ; t, x) \leq \mathcal{D}^{b}(s, x ; t, x)=(t-s) L_{i}(0) \rightarrow 0 \quad \text { as } \quad s \rightarrow t
$$

On the other hand (3.6) implies $\mathcal{D}(s, x ; t, x) \geq-C_{0}(t-s)$. This ends the proof of the lemma.

### 3.2 The key property of $\mathcal{D}$

The following result can be considered as the core of our analysis; it will be proved in the Section 5.

Theorem 3.4. (Key inequalities for $\mathcal{D}$ ) Consider $\left(s_{0}, y_{0}\right)$ and $\left(t_{0}, x_{0}\right) \in(0, T) \times J$ with $s_{0}<t_{0}$. Then there exist two functions $\phi, \psi \in C_{*}^{1}\left(J_{T}\right)$ and $r>0$ such that

- $\phi \geq \mathcal{D}\left(s_{0}, y_{0} ; \cdot, \cdot\right)$ on a ball $B\left(P_{0}, r\right)$ with equality at $P_{0}=\left(t_{0}, x_{0}\right)$ and

$$
\begin{equation*}
\phi_{t}+H\left(x_{0}, \phi_{x}\right) \geq 0 \quad \text { at } \quad\left(t_{0}, x_{0}\right) . \tag{3.16}
\end{equation*}
$$

- $\psi \geq \mathcal{D}\left(\cdot, \cdot ; t_{0}, x_{0}\right)$ on a ball $B\left(Q_{0}, r\right)$ with equality at $Q_{0}=\left(s_{0}, y_{0}\right)$ and

$$
\left\{\begin{array}{lll}
-\psi_{s}+H\left(y_{0},-\psi_{y}\right) \leq 0 \quad \text { at } \quad\left(s_{0}, y_{0}\right) & \text { if } \quad N \geq 2  \tag{3.17}\\
-\psi_{s}+H_{1}\left(-\psi_{y}\right) \leq 0 \quad \text { at } \quad\left(s_{0}, y_{0}\right) & \text { if } \quad N=1
\end{array}\right.
$$

Moreover, for all $R>0$, there exists a constant $C_{R}>0$ such that we have

$$
\begin{equation*}
d\left(y_{0}, x_{0}\right) \leq R \quad \Longrightarrow \quad\left|\phi_{x}\left(t_{0}, x_{0}\right)\right|+\left|\psi_{y}\left(s_{0}, y_{0}\right)\right| \leq C_{R} \tag{3.18}
\end{equation*}
$$

Remark 3.5. As we shall see when proving this result, we can even require equalities instead of inequalities in (3.16) and (3.17).

### 3.3 The optimal control represention of the solution

Lemma 3.6. (Properties of $u_{o c}$ ) Assume (A0)-(A1). Then the function $u_{o c}$ defined in (3.1) satisfies

$$
\left|u_{o c}(t, x)-u_{0}(x)\right| \leq C t
$$

Proof of the Lemma 3.6. We first get a bound from below. Using (3.6), we deduce (denoting by $L_{u_{0}}$ the Lipschitz constant for $u_{0}$ ):

$$
\begin{aligned}
u_{0}(y)+\mathcal{D}(s, y ; t, x) & \geq u_{0}(x)+\frac{\gamma}{4 t}(d(y, x))^{2}-C_{0} t-L_{u_{0}} d(y, x) \\
& \geq u_{0}(x)-C_{2} t
\end{aligned}
$$

with

$$
-C_{2}=\inf _{a \in[0,+\infty)}\left\{\frac{\gamma}{4} a^{2}-C_{0}-L_{u_{0}} a\right\}>-\infty
$$

This implies that

$$
u_{o c}(x) \geq u_{0}(x)-C_{2} t .
$$

We next get a bound from above. We have

$$
u_{o c}(x) \leq u_{0}(x)+\mathcal{D}(0, x ; t, x) \leq u_{0}(x)+M t
$$

with

$$
M=\sup _{i \in I_{N}} L_{i}(0)
$$

This ends the proof of the lemma.
Remark 3.7. (Dynamic Programming Principle) Under assumptions (A0)-(A1), it is possible (and easy) to prove the following Dynamic Programming Principle: for all $x \in J$ and $s \in[0, t]$,

$$
u_{o c}(t, x)=\inf _{y \in J}\left\{u_{o c}(s, y)+\mathcal{D}(s, y ; t, x)\right\}
$$

Notice that a super-optimality principle will be proved in Proposition 4.1.

## 4 Proofs of the main results

In this section, we investigate the uniqueness of the solution of (1.1)-(1.2). In particular, we will show that the solution constructed by Perron's method coincide with the function $u_{o c}$ coming from the associated optimal control problem.

### 4.1 Supersolutions and super-optimality

In this subsection, we will show that a supersolution satisfies a super-optimality principle. For the sake of clarity, we first give a formal argument to understand this claim. We consider the auxiliary function, for $s \leq t$,

$$
\begin{equation*}
U_{t, x}(s)=\inf _{y \in J}\{u(s, y)+\mathcal{D}(s, y ; t, x)\} \tag{4.1}
\end{equation*}
$$

and we are going to explain formally that it is non-decreasing with respect to $s$ as soon as $u$ is a supersolution of (1.1). We call this property a super-optimality principle. Notice that this is strongly related to the fact that the quantity $U_{t, x}(s)$ is constant in $s$ if $u$ is equal to the optimal control solution $u_{o c}$.

Assume that the infimum defining $U$ is attained for some $\bar{y} \in J$. Then we write

$$
\begin{aligned}
U_{t, x}^{\prime}(s) & =\partial_{s} u(s, \bar{y})+\partial_{s} \mathcal{D}(s, \bar{y} ; t, x) \\
\partial_{x} u(s, \bar{y}) & =-\partial_{y} \mathcal{D}(s, \bar{y} ; t, x) .
\end{aligned}
$$

Moreover assuming $\mathcal{D}$ to be smooth (which is not the case), we formally get from (3.17) the fact that $\partial_{s} \mathcal{D}(s, \bar{y} ; t, x) \geq H\left(\bar{y},-\partial_{y} \mathcal{D}(\bar{s}, \bar{y} ; t, x)\right)$ (at least in the case $\left.N \geq 2\right)$. Hence

$$
U_{t, x}^{\prime}(s) \geq \partial_{s} u(s, \bar{y})+H\left(\bar{y}, \partial_{x} u(s, \bar{y})\right) \geq 0 .
$$

We thus conclude that $U_{t, x}$ is non-decreasing if $u$ is a supersolution of (1.1). We now give a precise statement and a rigourous proof.

Proposition 4.1. (Super-optimality of supersolutions) Assume (A1). Let $u:[0, T) \times$ $J \rightarrow \mathbb{R}$ be a supersolution of (1.1) on $J_{T}$ such that there exists $\sigma>0$ such that for all $(t, x) \in J_{T}$,

$$
\begin{equation*}
u(t, x) \geq-\sigma(1+d(x, 0)) \tag{4.2}
\end{equation*}
$$

Then for all $(t, x) \in J_{T}$ and $s \in(0, t]$,

$$
\begin{equation*}
u(t, x) \geq \inf _{y \in J}\{u(s, y)+\mathcal{D}(s, y ; t, x)\} \tag{4.3}
\end{equation*}
$$

Assume moreover (A0) and that $u$ is a supersolution of (1.1)-(1.2) on $J_{T}$. Then we have $u \geq u_{o c}$ on $[0, T) \times J$.

Proof of Proposition 4.1. The proof proceeds in several steps.
Step 1: preliminary. Notice first that from (3.6), we get

$$
u(s, y)+\mathcal{D}(s, y ; t, x) \geq \frac{\gamma}{4(t-s)} d(y, x)^{2}-C_{0}(t-s)-\sigma(1+|y|)
$$

Using the lower semi-continuity of $\mathcal{D}$ (see Lemma 3.3), we see that the infimum in $y$ of this function is then reached for bounded $y$. Moreover by lower semi-continuity of the map $(s, y ; t, x) \mapsto u(s, y)+\mathcal{D}(s, y ; t, x)$, we deduce in particular that the map $(s ; t, x) \mapsto U_{t, x}(s)$ (and then also $s \mapsto U_{t, x}(s)$ ) is lower semicontinuous.
Step 2: the map $s \mapsto U_{t, x}(s)$ is non-decreasing. We are going to prove that for $s \in(0, t), U_{t, x}^{\prime}(s) \geq 0$ in the viscosity sense. We consider a test function $\varphi$ touching $U_{t, x}$ from below at $\bar{s} \in(0, t)$. There exists $\bar{y}$ such that

$$
U_{t, x}(\bar{s})=u(\bar{s}, \bar{y})+\mathcal{D}(\bar{s}, \bar{y} ; t, x) .
$$

We deduce from the definition of $U_{t, x}$ that

$$
\varphi(s)-\mathcal{D}(s, y ; t, x)-[\varphi(\bar{s})-\mathcal{D}(\bar{s}, \bar{y} ; t, x)] \leq u(s, y)-u(\bar{s}, \bar{y}) .
$$

By Theorem 3.4, there exists a test function $\psi$ such that $\psi \geq \mathcal{D}(\cdot, \cdot ; t, x)$ on a ball $B(\bar{Q}, r)$ with equality at $\bar{Q}=(\bar{s}, \bar{y})$. Hence, we can rewrite the previous inequality by replacing $\mathcal{D}$ with $\psi$. We then obtain that $(s, y) \mapsto \varphi(s)-\psi(s, y)$ is a test function touching $u$ at $(\bar{s}, \bar{y})$ from below. Since $u$ is a super-solution of (1.1), we have in the cases $N \geq 2$ or $N=1$ and $\bar{y} \neq 0$

$$
\varphi^{\prime}(\bar{s}) \geq \psi_{s}(\bar{s}, \bar{y})-H\left(\bar{y},-\partial_{y} \psi(\bar{s}, \bar{y})\right) \geq 0
$$

and in the case $N=1$ and $\bar{y}=0$

$$
\varphi^{\prime}(\bar{s}) \geq \psi_{s}(\bar{s}, \bar{y})-H_{1}^{-}\left(-\partial_{y} \psi(\bar{s}, \bar{y})\right) \geq \psi_{s}(\bar{s}, \bar{y})-H_{1}\left(-\partial_{y} \psi(\bar{s}, \bar{y})\right) \geq 0
$$

where we used the properties of the function $\psi$ given by Theorem 3.4.
Step 3: conclusion. Let us define for $(t, x) \in J_{T}$ the following kind of lower semicontinuous envelope (for the past in time)

$$
\underline{u}(t, x)=\liminf _{\left\{\left(t_{n}, x_{n}\right) \rightarrow(t, x), \quad t_{n}<t\right\}} u\left(t_{n}, x_{n}\right) .
$$

Let us notice that we have

$$
\begin{equation*}
\underline{u}_{*}=u_{*}=u \quad \text { on } \quad J_{T} . \tag{4.4}
\end{equation*}
$$

Given a point $(t, x) \in J_{T}$, let us consider a sequence such that

$$
\underline{u}(t, x)=\lim _{n \rightarrow+\infty} u\left(t_{n}, x_{n}\right) .
$$

Then we have for any $s<t_{n}<t$

$$
U_{t, x_{n}}(s) \leq U_{t, x_{n}}\left(t_{n}\right) \leq u\left(t_{n}, x_{n}\right)+\mathcal{D}\left(t_{n}, x_{n}, t, x_{n}\right) \rightarrow \underline{u}(t, x)
$$

where we have used the third item of Lemma 3.3. Therefore from the lower semicontinuity of $U$, we get

$$
U_{t, x}(s) \leq \underline{u}(t, x)
$$

Again from the lower semi-continuity of the map $(t, x) \mapsto U_{t, x}(s)$, we get passing to the lower semi-continuous envelopes in $(t, x)$ :

$$
U_{t, x}(s) \leq \underline{u}_{*}(t, x)=u(t, x)
$$

where we have used (4.4). This shows (4.3) for $0<s<t$. This is still true for $s=t$ by definition of $\mathcal{D}$. The proof is now complete.

### 4.2 Comparison with subsolutions

Proposition 4.2. (Comparison with subsolutions) Let $u: J_{T} \rightarrow \mathbb{R}$ be a subsolution of (1.1)-(1.2) on $J_{T}$, such that there exists $\sigma>0$ such that for all $(t, x) \in J_{T}$,

$$
\begin{equation*}
u(t, x) \leq \sigma(1+d(x, 0)) \tag{4.5}
\end{equation*}
$$

Then we have $u \leq u_{o c}$ on $J_{T}$.
In order to prove Proposition 4.2, we will need the following result that we first prove:
Lemma 4.3. (Bound from above on subsolutions) Assume (A0)-(A1). Let $u:[0, T) \times$ $J \rightarrow \mathbb{R}$ be a subsolution of (1.1)-(1.2) on $J_{T}$, satisfying (4.5). Then there exists a constant $C>0$ such that

$$
\begin{equation*}
u(t, x) \leq u_{0}(x)+C t \quad \text { for all } \quad(t, x) \in J_{T} . \tag{4.6}
\end{equation*}
$$

Proof of Lemma 4.3. Using the Lipschitz regularity of $u_{0}$, we can easily consider a smooth approximation $u_{0}^{\eta}$ of $u_{0}$ such that $u_{0}^{\eta} \geq u_{0}$ and $\left|u_{0}^{\eta}-u_{0}\right|_{L^{\infty}(J)} \rightarrow 0$ as $\eta \rightarrow 0$. Then consider the following supremum for $\eta, \alpha>0$

$$
N_{\eta, \alpha}=\sup _{(t, x) \in[0, T) \times J}\left\{u(t, x)-u_{0}^{\eta}(x)-C t-\alpha d(x, 0)^{2}-\frac{\eta}{T-t}\right\} .
$$

We claim that $N_{\eta, \alpha} \leq 0$ for some $C$ large enough independent on $\eta, \alpha>0$ small enough. The lemma will be obtained by letting $\alpha$ and $\eta$ go to 0 . We argue by contradiction and assume that $N_{\eta, \alpha}>0$. Thanks to (4.5), the supremum $N_{\eta, \alpha}$ is attained for some $(t, x) \in[0, T) \times J$. If $t=0$, we have $N_{\eta, \alpha} \leq 0$. Therefore $t>0$ and we can use the fact that $u$ is a subsolution to obtain for $x=x_{i} e_{i}$

$$
\frac{\eta}{T^{2}}+C-\max _{j \in I_{N}} L_{j}(0) \leq \frac{\eta}{T^{2}}+C+H\left(x, \partial_{x} u_{0}^{\eta}(x)+2 \alpha x_{i}\right) \leq 0
$$

where we have used assumption (A1) to estimate $H$ from below. Notice that we have also made use of a slight abuse of notation in the case $x=0$. Choosing $C=\max _{j \in I_{N}}\left|L_{j}(0)\right|$ allows us to conclude to a contradiction. This ends the proof of Lemma 4.3.

We now turn to the proof of Proposition 4.2.
Proof of Proposition 4.2. The proof proceeds in several steps.
Step 1: preliminaries. Let us consider

$$
M=\sup _{(t, x) \in[0, T) \times J}\left\{u(t, x)-u_{o c}(t, x)\right\} .
$$

From Lemmas 3.6 and 4.3, we deduce that we have

$$
M \leq 2 C T<+\infty
$$

We want to prove that $M \leq 0$.
To this end, we perform the usual corrections considering the following supremum for $\eta, \alpha>0$

$$
M_{\eta, \alpha}=\sup _{(t, x) \in[0, T) \times J}\left\{u(t, x)-u_{o c}(t, x)-\alpha d(x, 0)^{2}-\frac{\eta}{T-t}\right\} .
$$

As it is proved classically, we also have that $M_{\eta, \alpha} \rightarrow M_{\eta, 0}$ as $\alpha \rightarrow 0$ where

$$
M_{\eta, 0}=\sup _{(t, x) \in[0, T) \times J}\left\{u(t, x)-u_{o c}(t, x)-\frac{\eta}{T-t}\right\} .
$$

We argue by contradiction by assuming that $M>0$ and then $M_{\eta, 0} \geq M / 2>0$ for $\eta>0$ small enough and fixed for the rest of the proof.

Step 2: reduction to $\overline{\mathbf{t}}>\mathbf{0}$. Notice that the supremum $M_{\eta, \alpha}$ is achieved for points $(\bar{t}, \bar{x}) \in[0, T) \times J$. Using again Lemmas 3.6 and 4.3 , we also deduce that

$$
M / 2<M_{\eta, 0} \leq M_{\eta, \alpha}+o_{\alpha}(1) \leq 2 C \bar{t}
$$

and hence $\bar{t} \geq \frac{M}{4 C}>0$ for $\alpha$ small enough.
Step 3: a priori bounds. Using the argument of Step 1 of the proof of Proposition 4.1, we see that there exists $y \in J$ such that

$$
u_{o c}(\bar{t}, \bar{x})=u_{0}(\bar{y})+\mathcal{D}(0, \bar{y} ; \bar{t}, \bar{x}) .
$$

Therefore we can rewrite $M_{\eta, \alpha}$ as

$$
M_{\eta, \alpha}=\sup _{0 \leq t<T, x, y \in J}\left\{u(t, x)-u_{0}(y)-\mathcal{D}(0, y ; t, x)-\alpha d(x, 0)^{2}-\frac{\eta}{T-t}\right\} .
$$

and the supremum is achieved for $(\bar{t}, \bar{x}, \bar{y}) \in(0, T) \times J^{2}$. Notice that this supremum looks like the classical one for proving the comparison principle for viscosity solutions, with the usual penalization term $(y-x)^{2} / \varepsilon$ replaced here by the function $\mathcal{D}(0, y ; t, x)$.

In view of the bound (3.6) from below on $\mathcal{D}$ and (4.6), we derive from $M_{\eta, \alpha}>0$ that

$$
\frac{\eta}{T-\bar{t}}+\alpha d(\bar{x}, 0)^{2}+\frac{\gamma}{4 \bar{t}} d(\bar{y}, \bar{x})^{2} \leq C_{0} \bar{t}+C \bar{t}+L_{u_{0}} d(\bar{y}, \bar{x})
$$

where $L_{u_{0}}$ denotes the Lipschitz constant of $u_{0}$. We conclude that there exists $C_{T}$ such that

$$
\begin{equation*}
\alpha d(\bar{x}, 0)^{2} \leq C_{T} \quad \text { and } \quad d(\bar{y}, \bar{x}) \leq C_{T} \tag{4.7}
\end{equation*}
$$

where $C_{T}$ depends on $T, C_{0}, C, L_{u_{0}}$ and $\gamma$.
Step 4: getting the viscosity inequality. Since $\bar{t}>0$, we have in particular that

$$
\begin{aligned}
& u(t, x)-\left(\mathcal{D}(0, \bar{y} ; t, x)+\alpha d(x, 0)^{2}+\frac{\eta}{T-t}\right) \\
& \quad \leq u(\bar{t}, \bar{x})-\left(\mathcal{D}(0, \bar{y} ; \bar{t}, \bar{x})+\alpha d(\bar{x}, 0)^{2}+\frac{\eta}{T-\bar{t}}\right) .
\end{aligned}
$$

By Theorem 3.4, there exists a test function $\phi$ such that $\phi \geq \mathcal{D}(0, \bar{y} ; \cdot, \cdot)$ on a ball $B(\bar{P}, r)$ with equality at $\bar{P}=(\bar{t}, \bar{x})$. Hence, we can rewrite the previous inequality by replacing $\mathcal{D}$ with $\phi$. We then obtain that $(t, x) \mapsto \phi(t, x)+\alpha d(x, 0)^{2}+\frac{\eta}{T-t}$ touches $u$ from above at $(\bar{t}, \bar{x})$ with $\bar{t}>0$. We use next that $u$ is a subsolution of (1.1) and get for $\bar{x}=\bar{x}_{i} e_{i}$

$$
\frac{\eta}{T^{2}}+\phi_{t}(\bar{t}, \bar{x})+H\left(\bar{x}, \phi_{x}(\bar{t}, \bar{x})+2 \alpha \bar{x}_{i}\right) \leq 0
$$

where we have made use of a slight abuse of notation in the case $\bar{x}=0$. On the other hand, we have

$$
\phi_{t}(\bar{t}, \bar{x})+H\left(\bar{x}, \phi_{x}(\bar{t}, \bar{x})\right) \geq 0
$$

therefore

$$
\frac{\eta}{T^{2}}+H\left(\bar{x}, \phi_{x}(\bar{t}, \bar{x})+2 \alpha \bar{x}_{i}\right)-H\left(\bar{x}, \phi_{x}(\bar{t}, \bar{x})\right) \leq 0
$$

On the one hand, from (4.7), we have $0 \leq \alpha x_{i} \leq \sqrt{\alpha C_{T}}$. On the other hand, we can use (4.7) and (3.18) in order to conclude that

$$
\left|\phi_{x}(\bar{t}, \bar{x})\right| \leq \bar{C}
$$

for some constant $\bar{C}$ which does not depend on $\alpha$. We can now use the fact that the Hamiltonians are locally Lipschitz continuous in order to get the desired contradiction for $\alpha$ small enough. This ends the proof of the Proposition.

### 4.3 Proof of the main results

In this subsection, we prove the main results announced in the introduction.
Proof of Theorem 1.2. We simply apply Propositions 4.1 and 4.2 and get $u \leq u_{o c} \leq v$ which implies the result.

We now turn to the proof of Theorem 1.1.
Proof of Theorem 1.1. The uniqueness of the solution follows from Theorem 1.2. The existence were obtained in Theorem 2.6. We should next prove that it is Lipschitz continuous.

Lemma 4.4. Assume (A0)-(A1). Let $u$ be the solution of (1.1)-(1.2) on $J_{T}$ given by Theorem 2.6. Then $u$ is Lipschitz continuous with respect to $(t, x)$ on $J_{T}$.

The proof of Theorem 1.1 is now complete.
Proof of Lemma 4.4. We first recall (see Lemma 2.1) that (A1) implies (A1'). We know that the solution $u=u^{*}$ given by Theorem 2.6 satisfies for some constant $C>0$ and all $(t, x) \in J_{T}$,

$$
\left|u(t, x)-u_{0}(x)\right| \leq C t
$$

From the comparison principle (Theorem 1.2), we deduce that $u=u^{*} \leq u_{*}$ and then the solution $u=u^{*}=u_{*}$ is continuous.

For $h_{0}>0$ small (with $h_{0}<T$ ), we now consider $h \in\left(0, h_{0}\right)$ and

$$
v(t, x)=u(t+h, x)-\sup _{x \in J}\left(u(h, x)-u_{0}(x)\right) .
$$

This new function satisfies in particular $v(0, x) \leq u_{0}(x)$. Therefore $v$ is a subsolution of (1.1)-(1.2) on $J_{T-h_{0}}$. We thus conclude from the comparison principle that $v(t, x) \leq u(t, x)$, which implies

$$
u(t+h, x) \leq u(t, x)+C h \quad \text { for all } \quad(t, x) \in J_{T-h_{0}}
$$

Arguing similarly, we can prove that $u(t+h, x) \geq u(t, x)-C h$. Because $h_{0}$ can be chosen arbitrarily small, we conclude that $u$ is Lipschitz continuous with respect to time on the whole $J_{T}$.

Since $u$ is a viscosity solution of (1.1), it satisfies in particular (in the viscosity sense) for each $i \in I_{N}$ :

$$
H_{i}\left(u_{x}\right) \leq C \quad \text { on } \quad(0, T) \times J_{i}^{*} .
$$

This implies that there exists a constant $\tilde{C}$ such that (in the viscosity sense)

$$
\left|u_{x}\right| \leq \tilde{C} \quad \text { on } \quad(0, T) \times J^{*} .
$$

It is then classical that this implies that $u$ is Lipschitz continuous with respect to space (see for instance the equivalence between viscosity solutions and solutions in the sense of distributions [27]). This ends the proof of the lemma.

Proof of Theorem 1.3. The fact that the solution is equal to $u_{o c}$ follows from the comparison principle. The representation formula (1.9) follows from (3.3) and (3.5).

Proof of Theorem 1.4. The fact that $u$ is a subsolution follows from Proposition 2.4. The inequality $u \leq u_{o c}$ then follows from the comparison principle.

## 5 Study of the minimal action $\mathcal{D}_{0}$

In view of Theorem 1.3 and Lemma 3.1, the minimal action $\mathcal{D}$ defined by (3.2) turns out to be a fundamental object in our analysis. This section is devoted to the proof of Theorem 3.4. In view of (3.5), it is thus sufficient to prove the following one

Theorem 5.1. (Key equalities for $\mathcal{D}_{\mathbf{0}}$ ) Let us assume (A1). Then for all $y, x \in J$, the $\mathcal{D}_{0}(y, x)$ is finite. It is continuous in $J^{2}$ and for all $y, x \in J$, there exists a function $\varphi_{0} \in C_{*}^{1}\left(J^{2}\right)$ such that $\varphi_{0} \geq \mathcal{D}_{0}$ on $J^{2}, \varphi_{0}(y, x)=\mathcal{D}_{0}(y, x)$ and we have

$$
\begin{array}{lcl}
\text { if } x \neq 0: & \left(\varphi_{0}-x \partial_{x} \varphi_{0}-y \partial_{y} \varphi_{0}\right)(y, x)+H\left(x, \partial_{x} \varphi_{0}(y, x)\right) & =0 \\
\text { if } x=0: & \left(\varphi_{0}-x \partial_{x} \varphi_{0}-y \partial_{y} \varphi_{0}\right)(y, 0)+\sup _{i \in I_{N}} H_{i}^{-}\left(\partial_{x}^{i} \varphi_{0}(y, 0)\right) & =0 \tag{5.2}
\end{array}
$$

and if $y \neq 0$,

$$
\begin{equation*}
\left(\varphi_{0}-x \partial_{x} \varphi_{0}-y \partial_{y} \varphi_{0}\right)(y, x)+H\left(y,-\partial_{y} \varphi_{0}(y, x)\right)=0 \tag{5.3}
\end{equation*}
$$

and if $y=0$,

$$
\left\{\begin{align*}
\left(\varphi_{0}-x \partial_{x} \varphi_{0}-y \partial_{y} \varphi_{0}\right)(0, x)+\sup _{j \in I_{N}} H_{j}^{-}\left(-\partial_{y}^{j} \varphi_{0}(0, x)\right)=0 & \text { if } N \geq 2,  \tag{5.4}\\
\left(\varphi_{0}-x \partial_{x} \varphi_{0}-y \partial_{y} \varphi_{0}\right)(0, x)+H_{1}\left(-\partial_{y}^{j} \varphi_{0}(0, x)\right)=0 & \text { if } N=1 .
\end{align*}\right.
$$

Moreover, for all $R>0$, there exists $C_{R}>0$ such that for all $x, y \in J$,

$$
\begin{equation*}
d(y, x) \leq R \Rightarrow\left|\partial_{x} \varphi_{0}(y, x)\right|+\left|\partial_{y} \varphi_{0}(y, x)\right| \leq C_{R} \tag{5.5}
\end{equation*}
$$

Remark 5.2. If $I_{0}=I_{N}$, then we have $\mathcal{D}_{0} \in C_{*}^{1}\left(J^{2}\right)$. This good case corresponds to the case where all the $L_{i}(0)$ 's are equal.

Proof of Theorem 3.4. In view of (3.5), we set

$$
\varphi(s, y ; t, x)=(t-s) \varphi_{0}\left(\frac{y}{t-s}, \frac{x}{t-s}\right) .
$$

Now for $y_{0}, x_{0} \in J$ and $0<s_{0}<t_{0}<T$, we define

$$
\tilde{\phi}(t, x)=\varphi\left(s_{0}, y_{0} ; t, x\right) \quad \text { for } \quad(t, x) \in\left(s_{0},+\infty\right) \times J
$$

and

$$
\tilde{\psi}(s, y)=\varphi\left(s, y ; t_{0}, x_{0}\right) \quad \text { for } \quad(s, y) \in\left(-\infty, t_{0}\right) \times J
$$

Without changing the values of $\tilde{\phi}$ (resp. $\tilde{\psi}$ ) in a ball $B\left(P_{0}, r\right)$ for some $r$ small with $P_{0}=\left(t_{0}, x_{0}\right)$ (resp. in a ball $B\left(Q_{0}, r\right)$ for some $r$ small with $\left.Q_{0}=\left(s_{0}, y_{0}\right)\right)$ we can extend it as a function $\phi($ resp. $\psi)$ in $C_{*}^{1}\left(J_{T}\right)$ such that

$$
\phi \geq \mathcal{D}\left(s_{0}, y_{0} ; \cdot, \cdot\right) \quad\left(\text { resp. } \quad \psi \geq \mathcal{D}\left(\cdot, \cdot ; t_{0}, x_{0}\right)\right) \quad \text { on } \quad J_{T}
$$

and $\phi$ and $\psi$ satisfy all the properties announced in Theorem 3.4. This ends the proof of the theorem.

### 5.1 New functions

In view of Lemma 3.2, we recall that optimal curves are of two types: either they reach the junction point, or they stay in a branch and are straight lines. This is the reason why we introduce

$$
\mathcal{D}_{0}(y, x)=\min \left(\mathcal{D}_{\mathrm{str}}(y, x), \mathcal{D}_{\mathrm{jun}}(y, x)\right)
$$

with

$$
\mathcal{D}_{\text {str }}(y, x)= \begin{cases}L_{i}\left(x_{i}-y_{i}\right) & \text { if }(y, x) \in J_{i}^{2} \backslash\{0\}^{2} \\ L_{0}(0) & \text { if } y=0=x \\ +\infty & \text { otherwise }\end{cases}
$$

and

$$
\mathcal{D}_{\text {jun }}(y, x)=\inf _{0 \leq \tau_{1} \leq \tau_{2} \leq 1}\left\{e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)\right\}
$$

where, setting $t=1$ and $s=0$ in (3.10), we get

$$
\left\{\begin{array}{l}
e_{1}\left(\tau_{1}, y\right)= \begin{cases}\tau_{1} L_{j}\left(-\frac{y_{j}}{\tau_{1}}\right)-\tau_{1} L_{0}(0), & \text { for } \quad y=y_{j} e_{j} \neq 0 \\
0, & \text { for } \quad y=0\end{cases}  \tag{5.6}\\
e_{2}\left(\tau_{2}, x\right)= \begin{cases}\left(1-\tau_{2}\right) L_{i}\left(\frac{x_{i}}{1-\tau_{2}}\right)+\tau_{2} L_{0}(0), & \text { for } x=x_{i} e_{i} \neq 0 \\
L_{0}(0), & \text { for } \quad x=0\end{cases}
\end{array}\right.
$$

We will see below that $\mathcal{D}_{\text {jun }}$ is either linear ( $\mathcal{D}_{\text {jun-lin }}$ ) or defined implicitely ( $\mathcal{D}_{\text {jun-imp }}$ ). It will be defined implicitely when the minimum is attained for trajectories reaching the junction point but without staying at it. Precisely, we define on one hand, for $(y, x) \in J^{2}$,

$$
\begin{equation*}
\mathcal{D}_{\text {jun-imp }}(y, x)=\inf _{0 \leq \tau \leq 1}\left\{e_{1}(\tau, y)+e_{2}(\tau, x)\right\} \tag{5.7}
\end{equation*}
$$

It is defined implicitely by $e_{1}(T(y, x), y)+e_{2}(T(y, x), x)$ where $T(y, x)$ is a (the) minimizer (see Lemma 5.8 below for further details). On the other hand, we define for $(y, x) \in J^{j} \times J^{i}$

$$
\begin{equation*}
\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)=-L_{j}^{\prime}\left(\xi_{j}^{-}\right) y+L_{i}^{\prime}\left(\xi_{i}^{+}\right) x+L_{0}(0) . \tag{5.8}
\end{equation*}
$$

See Proposition 5.7 below for a precise statement.

### 5.2 Continuity of $\mathcal{D}_{0}$

The aim of this subsection is to prove the continuity of $\mathcal{D}_{0}$.
Lemma 5.3. (Continuity of $\left.\mathcal{D}_{0}\right)$ The function $\mathcal{D}_{0}$ is continuous in $C\left(J^{2}\right)$.
In order to do so, we first prove the continuity of $\mathcal{D}_{\text {jun }}$.
Lemma 5.4. (Continuity of $\mathcal{D}_{\text {jun }}$ ) The function $\mathcal{D}_{\text {jun }}$ is continuous in $C\left(J^{2}\right)$.

Proof of Lemma 5.4. We already know from Lemma 3.3 that $\mathcal{D}_{\text {jun }}$ is lower semi-continuous and finite. We now show that $\mathcal{D}_{\text {jun }}$ is upper semi-continuous at any point $(y, x)$. We have

$$
\mathcal{D}_{\mathrm{jun}}(y, x)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right) \quad \text { with } \quad 0 \leq \tau_{1} \leq \tau_{2} \leq 1
$$

where we recall that $\tau_{1}>0$ if $y \neq 0$ and $\tau_{2}<1$ if $x \neq 0$. Moreover $e_{1}\left(\tau_{1}, 0\right)=e_{1}(0,0)=0$ and $e_{2}\left(\tau_{2}, 0\right)=e_{2}(1,0)=L_{0}(0)$.

We also consider a sequence $\left(y^{k}, x^{k}\right) \rightarrow(y, x)$, and we want to show that

$$
\begin{equation*}
\mathcal{D}_{\text {jun }}\left(y^{k}, x^{k}\right) \leq \mathcal{D}_{\text {jun }}(y, x)+o_{k}(1) \tag{5.9}
\end{equation*}
$$

This follows (and we will check it in the four cases below) from the inequality

$$
\mathcal{D}_{\mathrm{jun}}\left(y^{k}, x^{k}\right) \leq e_{1}\left(\tau_{1}^{k}, y^{k}\right)+e_{2}\left(\tau_{2}^{k}, x^{k}\right)
$$

with

$\left(\tau_{1}^{k}, \tau_{2}^{k}\right)=\left\{\begin{array}{lllll}\left(\tau_{1},\right. & \left.\tau_{2}\right) & \in(0,1) \times(0,1) & \text { if } & (y, x) \in J^{*} \times J^{*}\end{array} \quad\right.$ (case 1) $)=$| $\left(\left\|y^{k}\right\|\right.$, | $\left.\max \left(\tau_{2},\left\|y^{k}\right\|\right)\right)$ | $\in[0,1) \times[0,1)$ | if $\quad(y, x) \in\{0\} \times J^{*}$ |
| :--- | :--- | :--- | :--- |
| $\left(\min \left(\tau_{1}, 1-\left\|x^{k}\right\|\right)\right.$, | $\left.1-\left\|x^{k}\right\|\right)$ | $\in(0,1] \times(0,1]$ | if $\quad(y, x) \in J^{*} \times\{0\}$ |
| $\left(\left\|y^{k}\right\|\right.$, | $\left.1-\left\|x^{k}\right\|\right)$ | $\in[0,1) \times(0,1]$ | if $\quad(y, x) \in\{0\} \times\{0\}$ |
| (case 2) 3$)$ |  |  |  |
| (case 4) |  |  |  |

Let us recall that

$$
\begin{array}{lll}
e_{1} & \text { is continuous on } & (0,1] \times J^{*} \\
e_{2} & \text { is continuous on } & {[0,1) \times J^{*}} \tag{5.11}
\end{array}
$$

Case 1: $y \in J_{j}^{*}, x \in J_{i}^{*}$. In this case, we have

$$
e_{1}\left(\tau_{1}^{k}, y^{k}\right) \rightarrow e_{1}\left(\tau_{1}, y\right) \quad \text { because of }(5.10)
$$

and

$$
e_{2}\left(\tau_{2}^{k}, x^{k}\right) \rightarrow e_{2}\left(\tau_{2}, x\right) \quad \text { because of }(5.11)
$$

Hence we conclude to (5.9).
Case 2: $y=0, x \in J_{i}^{*}$. We still have $\tau_{2}^{k} \rightarrow \tau_{2}$ and then

$$
e_{2}\left(\tau_{2}^{k}, x^{k}\right) \rightarrow e_{2}\left(\tau_{2}, x\right) \quad \text { because of }(5.11)
$$

We also have (if $y^{k} \in J_{j}$ )

$$
\begin{equation*}
e_{1}\left(\tau_{1}^{k}, y^{k}\right) \leq\left|y^{k}\right| L_{j}\left(-\frac{y_{j}^{k}}{\left|y^{k}\right|}\right)-\left|y^{k}\right| L_{0}(0) \rightarrow 0=e_{1}\left(\tau_{1}, 0\right) \tag{5.12}
\end{equation*}
$$

Hence we conclude to (5.9).

Case 3: $y \in J_{j}^{*}, x=0$. We still have $\tau_{1}^{k} \rightarrow \tau_{1}$ and then

$$
e_{1}\left(\tau_{1}^{k}, y^{k}\right) \rightarrow e_{1}\left(\tau_{1}, y\right) \quad \text { because of }(5.10)
$$

We also have (if $x^{k} \in J_{i}$ )

$$
\begin{equation*}
e_{2}\left(\tau_{2}^{k}, x^{k}\right) \leq\left|x^{k}\right| L_{i}\left(\frac{x_{i}^{k}}{\left|x^{k}\right|}\right)+\left(1-\left|x^{k}\right|\right) L_{0}(0) \rightarrow L_{0}(0)=e_{2}\left(\tau_{2}, 0\right) \tag{5.13}
\end{equation*}
$$

Hence we conclude to (5.9).
Case 4: $y=0, x=0$. We deduce (5.9) from (5.12) and (5.13).
We can now prove Lemma 5.3.
Proof of Lemma 5.3. Notice that for $y=y_{i} e_{i}$ and $x=x_{i} e_{i}$ we have

$$
\mathcal{D}_{\text {jun }}(y, x) \leq \begin{cases}e_{1}(1, y)+e_{2}(1, x) & \text { if } \quad x_{i}=0 \\ e_{1}(0, y)+e_{2}(0, x) & \text { if } \quad y_{i}=0\end{cases}
$$

and then

$$
\mathcal{D}_{\mathrm{jun}}(y, x) \leq L_{i}\left(x_{i}-y_{i}\right) \quad \text { if } \quad y_{i}=0 \quad \text { or } \quad x_{i}=0
$$

Therefore for each $i \in I_{N}$, we have

$$
\mathcal{D}_{\text {jun }}(y, x) \leq \mathcal{D}_{\text {str }}(y, x) \quad \text { for } \quad(y, x) \in \partial\left(J_{i} \times J_{i}\right)=\left(J_{i} \times\{0\}\right) \cup\left(\{0\} \times J_{i}\right)
$$

Therefore we have with $y=y_{i} e_{i}, x=x_{i} e_{i}$

$$
\mathcal{D}_{0}(y, x)= \begin{cases}\min \left(\mathcal{D}_{\text {jun }}(y, x), L_{i}\left(x_{i}-y_{i}\right)\right) & \text { for } \quad(y, x) \in J_{i} \times J_{i} \\ \mathcal{D}_{\mathrm{jun}}(y, x) & \text { for } \quad(y, x) \in \partial\left(J_{i} \times J_{i}\right)\end{cases}
$$

and

$$
\mathcal{D}_{0}(y, x)=\mathcal{D}_{\mathrm{jun}}(y, x) \quad \text { for } \quad(y, x) \in(J \times J) \backslash\left(\bigcup_{j \in I_{N}} J_{j}^{*} \times J_{j}^{*}\right)
$$

This implies that $\mathcal{D}_{0} \in C\left(J^{2}\right)$ and ends the proof of the lemma.
The continuity of $\mathcal{D}_{\text {jun-imp }}$ will be used later on.
Lemma 5.5. (Continuity of $\left.\mathcal{D}_{\text {jun-imp }}^{j i}\right)$ We have $\mathcal{D}_{\text {jun-imp }}^{j i} \in C\left(\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}\right)$ and $\mathcal{D}_{\text {jun-imp }}^{j i} \in C\left(J_{j} \times J_{i}\right)$ if $j \in I_{0}$ or $i \in I_{0}$.

Proof of Lemma 5.5. We proceed as in the proof of Lemma 5.4.
We already know from Lemma 3.3 that $e_{1}$ and $e_{2}$ are lower semi-continuous, and then $\mathcal{D}_{\text {jun-imp }}^{j i}$ is also lower semi-continuous on $J_{j} \times J_{i}$. We now show that $\mathcal{D}_{\text {jun-imp }}^{j i}$ is upper semi-continuous at any point $(y, x) \in\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}$ and also at $(0,0)$ if $j \in I_{0}$ or $i \in I_{0}$. We have

$$
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=e_{1}(\tau, y)+e_{2}(\tau, x) \quad \text { with } \quad 0 \leq \tau \leq 1
$$

where we recall that $\tau>0$ if $y \neq 0$ and $\tau<1$ if $x \neq 0$. Moreover $e_{1}(\tau, 0)=e_{1}(0,0)=0$ and $e_{2}(\tau, 0)=e_{2}(1,0)=L_{0}(0)$.

We also consider a sequence $\left(y^{k}, x^{k}\right) \rightarrow(y, x)$ with $\left(y^{k}, x^{k}\right) \in J_{j} \times J_{i}$, and we want to show that

$$
\begin{equation*}
\mathcal{D}_{\text {jun-imp }}^{j i}\left(y^{k}, x^{k}\right) \leq \mathcal{D}_{\text {jun-imp }}^{j i}(y, x)+o_{k}(1) \tag{5.14}
\end{equation*}
$$

This follows (and we will check it in the cases below) from the inequality

$$
\mathcal{D}_{\text {jun-imp }}^{j i}\left(y^{k}, x^{k}\right) \leq e_{1}\left(\tau^{k}, y^{k}\right)+e_{2}\left(\tau^{k}, x^{k}\right)
$$

with

$$
\tau^{k}=\left\{\begin{array}{llll}
\tau & \in(0,1) & \text { if } \quad(y, x) \in J_{j}^{*} \times J_{i}^{*} & \text { (case 1) } \\
\left|y^{k}\right| & \in[0,1) & \text { if } \quad(y, x) \in\{0\} \times J_{i}^{*} & \text { (case 2) } \\
1-\left|x^{k}\right| \in(0,1] & \text { if } \quad(y, x) \in J_{j}^{*} \times\{0\} & \text { (case 3) } \\
1-\left|x^{k}\right| \in(0,1] & \text { if } \quad(y, x) \in\{0\} \times\{0\} \quad \text { and } \quad j \in I_{0} & \text { (case 4') } \\
\left|y^{k}\right| & \in[0,1) & \text { if } \quad(y, x) \in\{0\} \times\{0\} \quad \text { and } \quad i \in I_{0} & \text { (case 4") }
\end{array}\right.
$$

Case 1: $y \in J_{j}^{*}, x \in J_{i}^{*}$. In this case, we have

$$
e_{1}\left(\tau^{k}, y^{k}\right) \rightarrow e_{1}(\tau, y) \quad \text { because of }(5.10)
$$

and

$$
e_{2}\left(\tau^{k}, x^{k}\right) \rightarrow e_{2}(\tau, x) \quad \text { because of }(5.11)
$$

Hence we conclude to (5.14).
Case 2: $y=0, x \in J_{i}^{*}$. We have $\tau^{k} \rightarrow 0=\tau$ and then

$$
e_{2}\left(\tau^{k}, x^{k}\right) \rightarrow e_{2}(\tau, x) \quad \text { because of }(5.11)
$$

We also have

$$
\begin{equation*}
e_{1}\left(\tau^{k}, y^{k}\right) \leq\left|y^{k}\right| L_{j}\left(-\frac{y_{j}^{k}}{\left|y^{k}\right|}\right)-\left|y^{k}\right| L_{0}(0) \rightarrow 0=e_{1}(\tau, 0) \tag{5.15}
\end{equation*}
$$

Hence we conclude to (5.14).

Case 3: $y \in J_{j}^{*}, x=0$. We still have $\tau^{k} \rightarrow 1=\tau$ and then

$$
e_{1}\left(\tau^{k}, y^{k}\right) \rightarrow e_{1}(\tau, y) \quad \text { because of }(5.10)
$$

We also have

$$
\begin{equation*}
e_{2}\left(\tau^{k}, x^{k}\right) \leq\left|x^{k}\right| L_{i}\left(\frac{x_{i}^{k}}{\left|x^{k}\right|}\right)+\left(1-\left|x^{k}\right|\right) L_{0}(0) \rightarrow L_{0}(0)=e_{2}(\tau, 0) \tag{5.16}
\end{equation*}
$$

Hence we conclude to (5.14).
Case 4': $y=0, x=0, j \in I_{0}$. We have with $\tau^{k}=1-\left|x^{k}\right| \rightarrow 1=\tau$

$$
e_{1}\left(\tau^{k}, y^{k}\right) \leq \tau^{k} L_{j}\left(-\frac{y_{j}^{k}}{\tau^{k}}\right)-\tau^{k} L_{0}(0) \rightarrow L_{j}(0)-L_{0}(0)=0=e_{1}(1,0)=e_{1}(\tau, 0)
$$

We deduce (5.14) from (5.16).
Case 4": $y=0, x=0, i \in I_{0}$
We have with $\tau^{k}=\left|y^{k}\right| \rightarrow 0=\tau$

$$
e_{2}\left(\tau^{k}, x^{k}\right) \leq\left(1-\tau^{k}\right) L_{i}\left(\frac{x_{i}^{k}}{1-\tau^{k}}\right)+\tau^{k} L_{0}(0) \rightarrow L_{i}(0)=L_{0}(0)=e_{2}(0,0)=e_{2}(\tau, 0)
$$

We deduce (5.14) from (5.15). This ends the proof of the lemma.

### 5.3 Study of $\mathcal{D}_{\text {jun }}$

In what follows, we will identify $y_{j}$ with $y=y_{j} e_{j}$, and also identify $x_{i}$ with $x=x_{i} e_{i}$. In order to study $\mathcal{D}_{\text {jun }}$, we introduce the following function for $l \in I_{N}$,

$$
K_{l}(\xi)=L_{l}(\xi)-\xi L_{l}^{\prime}(\xi)-L_{0}(0)
$$

Then we have the following result whose the proof is left to the reader:
Lemma 5.6. (Properties of $K_{l}$ ) Assume (A1). Then for any $l \in I_{N}$, we have

$$
\left\{\begin{array}{l}
K_{l}^{\prime}(\xi) \geq \gamma|\xi| \quad \text { for } \quad \xi \in(-\infty, 0) \\
K_{l}^{\prime}(\xi) \leq-\gamma|\xi| \quad \text { for } \quad \xi \in(0,+\infty)
\end{array}\right.
$$

We define $\left(K_{l}^{-}\right)^{-1}$ as the inverse of the function $K_{l}$ restricted to $(-\infty, 0]$, and $\left(K_{l}^{+}\right)^{-1}$ as the inverse of the function $K_{l}$ restricted to $[0,+\infty)$. We set

$$
\xi_{l}^{ \pm}=\left(K_{l}^{ \pm}\right)^{-1}(0)
$$

Then we have

$$
\begin{cases} \pm \xi_{l}^{ \pm}=0 & \text { if } \quad l \in I_{0} \\ \pm \xi_{l}^{ \pm}>0 & \text { if } \quad l \in I_{N} \backslash I_{0}\end{cases}
$$

Moreover we have

$$
\begin{equation*}
K_{l}(\xi)=-H_{l}\left(L_{l}^{\prime}(\xi)\right)-L_{0}(0) \tag{5.17}
\end{equation*}
$$

Proposition 5.7. (Properties on $J_{j}^{*} \times J_{i}^{*}$ ) Assume (A1). Recall that $\mathcal{D}_{\text {jun-imp }}$ and $\mathcal{D}_{\text {jun-lin }}$ are defined in (5.7) and (5.8). We also consider

Then we have

$$
\mathcal{D}_{\mathrm{jun}}^{j i}(y, x)= \begin{cases}\mathcal{D}_{\mathrm{jun-lin}}^{j i}(y, x) & \text { if } \quad(y, x) \in \Delta^{j i} \\ \mathcal{D}_{\mathrm{jun-imp}}^{j i}(y, x) & \text { if } \quad(y, x) \in\left(J_{j} \times J_{i}\right) \backslash \Delta^{j i}\end{cases}
$$

Then the functions $\mathcal{D}_{\text {jun }}^{j, i}, \mathcal{D}_{\text {jun-lin }}^{j, i}$ and $\mathcal{D}_{\text {jun-imp }}^{j, i}$ are convex and $C^{1}$ in $J_{j}^{*} \times J_{i}^{*}$ and, if $\tilde{\mathcal{D}}$ is one of them, it satisfies for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$

$$
\left\{\begin{array}{l}
\tilde{\mathcal{D}}(y, x)-x \partial_{x} \tilde{\mathcal{D}}(y, x)-y \partial_{y} \tilde{\mathcal{D}}(y, x)+H_{i}\left(\partial_{x} \tilde{\mathcal{D}}(y, x)\right)=0,  \tag{5.18}\\
\tilde{\mathcal{D}}(y, x)-x \partial_{x} \tilde{\mathcal{D}}(y, x)-y \partial_{y} \tilde{\mathcal{D}}(y, x)+H_{j}\left(-\partial_{y} \tilde{\mathcal{D}}(y, x)\right)=0 .
\end{array}\right.
$$

Moreover for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$, there exists a unique $\tau=T(y, x) \in(0,1)$ such that

$$
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=e_{1}(\tau, y)+e_{2}(\tau, x) ;
$$

for such a $\tau$, we also have

$$
\left\{\begin{array}{lll}
\partial_{x} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=L_{i}^{\prime}\left(\xi_{x}\right) & \text { with } & \xi_{x}=\frac{x}{1-\tau}, \\
\partial_{y} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=-L_{j}^{\prime}\left(\xi_{y}\right) & \text { with } & \xi_{y}=-\frac{y}{\tau} .
\end{array}\right.
$$

Proof of Proposition 5.7. The proof proceeds in several steps.
Step 1: first study of $\mathcal{D}_{\text {jun }}^{j i}$. Let us define

$$
G_{0}\left(\tau_{1}, \tau_{2}, y, x\right)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)
$$

For $\tau_{1}, \tau_{2} \in(0,1)$, and setting

$$
\begin{equation*}
\xi_{y}=-\frac{y}{\tau_{1}}, \quad \xi_{x}=\frac{x}{1-\tau_{2}} \tag{5.19}
\end{equation*}
$$

and $V_{y}=\left(\xi_{y}, 0,1,0\right)$ and $V_{x}=\left(0, \xi_{x}, 0,1\right)$, we compute

$$
D^{2} G_{0}\left(\tau_{1}, \tau_{2}, y, x\right)=\frac{L_{j}^{\prime \prime}\left(\xi_{y}\right)}{\tau_{1}} V_{y}^{T} V_{y}+\frac{L_{i}^{\prime \prime}\left(\xi_{x}\right)}{1-\tau_{2}} V_{x}^{T} V_{x} \geq 0
$$

Therefore $G_{0}$ is in particular convex on $(0,1) \times(0,1) \times J_{j}^{*} \times J_{i}^{*}$. Because $G_{0}$ is in particular lower semi-continuous on $[0,1] \times[0,1] \times J_{j}^{*} \times J_{i}^{*}$ (by Lemma 3.3), and

$$
\begin{equation*}
G_{0}\left(0, \tau_{2}, y, x\right)=+\infty=G_{0}\left(\tau_{1}, 1, y, x\right) \quad \text { for } \quad(y, x) \in J_{j}^{*} \times J_{i}^{*} \tag{5.20}
\end{equation*}
$$

we deduce that

$$
\mathcal{D}_{\text {jun }}^{j i}(y, x)=\inf _{0<\tau_{1} \leq \tau_{2}<1} G_{0}\left(\tau_{1}, \tau_{2}, y, x\right) \quad \text { for } \quad(y, x) \in J_{j}^{*} \times J_{i}^{*}
$$

This implies that $\mathcal{D}_{\text {jun }}^{j i}$ is also convex on $J_{j}^{*} \times J_{i}^{*}$. Notice that in particular

$$
D_{\tau_{1} \tau_{1}}^{2} G_{0}\left(\tau_{1}, \tau_{2}, y, x\right)=\frac{y^{2}}{\tau_{1}^{3}} L_{j}^{\prime \prime}\left(\xi_{y}\right)>0
$$

and

$$
D_{\tau_{2} \tau_{2}}^{2} G_{0}\left(\tau_{1}, \tau_{2}, y, x\right)=\frac{x^{2}}{\left(1-\tau_{2}\right)^{3}} L_{i}^{\prime \prime}\left(\xi_{x}\right)>0
$$

The map $\left(\tau_{1}, \tau_{2}\right) \mapsto G_{0}\left(\tau_{1}, \tau_{2}, y, x\right)$ is then strictly convex on the convex set

$$
\left\{\left(\tau_{1}, \tau_{2}\right) \in(0,1)^{2}, \quad \tau_{1} \leq \tau_{2}\right\}
$$

Therefore using again (5.20) and the lower semi-continuity of $G_{0}$, we deduce that it has a unique minimum that we denote by $\left(\tau_{1}, \tau_{2}\right)$ satisfying $0<\tau_{1} \leq \tau_{2}<1$.
Step 2: study of $\mathcal{D}_{\text {jun-imp }}^{j i}$. Let us consider the following function

$$
e(\tau, y, x)=G_{0}(\tau, \tau, y, x)
$$

For $\tau \in(0,1)$, setting

$$
\xi_{y}=-\frac{y}{\tau}, \quad \xi_{x}=\frac{x}{1-\tau}
$$

and proceeding similarly as in Step 1, we can deduce that

$$
\mathcal{D}_{\mathrm{jun-imp}}^{j i}(y, x)=\inf _{\tau \in(0,1)} e(\tau, y, x) \quad \text { for } \quad(y, x) \in J_{j}^{*} \times J_{i}^{*}
$$

and that $\mathcal{D}_{\text {jun-imp }}^{j i}$ is also convex on $J_{j}^{*} \times J_{i}^{*}$. We can also deduce that the map $\tau \mapsto e(\tau, y, x)$ is strictly convex on $(0,1)$ for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$ and that it has a unique minimum that we denote by $\tau \in(0,1)$ such that

$$
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=e(\tau, y, x)
$$

Using the derivative with respect to $\tau$, we see that $\tau$ is characterized by the equation

$$
\begin{equation*}
F=0 \quad \text { with } \quad F(\tau, y, x):=K_{j}\left(-\frac{y}{\tau}\right)-K_{i}\left(\frac{x}{1-\tau}\right) \tag{5.21}
\end{equation*}
$$

Moreover

$$
\partial_{\tau} F(\tau, y, x)=D_{\tau \tau}^{2} e(\tau, y, x)>0 .
$$

Using the regularity $C^{2}$ of $L_{l}$ given in assumption (A1), we see that the unique solution $\tau=T(y, x)$ of $F(\tau, y, x)=0$ is continuously differentiable with respect to $(y, x)$. Therefore we deduce that $\mathcal{D}_{\text {jun-imp }}^{j i} \in C^{1}\left(J_{j}^{*} \times J_{i}^{*}\right)$.

We have

$$
\begin{align*}
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x) & =e_{1}(T(y, x), y)+e_{2}(T(y, x), x),  \tag{5.22}\\
\partial_{y} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x) & =\left(\partial_{y} e_{1}\right)(T(y, x), y)=-L_{j}^{\prime}\left(\xi_{y}\right),  \tag{5.23}\\
\partial_{x} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x) & =\left(\partial_{x} e_{2}\right)(T(y, x), x)=L_{i}^{\prime}\left(\xi_{x}\right) . \tag{5.24}
\end{align*}
$$

Writing $\tau$ for $T(y, x)$, and using the optimality condition (5.21), we get

$$
\begin{aligned}
\left(\mathcal{D}_{\text {jun-imp }}^{j i}-x \partial_{x} \mathcal{D}_{\text {jun-imp }}^{j i}-y \partial_{y} \mathcal{D}_{\text {jun-imp }}^{j i}\right)(y, x) & =\tau K_{j}\left(-\frac{y}{\tau}\right)+(1-\tau) K_{i}\left(\frac{x}{1-\tau}\right)+L_{0}(0) \\
& =K_{j}\left(-\frac{y}{\tau}\right)+L_{0}(0)=-H_{j}\left(L_{j}^{\prime}\left(-\frac{y}{\tau}\right)\right) \\
& =-H_{j}\left(-\partial_{y} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x)\right) \\
& =K_{i}\left(\frac{x}{1-\tau}\right)+L_{0}(0)=-H_{i}\left(L_{i}^{\prime}\left(\frac{x}{1-\tau}\right)\right) \\
& =-H_{i}\left(\partial_{x} \mathcal{D}_{\text {jun-imp }}^{j i}(y, x)\right) W e
\end{aligned}
$$

where we have used (5.17) in the second and in the fourth line. Hence $\mathcal{D}_{\text {jun-imp }}^{j i}$ satisfies (5.18) on $J_{j}^{*} \times J_{i}^{*}$.

Step 3: further study of $\mathcal{D}_{\text {jun }}^{j i}$. We concluded at the end of Step 1 that for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$ we have

$$
\mathcal{D}_{\text {jun }}^{j i}(y, x)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)
$$

with $0<\tau_{1} \leq \tau_{2}<1$. Then we can distinguish two cases.
Case 1: $\tau_{1}<\tau_{2}$. In that case this implies that

$$
\partial_{\tau_{1}} e_{1}\left(\tau_{1}, y\right)=0, \quad \partial_{\tau_{2}} e_{2}\left(\tau_{2}, x\right)=0
$$

which can be written as

$$
\begin{equation*}
K_{j}\left(\xi_{y}\right)=0, \quad K_{i}\left(\xi_{x}\right)=0 \tag{5.25}
\end{equation*}
$$

with $\xi_{y} \leq 0 \leq \xi_{x}$ defined in (5.19).
Using Lemma 5.6, we conclude that (5.25) holds true if and only if $K_{j}(0)>0$ and $K_{i}(0)>0$; i.e. $j, i \in I_{N} \backslash I_{0}$. In this case we have $\xi_{y}=\xi_{j}^{-}$and $\xi_{x}=\xi_{i}^{+}$and then

$$
\begin{equation*}
\tau_{1}=-\frac{y}{\xi_{j}^{-}}, \quad \tau_{2}=1-\frac{x}{\xi_{i}^{+}} \tag{5.26}
\end{equation*}
$$

Moreover, we have in this case

$$
\begin{aligned}
\mathcal{D}_{\text {jun }}^{j i}(y, x) & =-\left(\frac{L_{j}\left(\xi_{j}^{-}\right)}{\xi_{j}^{-}}-\frac{L_{0}(0)}{\xi_{j}^{-}}\right) y+\left(\frac{L_{i}\left(\xi_{i}^{+}\right)}{\xi_{i}^{+}}-\frac{L_{0}(0)}{\xi_{i}^{+}}\right) x+L_{0}(0) \\
& =\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)
\end{aligned}
$$

with

$$
\begin{equation*}
\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)=-L_{j}^{\prime}\left(\xi_{j}^{-}\right) y+L_{i}^{\prime}\left(\xi_{i}^{+}\right) x+L_{0}(0) . \tag{5.27}
\end{equation*}
$$

Using Legendre-Fenchel's equality together with $K_{j}\left(\xi_{j}^{-}\right)=0$ and $K_{i}\left(\xi_{i}^{+}\right)=0$, we have

$$
\begin{equation*}
\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)-y \partial_{y} \mathcal{D}_{\text {jun-lin }}^{j i}(y, x)-x \partial_{x} \mathcal{D}_{\text {jun-lin }}^{j i}(y, x)=L_{0}(0), \tag{5.28}
\end{equation*}
$$

and

$$
H_{i}\left(\partial_{x} \mathcal{D}_{\text {jun-lin }}^{j i}(y, x)\right)=H_{i}\left(L_{i}^{\prime}\left(\xi_{i}^{+}\right)\right)=\xi_{i}^{+} L_{i}^{\prime}\left(\xi_{i}^{+}\right)-L_{i}\left(\xi_{i}^{+}\right)=-L_{0}(0),
$$

and

$$
H_{j}\left(-\partial_{y} \mathcal{D}_{\text {jun-lin }}^{j i}(y, x)\right)=H_{j}\left(L_{j}^{\prime}\left(\xi_{j}^{-}\right)\right)=\xi_{j}^{-} L_{j}^{\prime}\left(\xi_{j}^{-}\right)-L_{j}\left(\xi_{j}^{-}\right)=-L_{0}(0)
$$

Hence $\mathcal{D}_{\text {jun-lin }}^{j i}$ satisfies (5.18) on $J_{j}^{*} \times J_{i}^{*}$.
Finally we deduce from (5.26) that the condition: $0<\tau_{1}<\tau_{2}<1$ is equivalent to $(y, x) \in \Delta^{j i} \cap\left(J^{*}\right)^{2}$ and then by continuity of $\mathcal{D}_{\text {jun }}^{j i}$ and $\mathcal{D}_{\text {jun-lin }}^{j i}$, we get

$$
\mathcal{D}_{\mathrm{jun}}^{j i}=\mathcal{D}_{\mathrm{jun-lin}}^{j i} \quad \text { on } \quad \Delta^{j i} .
$$

Case 2: $\tau_{1}=\tau_{2}$. If for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$ we have

$$
\mathcal{D}_{\mathrm{jun}}^{j i}(y, x)=e_{1}\left(\tau_{1}, y\right)+e_{2}\left(\tau_{2}, x\right)
$$

with $\tau_{1}=\tau_{2}$, then we have seen that $(y, x) \in\left(J_{j}^{*} \times J_{i}^{*}\right) \backslash \Delta^{j i}$ and $\mathcal{D}_{\text {jun }}^{j i}(y, x)=\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)$. From Lemma 5.5, we also have that $\mathcal{D}_{\text {jun-imp }}^{j i} \in C\left(J_{j} \times J_{i}\right)$ if $j \in I_{0}$ or $i \in I_{0}$ and in that case $\Delta^{j i}=\emptyset$. On the other hand, we have $\mathcal{D}_{\text {jun-imp }}^{j i} \in C\left(\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}\right)$ if $j, i \in I_{N} \backslash I_{0}$ with $\{0\}^{2} \in \Delta^{i j}$ in that case. Therefore in all cases we have

$$
\mathcal{D}_{\text {jun-imp }}^{j i} \in C\left(\left(J_{j} \times J_{i}\right) \backslash \Delta^{j i}\right)
$$

Now from the continuity of $\mathcal{D}_{\text {jun }}$, we deduce that

$$
\mathcal{D}_{\text {jun }}^{j i}=\mathcal{D}_{\text {jun-imp }}^{j i} \quad \text { on } \quad\left(J_{j} \times J_{i}\right) \backslash \Delta^{j i} .
$$

Step 4: on the boundary $\left(\partial \Delta^{j i}\right) \cap\left(J^{*}\right)^{2}$. We already know that $\mathcal{D}_{\text {jun }}$ is continuous, therefore if $j, i \in I_{N} \backslash I_{0}$ :

$$
\mathcal{D}_{\text {jun-lin }}^{j i}=\mathcal{D}_{\text {jun-imp }}^{j i} \quad \text { on } \quad\left\{(y, x) \in J_{j} \times J_{i}, \quad \frac{x}{\xi_{i}^{+}}-\frac{y}{\xi_{j}^{-}}=1\right\}
$$

On the other hand, recall that $(y, x) \in J_{j}^{*} \times J_{i}^{*}$, the real $\tau \in(0,1)$ is characterized by (5.21), i.e.

$$
\begin{equation*}
K_{j}\left(\xi_{y}\right)=K_{i}\left(\xi_{x}\right) \quad \text { with } \quad \xi_{y}=-\frac{y}{\tau}, \quad \xi_{x}=\frac{x}{1-\tau} . \tag{5.29}
\end{equation*}
$$

Notice that if we choose

$$
\tau=-\frac{y}{\xi_{j}^{-}}
$$

we deduce from $\frac{x}{\xi_{i}^{+}}-\frac{y}{\xi_{j}^{-}}=1$ that

$$
\begin{equation*}
\xi_{y}=\xi_{j}^{-} \quad \text { and } \quad \xi_{x}=\xi_{i}^{+} \tag{5.30}
\end{equation*}
$$

which are obvious solutions of $(5.29)$. Therefore we conclude that this is the solution. Using (5.23)-(5.24) and the expression (5.27) of $\mathcal{D}_{\text {jun-lin }}^{j i}$, (5.30) implies the equality of the gradients of $\mathcal{D}_{\text {jun-lin }}^{j i}$ and $\mathcal{D}_{\text {jun-imp }}^{j i}$ on the boundary $\left(\partial \Delta^{j i}\right) \cap\left(J^{*}\right)^{2}$. Finally this shows that $\mathcal{D}_{\mathrm{jun}}^{j i} \in C^{1}\left(J_{j}^{*} \times J_{i}^{*}\right)$. This ends the proof of the proposition.
Lemma 5.8. (Uniqueness and continuity of $T$ ) There is a unique $\tau=T(y, x) \in[0,1]$ such that

$$
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=e_{1}(\tau, y)+e_{2}(\tau, x) \quad \text { if } \quad(y, x) \in\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}
$$

Moreover we have $T \in C\left(\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}\right)$. We have with $\tau=T(y, x)$

$$
\left\{\begin{array}{l}
\tau=\max \left(0,1-\frac{x}{\xi_{i}^{+}}\right) \quad \text { if } \quad(y, x) \in\left(\{0\} \times J_{i}^{*}\right) \backslash \Delta^{j i}, \\
\tau=\min \left(1,-\frac{y}{\xi_{j}^{-}}\right) \quad \text { if } \quad(y, x) \in\left(J_{j}^{*} \times\{0\}\right) \backslash \Delta^{j i}
\end{array}\right.
$$

Proof of Lemma 5.8. The proof proceeds in several steps.
Step 1: continuity of $T$. We set for $(\tau, y, x) \in[0,1] \times J_{j} \times J_{i}$

$$
e(\tau, y, x)=e_{1}(\tau, y)+e_{2}(\tau, x)
$$

From Proposition 5.7, we already know that there exists a unique $\tau \in[0,1]$ such that

$$
\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)=e(\tau, y, x) \quad \text { if } \quad(y, x) \in J_{j}^{*} \times J_{i}^{*}
$$

On the other hand, we have

$$
e(\tau, y, x)=\left\{\begin{array}{lcc}
(1-\tau) L_{i}\left(\frac{x}{1-\tau}\right)+\tau L_{0}(0) & \text { if } & (y, x) \in\{0\} \times J_{i}^{*}  \tag{5.31}\\
\tau L_{j}\left(-\frac{y}{\tau}\right)+(1-\tau) L_{0}(0) & \text { if } \quad(y, x) \in J_{j}^{*} \times\{0\} & (\text { case 1) } \\
\text { case 2) }
\end{array}\right.
$$

Notice that in Cases 1 and 2, there is a unique $\tau \in[0,1]$ such that

$$
\begin{equation*}
\mathcal{D}_{\mathrm{jun}-\mathrm{imp}}^{j i}(y, x)=e(\tau, y, x) \tag{5.32}
\end{equation*}
$$

and $\tau \in[0,1)$ in case $1, \tau \in(0,1]$ in case 2 . Then the continuity of $\tau=T(y, x)$ in $\left(J_{j} \times J_{i}\right) \backslash\{0\}^{2}$ follows from the lower semi-continuity of $e$ on $[0,1] \times J_{j} \times J_{i}$ and the uniqueness of $\tau$ such that (5.32) holds.
Step 2: computation of $T$. We distinguish cases.
Case 1: $(y, x) \in\left(\{0\} \times J_{i}^{*}\right) \backslash \Delta^{j i}$. Notice that we have

$$
\partial_{\tau} e(\tau, 0, x)=-K_{i}\left(\xi_{x}\right) \quad \text { with } \quad \xi_{x}=\frac{x}{1-\tau} .
$$

Subcase 1.1: $x \geq \xi_{i}^{+}$. Therefore

$$
\partial_{\tau} e(\tau, 0, x) \geq 0
$$

and

$$
T(0, x)=0
$$

Subcase 1.2: $x<\xi_{i}^{+}$. Then $\xi_{x}=\xi_{i}^{+}$is a solution of $\partial_{\tau} e(\tau, 0, x)=-K_{i}\left(\xi_{x}\right)=0$ and

$$
T(0, x)=1-\frac{x}{\xi_{i}^{+}} .
$$

Case 2: $(y, x) \in\left(J_{j}^{*} \times\{0\}\right) \backslash \Delta^{j i}$. Notice that we have

$$
\partial_{\tau} e(\tau, y, 0)=K_{j}\left(\xi_{y}\right) \quad \text { with } \quad \xi_{y}=-\frac{y}{\tau} .
$$

Subcase 2.1: $y \geq-\xi_{j}^{-}$. Therefore

$$
\partial_{\tau} e(\tau, y, 0) \leq 0
$$

and

$$
T(y, 0)=1
$$

Subcase 2.2: $y<-\xi_{j}^{-}$. Then $\xi_{y}=\xi_{j}^{-}$is a solution of $\partial_{\tau} e(\tau, y, 0)=K_{j}\left(\xi_{y}\right)=0$ and

$$
T(y, 0)=-\frac{y}{\xi_{j}^{-}}
$$

This ends the proof of the lemma.
Lemma 5.9. (Boundary regularity of $\left.\mathcal{D}_{\text {jun }}^{j i}\right)$ Then we have $\mathcal{D}_{\text {jun }}^{j i} \in C^{1}\left(J_{j} \times J_{i}\right)$ with

$$
\left\{\begin{array}{l}
\partial_{x} \mathcal{D}_{\mathrm{jun}}^{j i}(y, x)=L_{i}^{\prime}\left(\xi_{x}\right)  \tag{5.33}\\
\partial_{y} \mathcal{D}_{\mathrm{jun}}^{j i}(y, x)=-L_{j}^{\prime}\left(\xi_{y}\right)
\end{array}\right.
$$

where $\xi_{y} \leq 0 \leq \xi_{x}$ satisfy

$$
\left\{\begin{array}{lll}
\xi_{x}=\max \left(x, \xi_{i}^{+}\right), & \xi_{y}=\left(K_{j}^{-}\right)^{-1}\left(K_{i}\left(\xi_{x}\right)\right) & \text { if }(y, x) \in\left(\{0\} \times J_{i}\right) \backslash \Delta^{j i}  \tag{5.34}\\
\xi_{x}=\xi_{i}^{+}, & \xi_{y}=\xi_{j}^{-} & \text {if }(y, x) \in\left(\{0\} \times J_{i}\right) \cap \Delta^{j i} \\
\xi_{x}=\left(K_{i}^{+}\right)^{-1}\left(K_{j}\left(\xi_{y}\right)\right), & \xi_{y}=-\max \left(y,-\xi_{j}^{-}\right) & \text {if }(y, x) \in\left(J_{j} \times\{0\}\right) \backslash \Delta^{j i} \\
\xi_{x}=\xi_{i}^{+}, & \xi_{y}=\xi_{j}^{-} & \text {if }(y, x) \in\left(J_{j} \times\{0\}\right) \cap \Delta^{j i}
\end{array}\right.
$$

Moreover we have

$$
\begin{cases}\mathcal{D}_{\text {jun }}^{j i}(0, x)=\frac{x}{\xi_{x}}\left(L_{i}\left(\xi_{x}\right)-L_{0}(0)\right)+L_{0}(0) & \text { for }  \tag{5.35}\\ \left.\mathcal{D}_{\text {jun }}^{j i}(y, 0)\right)=-\frac{y}{\xi_{y}}\left(L_{j}\left(\xi_{y}\right)-L_{0}^{*}(0)\right)+L_{0}(0) & \text { for } \\ y \in J_{j}^{*}\end{cases}
$$

and

$$
\begin{align*}
\mathcal{D}_{\text {jun }}^{j i}(x, y)-x \partial_{x} \mathcal{D}_{\text {jun }}^{j i}(x, y)-y \partial_{y} \mathcal{D}_{\text {jun }}^{j i}(x, y)
\end{align*} \quad \begin{array}{ll}
L_{0}(0)+K_{i}\left(\max \left(x, \xi_{i}^{+}\right)\right) & \text {if }(y, x) \in\{0\} \times J_{i}, \\
L_{0}(0)+K_{j}\left(-\max \left(y,-\xi_{j}^{-}\right)\right) & \text {if }(y, x) \in J_{j} \times\{0\} . \tag{5.36}
\end{array}
$$

Proof of Lemma 5.9. The proof proceeds in several steps.
Step 1: continuity. From Proposition 5.7, we already know that $\mathcal{D}_{\text {jun }}^{j i} \in C^{1}\left(\left(J_{j}^{*} \times J_{i}^{*}\right) \cup\right.$ $\Delta^{j i}$ ) and (5.33) holds true with

$$
\left\{\begin{array}{lll}
\xi_{x}=\frac{x}{1-\tau}, & \xi_{y}=-\frac{y}{\tau} & \text { if } \\
\xi_{x}=\xi_{i}^{+}, & \xi_{y}=\xi_{j}^{-} & \text {if } \quad(y, x) \in\left(J_{j}^{*} \times J_{i}^{*}\right) \backslash \Delta^{j i} \\
\Delta^{j i}
\end{array}\right.
$$

where $\tau=T(y, x)$ in the first line. Therefore, in order to prove that $\mathcal{D}_{\text {jun }}^{j i} \in C^{1}\left(J_{j} \times J_{i}\right)$, it is sufficient to prove that if $(y, x) \in\left(\partial\left(J_{j} \times J_{i}\right)\right) \backslash \Delta^{j i}=\left(\left(\{0\} \times J_{i}\right) \times\left(J_{j} \times\{0\}\right)\right) \backslash \Delta^{j i}$, and if $\left(y^{k}, x^{k}\right) \in\left(J_{j}^{*} \times J_{i}^{*}\right) \backslash \Delta^{j i}$ is a sequence of points such that $\left(y^{k}, x^{k}\right) \rightarrow(y, x)$, then we have with $\tau^{k}=T\left(y^{k}, x^{k}\right)$

$$
\begin{equation*}
-\frac{y^{k}}{\tau^{k}} \rightarrow \xi_{y} \quad \text { and } \quad \frac{x^{k}}{1-\tau^{k}} \rightarrow \xi_{x} \tag{5.37}
\end{equation*}
$$

where $\left(\xi_{y}, \xi_{x}\right)$ is given by (5.34). Let us recall that $\tau^{k}$ is characterized by the equation

$$
\begin{equation*}
K_{j}\left(-\frac{y^{k}}{\tau^{k}}\right)=K_{i}\left(\frac{x^{k}}{1-\tau^{k}}\right) \tag{5.38}
\end{equation*}
$$

We will assume (up to extract a subsequence) that $\tau^{k} \rightarrow \tau_{0}$ for some limit $\tau_{0} \in[0,1]$. Because we have $\left|x^{k}\right|^{2}+\left|y^{k}\right|^{2} \leq R^{2}$, it is easy to deduce from (5.38), that there exists a constant $C_{R}$ such that

$$
\begin{equation*}
\left|-\frac{y^{k}}{\tau^{k}}\right|+\left|\frac{x^{k}}{1-\tau^{k}}\right| \leq C_{R} \tag{5.39}
\end{equation*}
$$

This can be proved by contradiction, distinguishing the cases $\tau_{0}=0, \tau_{0}=1$ and $\tau_{0} \in(0,1)$. Up to extract a subsequence, we can then pass to the limit in (5.38) and get

$$
\begin{equation*}
K_{j}\left(\xi_{y}\right)=K_{i}\left(\xi_{x}\right) \quad \text { with } \quad \xi_{y} \leq 0 \leq \xi_{x} \tag{5.40}
\end{equation*}
$$

In the following cases, we now identify one of the two quantities $\xi_{y}$ or $\xi_{x}$, the other one being determined by (5.40).
Case 1: $(y, x) \in\left(\{0\} \times J_{i}^{*}\right) \backslash \Delta^{j i}$. From Lemma 5.8, we know that $\tau_{0}=\max \left(0,1-\frac{x}{\xi_{i}^{+}}\right)$, and then

$$
\xi_{x}=\max \left(x, \xi_{i}^{+}\right), \quad \xi_{y}=\left(K_{j}^{-}\right)^{-1}\left(K_{i}\left(\xi_{x}\right)\right)
$$

and from (5.31), we get

$$
\begin{equation*}
\mathcal{D}_{\mathrm{jun}}^{j i}(0, x)=\frac{x}{\xi_{x}}\left(L_{i}\left(\xi_{x}\right)-L_{0}(0)\right)+L_{0}(0) \tag{5.41}
\end{equation*}
$$

Case 2: $(y, x) \in\left(J_{j}^{*} \times\{0\}\right) \backslash \Delta^{j i}$. From Lemma 5.8, we know that $\tau_{0}=\min \left(1,-\frac{y}{\xi_{j}^{-}}\right)$, and then

$$
-\xi_{y}=\max \left(y,-\xi_{j}^{-}\right), \quad \xi_{x}=\left(K_{i}^{+}\right)^{-1}\left(K_{j}\left(\xi_{y}\right)\right)
$$

and from (5.31), we get

$$
\begin{equation*}
\mathcal{D}_{\mathrm{jun}}^{j i}(y, 0)=-\frac{y}{\xi_{y}}\left(L_{j}\left(\xi_{y}\right)-L_{0}(0)\right)+L_{0}(0) \tag{5.42}
\end{equation*}
$$

Case 3: $(y, x) \in\{0\}^{2} \backslash \Delta^{j i}$. This case only occurs if $j \in I_{0}$ or $i \in I_{0}$. Moreover at least one of the two quantities $-\frac{y^{k}}{\tau^{k}}$ and $\frac{x^{k}}{1-\tau^{k}}$ tends to zero.

If $\xi_{y}=0$, then $K_{i}\left(\xi_{x}\right)=K_{j}(0)$ and hence

$$
\xi_{y}=0 \quad \Longrightarrow \quad L_{i}(0) \geq L_{j}(0)=L_{0}(0)
$$

If $\xi_{x}=0$, then $K_{j}\left(\xi_{y}\right)=K_{i}(0)$ and hence

$$
\xi_{x}=0 \quad \Longrightarrow \quad L_{j}(0) \geq L_{i}(0)=L_{0}(0)
$$

This implies that

$$
\left\{\begin{array}{llll}
\xi_{x}=\xi_{i}^{+}=0, & \xi_{y}=\xi_{j}^{-}<0, & \text { if } & L_{i}(0)=L_{0}(0)<L_{j}(0) \\
\xi_{x}=\xi_{i}^{+}>0, & \xi_{y}=\xi_{j}^{-}=0, & \text { if } & L_{i}(0)>L_{j}(0)=L_{0}(0) \\
\xi_{x}=\xi_{i}^{+}=0, & \xi_{y}=\xi_{j}^{-}=0, & \text { if } & L_{i}(0)=L_{j}(0)=L_{0}(0)
\end{array}\right.
$$

By the uniqueness of the limit, this finally shows that $\mathcal{D}_{\text {jun }}^{j i} \in C^{1}\left(J_{j} \times J_{i}\right)$ and (5.34) holds.
Step 2: checking (5.31) and (5.36). From (5.41) and (5.42), we deduce (5.31) on $\left(\left(J_{j}^{*} \times\{0\}\right) \cup\left(\{0\} \times J_{i}^{*}\right)\right) \backslash \Delta^{j i}$. From $\mathcal{D}_{\text {jun }}^{j i}=\mathcal{D}_{\text {jun-lin }}^{j i}$ on $\Delta^{j i}$, we deduce that (5.31) is also true on $\left(\left(J_{j}^{*} \times\{0\}\right) \cup\left(\{0\} \times J_{i}^{*}\right)\right) \cap \Delta^{j i}$.

Then (5.36) follows from a simple computation for $(y, x) \neq(0,0)$. This is still true for $(y, x)=0$, because $\mathcal{D}_{\text {jun }}^{j i}$ is $C^{1}$. This ends the proof of the lemma.

Lemma 5.10. (Properties of $\mathcal{D}_{\mathrm{str}}^{j i}$ ) For $j=i \in I_{N}$, we have for $(y, x) \in J_{j} \times J_{i}$ with $(y, x) \neq(0,0)$ if $j=i \in I_{N} \backslash I_{0}$ :

$$
\mathcal{D}_{\mathrm{str}}^{j i}(y, x)-x \partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)-y \partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)=\left\{\begin{array}{l}
L_{0}(0)+K_{i}(x-y) \\
-H_{i}\left(\partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)\right) \\
-H_{j}\left(-\partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)\right)
\end{array}\right.
$$

and

$$
\partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)=L_{i}^{\prime}(\xi), \quad \partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)=-L_{j}^{\prime}(\xi) \quad \text { with } \quad \xi=x-y
$$

Proof of Lemma 5.10. We compute

$$
\partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)=L_{i}^{\prime}(x-y), \quad \partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)=-L_{i}^{\prime}(x-y)
$$

and

$$
\begin{aligned}
\mathcal{D}_{\mathrm{str}}^{j i}(y, x)-x \partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)-y \partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x) & =K_{i}(x-y)+L_{0}(0) \\
& =-H_{i}\left(L_{i}^{\prime}(x-y)\right) \\
& =-H_{i}\left(\partial_{x} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)\right) \\
& =-H_{i}\left(-\partial_{y} \mathcal{D}_{\mathrm{str}}^{j i}(y, x)\right)
\end{aligned}
$$

### 5.4 Proof of Theorem 5.1

We are now in position to prove Theorem 5.1. We prove two lemmas successively.
Lemma 5.11. (Properties of $\left.\mathcal{D}_{0}^{j i}\right)$ For $(y, x) \in J_{j} \times J_{i}$, we have

$$
\mathcal{D}_{0}^{j i}(y, x)= \begin{cases}\mathcal{D}_{\mathrm{jun}}^{j i}(y, x) & \text { if } i \neq j \\ L_{i}(x-y) & \text { if } i=j \in I_{0} \\ \min \left(\mathcal{D}_{\text {jun }}^{j i}(y, x), L_{i}(x-y)\right) & \text { if } i=j \in I_{N} \backslash I_{0}\end{cases}
$$

with for $i=j \in I_{N} \backslash I_{0}$

$$
\mathcal{D}_{0}^{j i}(y, x)= \begin{cases}\mathcal{D}_{\text {jun-lin }}^{j i} & \text { in a neighborhood of any point of } \quad\left(\partial\left(J_{j} \times J_{i}\right)\right) \cap \Delta^{j i}  \tag{5.43}\\ L_{i}(x-y) & \text { in a neighborhood of any point of } \quad\left(\partial\left(J_{j} \times J_{i}\right)\right) \backslash \overline{\Delta^{j i}}\end{cases}
$$

We have $\mathcal{D}_{0}^{j i} \in C^{1}\left(J_{j} \times J_{i}\right)$ except in the case $i=j \in I_{N} \backslash I_{0}$ for which there exists a curve $\Gamma^{j i}$ connecting $Y_{j}$ and $X_{i}$ with

$$
Y_{j}=\left(-\xi_{j}^{-}, 0\right) \quad \text { and } \quad X_{i}=\left(0, \xi_{i}^{+}\right)
$$

with $\Gamma^{j i}$ contained in $\left(J_{j}^{*} \times J_{i}^{*}\right) \cap \Delta^{j i}$. In this last case, we have $\mathcal{D}_{0}^{j i} \in C^{1}\left(\left(J_{j} \times J_{i}\right) \backslash\left(\Gamma^{j i} \cup\right.\right.$ $\left.\left\{Y_{j}, X_{i}\right\}\right)$ ). For all indices $i, j$, we have the following relation where $\mathcal{D}_{0}^{j i}$ is $C^{1}$ :

$$
\begin{equation*}
\left.\left.\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(y, x)=-H_{i}\left(\partial_{x} \mathcal{D}_{0}^{j i}\right)(y, x)\right)=-H_{j}\left(-\partial_{y} \mathcal{D}_{0}^{j i}\right)(y, x)\right) \tag{5.44}
\end{equation*}
$$

Moreover we have for all $x \in J_{i}$ with $x \neq \xi_{i}^{+}$if $j=i \in I_{N} \backslash I_{0}$

$$
\begin{equation*}
\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(0, x)=L_{0}(0)+K_{i}\left(\max \left(x, \xi_{i}^{+}\right)\right) \tag{5.45}
\end{equation*}
$$

and for all $y \in J_{j}$ with $y \neq-\xi_{j}^{-}$if $j=i \in I_{N} \backslash I_{0}$

$$
\begin{equation*}
\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(y, 0)=L_{0}(0)+K_{j}\left(-\max \left(y,-\xi_{j}^{-}\right)\right) \tag{5.46}
\end{equation*}
$$

We also have

$$
\begin{equation*}
\partial_{x} \mathcal{D}_{0}^{j i}(y, x)=L_{i}^{\prime}\left(\xi_{x}\right), \quad \partial_{y} \mathcal{D}_{0}^{j i}(y, x)=-L_{j}^{\prime}\left(\xi_{y}\right) \tag{5.47}
\end{equation*}
$$

for all $(y, x) \in \partial\left(J_{j} \times J_{i}\right)$ except for $i=j \in I_{N} \backslash I_{0}$ for which we exclude points $(y, x) \in$ $\left\{Y_{j}, X_{i}\right\}$.

Moreover for $j=i \in I_{0}$, we have

$$
\begin{equation*}
\xi_{x}=\xi_{y}=x-y \quad \text { for all } \quad(y, x) \in \partial\left(J_{j} \times J_{i}\right) \tag{5.48}
\end{equation*}
$$

and $j=i \in I_{N} \backslash I_{0}$, we have

$$
\left\{\begin{array}{ll}
\xi_{y}=x-y, & \xi_{x}=x-y  \tag{5.49}\\
\xi_{y}=\xi_{j}^{-}, & \xi_{x}=\xi_{i}^{+}
\end{array} \quad \text { for } \quad(y, x) \in\left(\partial\left(J_{j} \times J_{i}\right)\right) \cap \overline{\Delta^{j i}}\right.
$$

The results of this lemma are illustrated in Figures 2, 3, 4 and 5.
Proof of Lemma 5.11. We first treat the case $i=j$ and we then treat other cases.
Part I: cases $i=j$. We notice that $e(\tau, y, x)=e_{1}(\tau, y)+e_{2}(\tau, x)$ satisfies for $\tau \in(0,1)$ :

$$
e(\tau, y, x)=\tau L_{i}\left(-\frac{y}{\tau}\right)+(1-\tau) L_{i}\left(\frac{x}{1-\tau}\right) \geq L_{i}(x-y)
$$

where we have used the convexity of $L_{i}$. Therefore for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$ with $j=i$, we have

$$
\mathcal{D}_{\mathrm{jun-imp}}^{j i}(y, x)=\inf _{0<\tau<1} e(\tau, y, x) \geq L_{i}(x-y)
$$

Subcase I.1: $i=j \in I_{0}$. In this case we have $\mathcal{D}_{\text {jun }}^{j i}(y, x)=\mathcal{D}_{\text {jun-imp }}^{j i}(y, x)$, and then

$$
\mathcal{D}_{\mathrm{jun}}^{j i}(y, x) \geq L_{i}(x-y)=\mathcal{D}_{\mathrm{str}}^{j i}(y, x)=\mathcal{D}_{0}^{j i}(y, x)
$$

Figure 2: $(j, i)=(1,1)$

Figure 3: $i \neq j$ and $\left(i \in I_{0}\right.$ or $\left.j \in I_{0}\right)$

Figure 4: $(j, i)=(2,3)$ or $(i, j)=(3,2)$

Figure 5: $i=j \notin I_{0}$
for $(y, x) \in J_{j}^{*} \times J_{i}^{*}$ and then also for $(y, x) \in J_{j} \times J_{i}$, by continuity of the functions.
Subcase I.2: $i=j \in I_{N} \backslash I_{0}$. We proceed in several steps.
Step A: Proof of (5.43). We recall that in this case we have

$$
\mathcal{D}_{\text {jun }}^{j i}(y, x)= \begin{cases}\mathcal{D}_{\text {jun-imp }}^{j i}(y, x) & \text { for } \\ \mathcal{D}_{\text {jun-lin }}^{j i}(y, x) & \text { for } \quad(y, x) \in\left(J_{j} \times J_{i}\right) \backslash \Delta^{j i} \\ \Delta^{j i}\end{cases}
$$

and then

$$
\begin{align*}
\mathcal{D}_{0}^{j i}(y, x)=\min & \left(\mathcal{D}_{\text {jun }}^{j i}(y, x), \mathcal{D}_{\text {str }}^{j i}(y, x)\right) \\
& = \begin{cases}\mathcal{D}_{\mathrm{str}}^{j i}(y, x)=L_{i}(x-y) & \text { for } \quad(y, x) \in\left(J_{j} \times J_{i}\right) \backslash \Delta^{j i}, \\
\min \left(\mathcal{D}_{\text {jun-lin }}^{j i}(y, x), \mathcal{D}_{\text {str }}^{j i}(y, x)\right) & \text { for } \quad(y, x) \in \Delta^{j i} .\end{cases} \tag{5.50}
\end{align*}
$$

On the other hand, we have (a striclty convex function being above its tangent) for $x \neq \xi_{i}^{+}$,

$$
L_{i}(x)>L_{i}\left(\xi_{i}^{+}\right)+\left(x-\xi_{i}^{+}\right) L_{i}^{\prime}\left(\xi_{i}^{+}\right)=x L_{i}^{\prime}\left(\xi_{i}^{+}\right)+L_{0}(0)=\mathcal{D}_{\text {jun-lin }}^{j i}(0, x)
$$

and for $y \neq-\xi_{j}^{-}$

$$
L_{j}(-y)>L_{j}\left(\xi_{j}^{-}\right)+\left(-y-\xi_{j}^{-}\right) L_{j}^{\prime}\left(\xi_{j}^{-}\right)=-y L_{j}^{\prime}\left(\xi_{j}^{-}\right)+L_{0}(0)=\mathcal{D}_{\text {jun-lin }}^{j i}(y, 0)
$$

This shows that

$$
\begin{equation*}
\mathcal{D}_{\text {str }}^{j i}>\mathcal{D}_{\text {jun-lin }}^{j i} \quad \text { on } \quad\left(\partial\left(J_{j} \times J_{i}\right)\right) \cap \Delta^{j i} . \tag{5.51}
\end{equation*}
$$

We see that (5.50) and (5.51) imply (5.43).
Step B: description of $\left\{\mathcal{D}_{\text {jun-lin }}^{j i}=\mathcal{D}_{\text {str }}^{j i}\right\} \cap \Delta^{j i}$. Notice that

$$
\left\{\begin{array}{l}
\mathcal{D}_{\mathrm{jun}-\operatorname{lin}}^{j i}\left(0, \xi_{i}^{+}\right)=\xi_{i}^{+} L_{i}^{\prime}\left(\xi_{i}^{+}\right)+L_{0}(0)=L_{i}\left(\xi_{i}^{+}\right)=\mathcal{D}_{\mathrm{str}}^{j i}\left(0, \xi_{i}^{+}\right) \\
\mathcal{D}_{\mathrm{jun}-\operatorname{lin}}^{j i}\left(-\xi_{j}^{-}, 0\right)=\xi_{j}^{-} L_{j}^{\prime}\left(\xi_{j}^{-}\right)+L_{0}(0)=L_{j}\left(\xi_{j}^{-}\right)=\mathcal{D}_{\mathrm{str}}^{j i}\left(-\xi_{j}^{-}, 0\right)
\end{array}\right.
$$

This means that the functions $\mathcal{D}_{\text {jun }-\operatorname{lin}}^{j i}$ and $\mathcal{D}_{\text {str }}^{j i}$ coincide at the two points $X_{i}=\left(0, \xi_{i}^{+}\right)$ and $Y_{j}=\left(-\xi_{j}^{-}, 0\right)$. Therefore we have

$$
\left.\mathcal{D}_{\mathrm{str}}^{j i}<\mathcal{D}_{\mathrm{jun}-\operatorname{lin}}^{j i} \quad \text { on the open interval }\right] X_{i}, Y_{j}[
$$

because $\mathcal{D}_{\text {jun-lin }}^{j i}$ is linear and $\mathcal{D}_{\text {str }}^{j i}$ is strictly convex as a function of $y-x$.
The function $(y, x) \mapsto \mathcal{D}_{\text {str }}^{j i}(y, x)-\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)$ being convex because $\mathcal{D}_{\text {jun-lin }}^{j i}(y, x)$ is linear, we can consider the convex set

$$
K^{j i}=\left\{(y, x) \in J_{j} \times J_{i}, \quad \mathcal{D}_{\mathrm{str}}^{j i}(y, x) \leq \mathcal{D}_{\mathrm{jun}-\operatorname{lin}}^{j i}(y, x)\right\}
$$

Then for $i=j \in I_{N} \backslash I_{0}$, the set

$$
\Gamma^{j i}=\left\{(y, x) \in \Delta^{j i}, \quad \mathcal{D}_{\text {jun-lin }}^{j i}(y, x)=\mathcal{D}_{\text {str }}^{j i}(y, x)\right\}
$$

is contained in the boundary of the convex set $K^{j i}$. More precisely, we have

$$
\Gamma^{j i}=\left(\left(\partial K^{j i}\right) \cap \Delta^{j i}\right) \subset J_{j}^{*} \times J_{i}^{*}
$$

which shows that $\Gamma^{j i}$ is a curve and

$$
\overline{\Gamma^{j i}}=\Gamma^{j i} \cup\left\{X_{i}, Y_{j}\right\}
$$

Part II: Proof of (5.45), (5.46), (5.44), (5.47), (5.48) and (5.49). Using Proposition 5.7 for $\mathcal{D}_{\text {jun }}^{j i}$, Lemma 5.10 for $\mathcal{D}_{\text {str }}^{j i}$, and (5.28) for $\mathcal{D}_{\text {jun-lin }}^{j i}$ and the property (5.43), we get

$$
\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(0, x)= \begin{cases}L_{0}(0)+K_{i}\left(\max \left(x, \xi_{i}^{+}\right)\right) & \text {if } i \neq j \\
L_{0}(0)+K_{i}(x) & \text { if } i=j \in I_{0} \\
\left\{\begin{array}{lll}
L_{0}(0)+K_{i}(x) & \text { if } & x>\xi_{i}^{+} \\
L_{0}(0) & \text { if } & x<\xi_{i}^{+}
\end{array}\right. & \text {if } i=j \in I_{N} \backslash I_{0}\end{cases}
$$

which implies (5.45). Similarly we get
$\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(y, 0)= \begin{cases}L_{0}(0)+K_{j}\left(-\max \left(y,-\xi_{j}^{-}\right)\right) & \text {if } i \neq j \\ L_{0}(0)+K_{j}(-y) & \text { if } i=j \in I_{0} \\ \left\{\begin{array}{lll}L_{0}(0)+K_{j}(-y) & \text { if } & y>-\xi_{j}^{-} \\ L_{0}(0) & \text { if } y<-\xi_{j}^{-} & \text {if } i=j \in I_{N} \backslash I_{0}\end{array}\right.\end{cases}$
which implies (5.46). Relations (5.44) and (5.47) follow both from Proposition 5.7 and Lemma 5.10. Finally (5.48) and (5.49) follows from the previous results. This ends the proof of the lemma.
Lemma 5.12. (Boundary properties of $\mathcal{D}_{0}$ ) At any point $(y, x) \in\{0\} \times J_{i}$ with $x \neq \xi_{i}^{+}$ if $i \in I_{N} \backslash I_{0}$, we have for any $j \in I_{N}$

$$
\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(y, x) \quad=\left\{\begin{array}{rl}
-\max _{k \in I_{N}} H_{k}^{-}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right) & \text { if } \\
-H_{1}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right) & \text { if } \tag{5.52}
\end{array} \quad N=1\right.
$$

Similarly at any point $(y, x) \in J_{j} \times\{0\}$ with $y \neq-\xi_{j}^{-}$if $j \in I_{N} \backslash I_{0}$, we have for any $i \in I_{N}$

$$
\begin{equation*}
\left(\mathcal{D}_{0}^{j i}-x \partial_{x} \mathcal{D}_{0}^{j i}-y \partial_{y} \mathcal{D}_{0}^{j i}\right)(y, x)=-\max _{k \in I_{N}} H_{k}^{-}\left(\partial_{x} \mathcal{D}_{0}^{j k}(y, x)\right) \tag{5.53}
\end{equation*}
$$

Proof of Lemma 5.12. We first remark the general fact that

$$
H_{k}\left(L_{k}^{\prime}(\xi)\right)=H_{k}^{-}\left(L_{k}^{\prime}(\xi)\right) \quad \text { if } \quad \xi \leq 0
$$

i) Proof of (5.52). On the one hand, from Lemma 5.11, we have for points $(y, x) \in\{0\} \times J_{i}$ where $\mathcal{D}_{0}^{k i}$ is $C^{1}$

$$
-\left(\mathcal{D}_{0}^{k i}-x \partial_{x} \mathcal{D}_{0}^{k i}-y \partial_{y} \mathcal{D}_{0}^{k i}\right)(y, x)=H_{k}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right) \geq H_{k}^{-}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right)
$$

and this commom quantity is independent on $k$. Therefore to conclude to (5.52) in the case $N \geq 2$, it is enough to show that there exists at least an index $k$ such that

$$
\begin{equation*}
H_{k}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right)=H_{k}^{-}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right) . \tag{5.54}
\end{equation*}
$$

Case A: $N \geq 2$ and $k \neq i$. Then we have $\xi_{y} \leq 0$ and then

$$
H_{k}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right)=H_{k}\left(L_{k}^{\prime}\left(\xi_{y}\right)\right)=H_{k}^{-}\left(L_{k}^{\prime}\left(\xi_{y}\right)\right)=H_{k}^{-}\left(-\partial_{y} \mathcal{D}_{0}^{k i}(y, x)\right)
$$

Therefore (5.54) holds true for $k \neq i$.
Case B: $N=1$ and $k=i=1 \in I_{0}$. Then we have

$$
\mathcal{D}_{0}(y, x)=\mathcal{D}_{0}^{1,1}(y, x)=L_{1}(x-y)
$$

and by Lemma 5.10, we have for

$$
\left(\mathcal{D}_{0}^{11}-x \partial_{x} \mathcal{D}_{0}^{11}-y \partial_{y} \mathcal{D}_{0}^{11}\right)(y, x)=-H_{1}\left(-\partial_{y} \mathcal{D}_{0}^{11}(y, x)\right)
$$

which is in particular true for $y=0$. This shows (5.52) in the case $N=1$.
ii) Proof of (5.53). On the one hand, from Lemma 5.11, we have for points $(y, x) \in$ $J_{j} \times\{0\}$ where $\mathcal{D}_{0}^{j k}$ is $C^{1}$

$$
-\left(\mathcal{D}_{0}^{j k}-x \partial_{x} \mathcal{D}_{0}^{j k}-y \partial_{y} \mathcal{D}_{0}^{j k}\right)(y, x)=H_{k}\left(\partial_{x} \mathcal{D}_{0}^{j k}(y, x)\right) \geq H_{k}^{-}\left(\partial_{x} \mathcal{D}_{0}^{j k}(y, x)\right)
$$

and this commom quantity is independent on $k$. Therefore to conclude to (5.53), it is enough to show that there exists at least an index $k$ such that

$$
\begin{equation*}
H_{k}\left(\partial_{x} \mathcal{D}_{0}^{j k}(y, x)\right)=H_{k}^{-}\left(\partial_{x} \mathcal{D}_{0}^{j k}(y, x)\right) . \tag{5.55}
\end{equation*}
$$

Case A: $j \in I_{0}$. Then from Lemma 5.11, we have with $k=j$

$$
\begin{equation*}
\partial_{x} \mathcal{D}_{0}^{j k}(y, x)=L_{k}^{\prime}\left(\xi_{x}\right) \quad \text { with } \quad \xi_{x}=x-y \leq 0 \tag{5.56}
\end{equation*}
$$

Therefore (5.53) holds true for $k=j$.
Case B: $j \in I_{N} \backslash I_{0}$. We distinguish subcases.
Subcase B.1: $y>-\xi_{j}^{-}$. From Lemma 5.11, we still have (5.56) with $k=j$, which again implies (5.53) for $k=j$.
Subcase B.2: $y<-\xi_{j}^{-}$. Then we choose an index $k \in I_{0}$, and Lemma 5.11 implies that

$$
\partial_{x} \mathcal{D}_{0}^{j k}(y, x)=L_{k}^{\prime}\left(\xi_{x}\right) \quad \text { with } \quad \xi_{x}=\xi_{k}^{+}=0
$$

which again implies (5.53) for such $k \in I_{0}$. This ends the proof of the lemma.

We can now prove Theorem 5.1.
Proof of Theorem 5.1. From Lemma 5.11, we know that $\mathcal{D}_{0}$ has the regularity $C_{*}^{1}$ except on certain curves $\Gamma^{j i} \cup\left\{Y_{j}, X_{i}\right\}$ for $j=i \in I_{N} \backslash I_{0}$. So if $(y, x)$ is a point of local $C_{*}^{1}$ regularity of $\mathcal{D}_{0}$, then we simply set

$$
\varphi_{0}=\mathcal{D}_{0} \quad \text { locally around } \quad(y, x) .
$$

If $(y, x)$ is a point where $\mathcal{D}_{0}$ is not $C_{*}^{1}$, then we have $\mathcal{D}_{0}(y, x)=\mathcal{D}_{\text {jun }}(y, x)$, and we can simply set

$$
\varphi_{0}=\mathcal{D}_{\text {jun }} \quad \text { on } \quad J^{2} .
$$

The required equalities follow from Lemmas 5.11 and 5.12. Estimate (5.5) follows from the fact that $\mathcal{D}_{0}$ is the mimimum of $\mathcal{D}_{\text {jun }} \in C_{*}^{1}\left(J^{2}\right)$ and of functions in $C^{1}\left(J_{i}^{2}\right)$ for some $i$. This ends the proof of the theorem.

## 6 Application to the modeling of traffic flows

In this section we present the derivation of the Hamilton-Jacobi formulation of traffic on a junction. We also discuss the meaning of our junction condition in this framework and relate it to known results.

### 6.1 Primitive of the densities of cars

Figure 6: A divergent traffic junction
We consider a junction (represented on Figure 6) with a single incoming road (labeled by the index $i=1$ ) and $N-1 \geq 1$ outgoing roads (labeled by $i=2, \ldots, N$ ). This means that the cars move on the incoming road in the direction of the junction and then have to choose to go on one of the $N-1$ outgoing roads. We assume that the proportion of cars coming from the branch $i=1$ and going on each branch $j \in\{2, \ldots, N\}$ is a fixed number $\gamma_{j}>0$, with the obvious relation (for conservation of cars)

$$
\sum_{j=2, \ldots, N} \gamma_{j}=1
$$

We denote by $\rho^{i}(t, X) \geq 0$ the car density at time $t$ and at the position $X$ on the branch $i$. In particular, we assume that the traffic is described on each branch $i$ by a flux function $f^{i}: \mathbb{R} \rightarrow \mathbb{R}$. We assume that
each function $f^{i}$ is concave and has a unique maximum value at $\rho=\rho_{c}^{i}>0$.
The typical example of such flux function is given by the LWR model (Lighthill, Whitham [32] and Richards [36]), with

$$
\begin{equation*}
f(\rho)=\rho v(\rho) \quad \text { with the velocity } \quad v(\rho)=V_{\max }\left(1-\frac{\rho}{\rho_{\max }}\right) \tag{6.2}
\end{equation*}
$$

where $V_{\max }$ and $\rho_{\max }$ are respectively the maximal velocity and the maximal car density in the model). In this model the critical car density $\rho_{c}$ where $f$ is maximal, is equal to $\frac{1}{2} \rho_{\max }$.

We assume that the car densities are solutions of scalar conservation laws

$$
\left\{\begin{array}{l}
\rho_{t}^{1}+\left(f^{1}\left(\rho^{1}\right)\right)_{X}=0, \quad X<0,  \tag{6.3}\\
\rho_{t}^{j}+\left(f^{j}\left(\rho^{j}\right)\right)_{X}=0, \quad X>0, \quad \text { for } \quad j=2, \ldots, N
\end{array}\right.
$$

where we assume that the junction point is located at the origin $X=0$.
We do not make precise yet the junction condition at $X=0$, and we derive formally the Hamilton-Jacobi model of such a junction. For a function $g$ to be determined later on, let us consider the functions

$$
\left\{\begin{array}{ll}
U^{1}(t, X)=g(t)+\int_{0}^{X} \rho^{1}(t, Y) d Y, &  \tag{6.4}\\
U^{j}(t, X)=g(t)+\frac{1}{\gamma^{j}} \int_{0}^{X} \rho^{j}(t, Y) d Y, &
\end{array} \quad X>0, \quad \text { for } \quad j=2, \ldots, N . ~ .\right.
$$

Then we can compute formally for $j=2, \ldots, N$

$$
\begin{aligned}
U_{t}^{j} & =g^{\prime}(t)+\frac{1}{\gamma^{j}} \int_{0}^{X} \rho_{t}^{j}(t, Y) d Y \\
& =g^{\prime}(t)-\frac{1}{\gamma^{j}} \int_{0}^{X}\left(f^{j}\left(\rho^{j}(t, Y)\right)\right)_{X} d Y \\
& =-\frac{1}{\gamma^{j}} f^{j}\left(\rho^{j}(t, X)\right)+g^{\prime}(t)+\frac{1}{\gamma^{j}} f^{j}\left(\rho^{j}\left(t, 0^{+}\right)\right) .
\end{aligned}
$$

This shows that for $j=2, \ldots, N$

$$
\begin{equation*}
U_{t}^{j}+\frac{1}{\gamma^{j}} f^{j}\left(\gamma_{j} U_{X}^{j}\right)=h^{j}(t) \tag{6.5}
\end{equation*}
$$

where

$$
h^{j}(t):=g^{\prime}(t)+\frac{1}{\gamma^{j}} f^{j}\left(\rho^{j}\left(t, 0^{+}\right)\right)
$$

Remark that we can show similarly that (6.5) is still true for $j=1$ with

$$
h^{1}(t)=g^{\prime}(t)+f^{1}\left(\rho^{1}\left(t, 0^{-}\right)\right) .
$$

In particular, this shows that we can choose $g$ such that

$$
\begin{equation*}
g^{\prime}(t)=-f^{1}\left(\rho^{1}\left(t, 0^{-}\right)\right) \tag{6.6}
\end{equation*}
$$

then we have

$$
h^{i}(t) \equiv 0 \quad \text { for } \quad i=1, \ldots, N
$$

if and only if

$$
\begin{equation*}
f^{j}\left(\rho^{j}\left(t, 0^{+}\right)\right)=\gamma^{j} f^{1}\left(\rho^{1}\left(t, 0^{-}\right)\right) \quad \text { for } \quad j=2, \ldots, N \tag{6.7}
\end{equation*}
$$

which is exactly the expected condition which says that the proportion of incoming cars choosing to go on the branch $j \in\{2, \ldots, N\}$ is equal to $\gamma^{j}$.

Let us notice that if we choose the initial condition $g(0)=0$, then we deduce from (6.6) that

$$
-U^{1}(t, 0)=-g(t)=\int_{0}^{t} f^{1}\left(\rho^{1}\left(\tau, 0^{-}\right)\right) d \tau
$$

which shows that $-U^{1}(t, 0)$ can be interpreted as the total quantity of cars passing through the junction point $X=0$ during the time interval $[0, t)$. As a consequence, the quantity $-U_{t}^{1}(t, 0)$ can also be interpreted as the instantaneous flux of cars passing through the junction point.

Imagine for a moment, that we come back to a discrete description of the traffic, where each car of label $k$ has a position $x_{k}(t)$ with the ordering $x_{k}(t)<x_{k+1}(t)<0$. We can be interested in the label $k$ of the car $x_{k}(t) \leq 0$ which is the closest to the junction point $X=0$. Let us call it $K(t)$. We can normalize the initial data such that $K(0)=0$. Then the quantity of cars that have passed through the junction point $X=0$ during the time interval $[0, t)$ is equal to $-K(t)$, which is the exact discrete analogue of the continuous quantity $-U^{1}(t, 0)$.

On the other hand the number of cars between the positions $a=x_{A}(t)$ and $b=x_{B}(t)$ is obviously equal to $B-A$, and its continuous analogue is $\int_{a}^{b} \rho^{1}(t, X) d X=U^{1}(t, b)-U^{1}(t, a)$. This shows clearly that $U^{1}(t, X)$ can be interpreted as the exact continuous analogue of the discrete labeling of the cars moving in the traffic.

This interpretation can be pushed forward on the branches for $j \in\{2, \ldots, N\}$, where $U^{j}(t, X)$ is the continuous analogue of the discrete label of the cars that have decided to choose the branch $j$ and which is at time $t$ close to the position $X>0$.

### 6.2 Getting the Hamilton-Jacobi equations

We now set

$$
\left\{\begin{align*}
u^{1}(t, X)=-U^{1}(t,-X), & X>0,  \tag{6.8}\\
u^{j}(t, X)=-U^{j}(t, X), & \\
X>0, & \text { for } \quad j=2, \ldots, N
\end{align*}\right.
$$

and we define the convex Hamiltonian

$$
\left\{\begin{array}{l}
H_{1}(p)=-f^{1}(p)  \tag{6.9}\\
H_{j}(p)=-\frac{1}{\gamma^{j}} f^{j}\left(-\gamma^{j} p\right) \quad \text { for } \quad j=2, \ldots, N
\end{array}\right.
$$

Then we deduce from (6.5) that we have

$$
\begin{equation*}
u_{t}^{i}+H_{i}\left(u_{X}^{i}\right)=0, \quad X>0, \quad \text { for } \quad i=1, \ldots, N \tag{6.10}
\end{equation*}
$$

with equality of the functions at the origin, i.e.

$$
u^{i}(t, 0)=u(t, 0) \quad \text { for any } \quad i \in\{1, \ldots, N\} .
$$

Notice that for the choice $V_{\max }=1=\rho_{\max }$ in (6.2), we get with $f^{i}(\rho)=f(\rho)=\rho(1-\rho)$ for all $i \in I_{N}$, that

$$
L_{1}(q)=\frac{1}{4}(1+q)^{2} \quad \text { and } \quad L_{j}(q)=\frac{1}{\gamma^{j}} L_{1}(-q) \quad \text { for } \quad j=2, \ldots, N
$$

In particular this shows that the $L_{i}(0)$ are not all the same, even in the simplest case.

### 6.3 The junction condition and its interpretation

There is still a junction condition lacking to uniquely define the solution of (6.10). In view of Theorem 1.4, if we restrict our attention to continuous solutions $u$, then we will have $u \leq u_{o c}$ where $u_{o c}$ is the solution associated to the optimal control problem. This shows in particular that we have

$$
u(t, 0) \leq u_{o c}(t, 0)
$$

which means (in view of (6.8) and the interpretation of $-U^{1}$ given in Subsection 6.1) that we have a universal bound on the total amount of cars passing through the junction point during the time interval $[0, t)$. If we assume moreover that this amount of cars is maximal, then we can choose (and indeed have to choose) $u=u_{o c}$ and the natural junction condition is then

$$
\begin{equation*}
u_{t}(t, 0)+\max _{i=1, \ldots, N} H_{i}^{-}\left(u_{X}^{i}\left(t, 0^{+}\right)\right)=0 \tag{6.11}
\end{equation*}
$$

with

$$
H_{i}^{-}(p)=\sup _{q \leq 0}\left(p q-L_{i}(q)\right) \quad \text { and } \quad L_{i}(p)=\sup _{q \in \mathbb{R}}\left(p q-H_{i}(q)\right) .
$$

Using our assumption (6.1) on the functions $f^{i}$, let us define for $i=1, \ldots, N$ the Demand functions

$$
f_{D}^{i}(p)=\left\{\begin{array}{lll}
f^{i}(p) & \text { for } & p \leq \rho_{c}^{i} \\
f^{i}\left(\rho_{c}^{1}\right) & \text { for } & p \geq \rho_{c}^{i}
\end{array}\right.
$$

and the Supply functions

$$
f_{S}^{i}(p)= \begin{cases}f^{i}\left(\rho_{c}^{1}\right) & \text { for } \quad p \leq \rho_{c}^{i} \\ f^{i}(p) & \text { for } \quad p \geq \rho_{c}^{i}\end{cases}
$$

From assumption (6.1) on the functions $f^{i}$, we deduce that

$$
\left\{\begin{array}{l}
H_{1}^{-}(p)=-f_{D}^{1}(p), \\
H_{j}^{-}(p)=-\frac{1}{\gamma^{j}} f_{S}^{j}\left(-\gamma^{j} p\right), \quad \text { for } \quad j=2, \ldots, N .
\end{array}\right.
$$

Condition (6.11) means that

$$
\begin{align*}
-U_{t}^{1}(t, 0)=u_{t}(t, 0)=\min _{i=1, \ldots, N}- & H_{i}^{-}\left(u_{X}^{i}\left(t, 0^{+}\right)\right) \\
& =\min \left(f_{D}^{1}\left(\rho^{1}\left(t, 0^{-}\right)\right), \min _{j=2, \ldots, N} \frac{1}{\gamma^{j}} f_{S}^{j}\left(\rho^{j}\left(t, 0^{+}\right)\right)\right) . \tag{6.12}
\end{align*}
$$

Notice that from (6.7), it is natural to compare $f^{1}\left(\rho^{1}\left(t, 0^{-}\right)\right)$and $\frac{1}{\gamma^{j}} f^{j}\left(\rho^{j}\left(t, 0^{+}\right)\right)$. Then condition (6.12) is nothing else that the Demand and Supply condition of Lebacque, which claims that the passing flux is equal to the mimimum between the Demand and the Supply, as it is defined in [31].

This condition (6.12) is also equivalent to the condition defining the Riemmann solver at the junction point in the book of Garavello and Piccoli [24].
