## Abstract

A survey was carried out on the occurrence of dinitrocarbanilide (DNC) the marker residue for nicarbazin, in poultry produced in Ireland during the years 2002 to 2004. Liver (n = 736) and breast muscle samples (n = 342) were tested. DNC residues were found in 40% and 26% of liver and breast muscle samples at levels greater than 12.5 and 5  $\mu\text{g kg}^{-1}$ , respectively. DNC residues were found at  $>200 \mu\text{g kg}^{-1}$  in 12 and 0% of liver and muscle samples, respectively. Samples of breast muscle (n = 217) imported from 11 countries were also tested for DNC residues. A lower incidence of DNC residues (6%) was found in imported breast muscle. Egg samples (n = 546) were tested and DNC residues were found in nine samples, with levels ranging between 14 and 122  $\mu\text{g kg}^{-1}$ . Analysis of poultry, carried out as part of official food inspection in the period 2004 to 2006, indicated a reduction in the number of broiler liver samples containing DNC at  $>200 \mu\text{g kg}^{-1}$ , to approximately 7%. Low levels of DNC residues continue to be found in  $<2\%$  of egg samples.

## Introduction

Nicarbazin is an equimolar mixture of 4,4’-dinitrocarbanilide (DNC) and 2-hydroxy-4,6-dimethylpyrimidine (HDP). It is administered to poultry in feed for the prophylactic treatment of coccidiosis. Coccidiosis is an infectious disease caused by a microscopic protozoan parasite, which damages the intestinal tract of the bird, causing illness and sometimes death. Intensively

1 reared broilers are particularly susceptible to the disease, owing to the warm and humid conditions  
2 of broiler houses. The disease is not as common when birds are raised under extensive conditions.  
3 The licence for feed premixes containing nicarbazin as a single active ingredient was withdrawn  
4 under Commission Regulation 2205/2001/EC [Anon. 2001]. Nicarbazin continues to be legally  
5 marketed at levels of 40-50 mg kg<sup>-1</sup>, together with the feed additive ionophore narasin, as the  
6 combined product Maxiban® [Anon. 2007].

7 Nicarbazin is classified as a feed additive and not as a veterinary drug. No maximum  
8 residue limits (MRLs) have been set for nicarbazin in the European Union (EU). Nicarbazin  
9 depletion studies that have been carried out in broilers show that DNC is a more persistent residue  
10 than HDP in edible tissues (Porter and Gilfillan, 1955). The FAO/WHO Joint Expert Committee on  
11 Food Additives (JECFA) established an MRL of 200 µg kg<sup>-1</sup> for DNC, as the marker residue, in  
12 edible tissue (liver and meat) [Wells 1999]. The JECFA MRL for DNC has been adopted as the  
13 action limit by regulatory authorities in the Republic of Ireland and in the UK. Liver samples are  
14 tested for DNC residues in monitoring programmes on the island of Ireland as this tissue tends to  
15 contain higher residue concentrations than muscle. No MRL has been defined for DNC in eggs  
16 because nicarbazin is not approved for use in laying hens. An action level of 100 µg kg<sup>-1</sup> DNC in  
17 eggs has been adopted in the UK [Veterinary Residues Committee 2006].

18 The presence of DNC residues was first reported in poultry products nearly 20 years ago  
19 [De Giovanni et al. 1989, Oishi and Oda 1989]. Since then DNC residues have been reported in  
20 egg and liver samples tested in The Netherlands, UK, Italy and Ireland [Vertommen et al. 1989,  
21 Veterinary Residues Committee 2006, Gallo and Serpe 1997, O'Keeffe et al. 2005]. A number of  
22 studies have been carried out to identify the factors that may contribute to the presence of DNC  
23 residues in eggs and edible tissues, such as feed contamination [Cannavan and Kennedy 2000,  
24 Cannavan et al. 2000, McEvoy et al. 2003], withdrawal period [Cannavan and Kennedy 2000] and  
25 faecal recycling [Cannavan and Kennedy 2000, Penz et al. 1999]. The relationship between levels  
26 of nicarbazin in contaminated feed and corresponding levels of DNC residues in eggs and liver has  
27 proved useful in identifying trigger limits for nicarbazin as a contaminant in non-medicated feed.  
28 DNC residues in eggs can be attributed to poor practices at feedmills because nicarbazin is not  
29 licensed for use in laying hens. However, control of DNC residues in broiler tissues is more

1 complex than eggs because nicarbazin is widely applied to broilers and several on-farm factors  
2 that may contribute to residues. The contribution of on-farm factors to the DNC residues in broiler  
3 tissues has been described in more detail elsewhere [O’Keeffe et al 2006a].

4 In the study reported here, DNC contamination of tissues and eggs has been investigated  
5 in an integrated study across Ireland. Three surveys were organised to investigate the presence of  
6 DNC in eggs, liver and muscle between the years 2002 and 2004. In addition, a study on DNC  
7 residues in samples of imported poultry meat was undertaken.

## 8 9 **Experimental**

### 10 *Apparatus, chemicals and reagents*

11 4,4’-dinitrocarbanilide (DNC) standard material was from Sigma-Aldrich (St. Louis, MO, USA). The  
12 deuterium-labelled internal standard (d8-DNC) was custom synthesised by Quchem (Queen’s  
13 University, Belfast). Acetonitrile, methanol, dimethylformamide, water (all HiPerSolv grade),  
14 dimethylsulphoxide and *n*-hexane (Analar grade) were obtained from BDH (Merck, Poole, Dorset,  
15 UK). Cyclohexane (Pestican grade) was obtained from Labscan (Dublin, Ireland). DNC standard  
16 stock solution (1 mg ml<sup>-1</sup>) was prepared in dimethylsulphoxide (Biacore and HPLC assays) and  
17 DNC and d8-DNC standard stock solutions (1 mg ml<sup>-1</sup>) in dimethylacetamide (LC-MS/MS). The  
18 biosensor and HPLC standard solutions were prepared every 3 months and were stored in amber  
19 glass vials at room temperature in the dark preventing their solidification. LC-MS/MS standard  
20 solutions were stored at 4°C and were stable for at least one month. The optical SPR Biosensor  
21 system (Biacore™ Q) was obtained from Biacore™ (Uppsala, Sweden). Sensor chips (CM5), HBS-  
22 EP (0.01 M HEPES pH 7.4, 0.15 M NaCl, 3 mM EDTA, 0.005% v/v Surfactant P20) buffer and an  
23 amine coupling kit were purchased from Biacore™. Biacore control software, version 3.1, was used  
24 for instrument operation and BIA evaluation software, version 3.0, for data handling. Chip surfaces  
25 were prepared by immobilisation of a DNC mimic, glutamic acid (1-glutamic acid-(*p*-nitroanilide)),  
26 which was obtained from Sigma (Poole, Dorset, UK). A DNC polyclonal antibody (R555) was used  
27 for the biosensor assay. Production of the DNC antibody are described in detail elsewhere

1 [Connolly et al. 2002]. Bond Elut™ cartridges (C<sub>18</sub>, 500 mg, 3 ml) were from Varian (Harbor City,  
2 CA, USA).  
3

#### 4 *Biosensor screening assays*

5 Egg and liver samples were screened using a Biacore™ Biosensor assay [McCarney et al. 2003].  
6 The assay was modified from the published assay to allow the sensitive detection of DNC residues  
7 in muscle tissue.  
8

#### 9 *Egg and liver assays*

10 Homogenised egg or liver test samples (1 g) were weighed into 30 ml polypropylene tubes.  
11 Acetonitrile (4 ml) was added to samples and they were vortexed (10 sec) and sonicated (2 min)  
12 prior to centrifugation (1200×g, 10 min). The supernatants were transferred into glass test tubes  
13 and evaporated to dryness under a stream of nitrogen at 60°C. Sample extracts were allowed to  
14 cool for 1 min. At this point liver sample extracts were further purified. Liver extracts were  
15 reconstituted in cyclohexane (1 ml) by vortexing (15 sec). An aliquot (250 µl) of methanol/water  
16 (75:25, v/v) was added, the tubes were vortexed (10 sec) and placed in a water bath (37°C, 10  
17 min) prior to centrifugation (1200×g, 10 min). Aliquots (200 µl) of the aqueous layer were removed  
18 and evaporated to dryness under nitrogen.

19 Egg or liver sample extracts were subsequently reconstituted by sequentially adding  
20 methanol (200 µl) and HBS-EP buffer (800 µl), vortexing for 10 sec after each addition. Sample  
21 extracts were transferred to eppendorf tubes and centrifuged (14,000×g, 5 min). Sample extracts  
22 were further diluted 1:20 (v/v) in HBS-EP buffer prior to analysis on a Biacore™ Q system. Aliquots  
23 of the extracts (50 µl) were mixed with an equal volume of the antibody and injected for 2 min over  
24 the sensor chip surface at a flow rate of 25 µl min<sup>-1</sup>. The response for the sample was determined  
25 as the difference in the signal (Response Units, RU) measured before and after injection. The  
26 surface was regenerated with a 1 min pulse of dimethylformamide/180 mM sodium hydroxide  
27 (20:80, v/v) at a flow rate of 25 µl min<sup>-1</sup>.  
28

### 1 *Muscle assay*

2 A number of modifications of the DNC liver assay were made to allow the detection of low levels of  
3 DNC in muscle tissue. Muscle samples (5 g) were weighed into 30 ml polypropylene tubes and  
4 extracted with acetonitrile (5 ml). The supernatants were transferred into glass test tubes and  
5 evaporated to dryness under a stream of nitrogen at 60°C. Sample extracts were allowed to cool  
6 for 1 min. Muscle extracts were reconstituted by sequentially adding methanol (200 µl) and HBS-  
7 EP buffer (400 µl) and vortexing for 10 sec after each addition. Reconstituted extracts were further  
8 diluted (1:1, v/v) with HBS-EP buffer prior to analysis. In a deviation from the liver and egg assays,  
9 three additional steps were required to regenerate the chip surface. It was found during the  
10 development of the assay to detect low levels of DNC in muscle that there was noticeable carry  
11 over of electrostatic nicarbazin residues between injections and a more intensive chip regeneration  
12 protocol was required. Chip surfaces were allowed to contact sequentially with (a) 180 mM  
13 NaOH/acetonitrile (80:20, v/v), (b) 100 mM HCl/acetonitrile (80:20, v/v) and (c) 180 mM  
14 NaOH/acetonitrile (80:20, v/v) at a flow rate of 50 µl min<sup>-1</sup> for 60 sec.

### 15 *Chemical assays*

16 The presence of DNC residues were confirmed by LC-MS/MS [Yakkundi et al. 2001] or by HPLC-  
17 UV [Capurro et al. 2005].

### 18 *LC-MS/MS assays*

19 Homogenised liver samples (2.0 g) were weighed into 50 ml polypropylene centrifuge tubes.  
20 Internal standard (20 µl of the 10 µg ml<sup>-1</sup> d8-DNC working standard) was added to samples, which  
21 were mixed and allowed to stand for 15 min prior to extraction. Samples were homogenised in  
22 acetonitrile (8 ml) using a Silverson homogeniser for 40 sec and centrifuged (600×g, 10 min at  
23 4°C). An aliquot of the supernatant (2.5 ml) was transferred to glass tubes (10 ml) and evaporated  
24 to dryness under nitrogen at 60°C. After cooling, the residues were reconstituted in hexane (1 ml).  
25 This was extracted by vortexing (10 sec) with methanol/water (75:25 v/v, 250 µl). The tubes were  
26 centrifuged (600×g, 10 min at 4°C) and an aliquot (175 µl) of the aqueous layer was transferred to

1  
2 1 microvials for analysis. Calibration curve standard solutions containing DNC and d8-DNC in  
3  
4 2 methanol/water (75:25 v/v) were prepared at this time.  
5

6 3 A 25  $\mu\text{l}$  portion of the final sample extract was injected onto the LC-MS/MS system. The  
7  
8 4 LC-MS/MS system consisted of a Hewlett Packard (Stockport, Cheshire, UK) HPLC system,  
9  
10 5 comprising an 1100 Series binary pump, autosampler and solvent degasser, was coupled *via* an  
11  
12 6 electrospray interface to a Quattro LC (Micromass, Wythenshawe, UK), which operated in negative  
13  
14 7 ion mode. The  $[\text{M}-\text{H}]^-$  ion at  $m/z$  301 was monitored along with two transition ions at  $m/z$  137 and  
15  
16 8 107 for DNC and the  $[\text{M}-\text{H}]^-$  ion at  $m/z$  309 for the internal standard, d8-DNC. The LC column used  
17  
18 9 was a Luna 5  $\mu\text{m}$  C18 (2) 250  $\times$  4.6 mm (Phenomenex, Macclesfield, Cheshire, UK). The mobile  
19  
20 10 phase, which consisted of 0.05M ammonium acetate in acetonitrile/water (75:25 v/v), was pumped  
21  
22 11 at a rate of 1.0  $\text{ml min}^{-1}$ . The column effluent was split so that approximately 100  $\mu\text{l min}^{-1}$  entered  
23  
24 12 the mass spectrometer. The run time for each injection was 7 min.  
25  
26  
27  
28 13

#### 30 14 *HPLC assays*

31  
32 15 Homogenised egg, liver or muscle samples (2 g) were weighed into 30 ml polypropylene tubes.  
33  
34 16 Fortified egg and liver samples were prepared at levels of 25 and 250  $\mu\text{g kg}^{-1}$  by adding 50  $\mu\text{l}$   
35  
36 17 portions of 1 and 10  $\mu\text{g ml}^{-1}$  DNC standard solutions to negative control samples, respectively.  
37  
38 18 Fortified muscle samples were prepared at levels of 10 and 100  $\mu\text{g kg}^{-1}$  by adding 50  $\mu\text{l}$  portions of  
39  
40 19 0.4 and 4  $\mu\text{g ml}^{-1}$  DNC standard solutions to negative control samples, respectively. After  
41  
42 20 fortification, samples were allowed stand for 15 min prior to extraction. Acetonitrile (10 ml) were  
43  
44 21 added and samples were homogenised using a Polytron™. The homogeniser probe was washed  
45  
46 22 with acetonitrile (5 ml), which was retained. Samples were vortexed (2 min), sonicated (3 min) and  
47  
48 23 shaken (15 min), before centrifugation (1928 $\times g$ , 10 min, 4°C). The supernatant was transferred to  
49  
50 24 a clean polypropylene tube and the sample was re-extracted as before using the acetonitrile (5 ml)  
51  
52 25 previously used to wash the homogeniser probe, plus water (1 ml). The supernatants were  
53  
54 26 combined and defatted using hexane (2  $\times$  10 ml) by vortex mixing, centrifugation and removal of  
55  
56 27 the hexane layer. The acetonitrile layer was evaporated to dryness under nitrogen (60°C) and  
57  
58 28 reconstituted in acetonitrile/water (70:30, v/v, 500  $\mu\text{l}$ ). Samples extracts were passed through C<sub>18</sub>  
59  
60

1  
2 1 SPE cartridges (preconditioned with 2.5 ml acetonitrile and 2.5 ml acetonitrile/water (70:30, v/v))  
3  
4 2 and eluted with 2.5 ml acetonitrile/water (70:30, v/v). The eluate from the cartridge was collected in  
5  
6 3 a glass test-tube. Egg and liver extracts were evaporated to dryness under nitrogen (60°C) and  
7  
8 4 reconstituted in acetonitrile/water (80:20, v/v, 500 µl). Muscle samples were reconstituted in  
9  
10 5 acetonitrile/water (80:20, v/v, 200 µl). Extracts were allowed to sit for 15 min prior to transfer to  
11  
12 6 HPLC vials; a phase separation may occur in some samples and care was taken not to transfer  
13  
14 7 this lower oily layer into the HPLC vials.  
15  
16

17 8 A 25 µl portion of the final sample extract was injected onto the HPLC system. The HPLC  
18  
19 9 system consisted of a model 600 HPLC pump with a model 717 autosampler and model 484 UV  
20  
21 10 detector (set at 350 nm), all from Waters (Milford, MA, USA). The separation was carried out on a  
22  
23 11 stainless-steel analytical column (250 × 4.6 mm i.d) equipped with a Securiguard™ pre-column,  
24  
25 12 both packed with Hypersil BDS C<sub>18</sub> material (Phenomenex, Cheshire, UK). The column  
26  
27 13 temperature was maintained at 40°C. The mobile phase, consisting of water/acetonitrile (55:45,  
28  
29 14 v/v), was pumped at 1 ml/min. Under these conditions the retention time of DNC was  
30  
31 15 approximately 13 min. A Waters 746 data processing module was used for recording and  
32  
33 16 processing chromatograms.  
34  
35  
36  
37  
38

#### 39 18 *Calibration*

#### 40 19 41 20 42 21 43 22 44 23 *Biacore*

45 24 Standards were prepared by fortifying negative control egg and liver samples at concentrations of  
46  
47 25 0, 50, 100, 250, 500 and 1000 µg kg<sup>-1</sup> and muscle at concentrations of 0, 1, 2.5, 5, 10, 25 and 50  
48  
49 26 µg kg<sup>-1</sup> of DNC for calibration. Calibration curves were prepared by plotting response as a function  
50  
51 27 of DNC concentration (µg kg<sup>-1</sup>). The DNC concentration in test samples was read directly from the  
52  
53 28 calibration curve prepared from fortified samples that were run with that particular batch.  
54  
55 29  
56  
57  
58  
59  
60

## 1 *LC-MS/MS*

2  
3  
4 2 Calibration curve standard solutions containing DNC and d-8 DNC were prepared in  
5  
6 3 methanol/water (75:25 v/v). The DNC standards were prepared at the concentration 0, 100, 200,  
7  
8 4 300, 400 and 500  $\mu\text{g kg}^{-1}$  standard equivalent along with known equal amount of internal standard  
9  
10 5 d-8 DNC. The calibration curve was obtained by plotting the standard concentrations against the  
11  
12 6 peak area ratios of d-8 DNC and DNC. The DNC concentration in unknown samples was reported  
13  
14 7 as internal standard corrected value.  
15  
16  
17  
18 8

## 19 *HPLC*

20  
21  
22 10 Standards were prepared at concentrations of 0, 50, 100, 250, 500, 1000 and 2000  $\text{ng ml}^{-1}$  in  
23  
24 11 acetonitrile/water (80:20, v/v). Calibration curves were prepared by plotting peak area as a function  
25  
26 12 of DNC concentration ( $\text{ng ml}^{-1}$ ). The DNC concentration in test samples was determined from the  
27  
28 13 peak areas obtained for test sample extracts, as calculated from the calibration curve. The DNC  
29  
30 14 concentration in test samples was reported corrected for recovery using recovery factors  
31  
32 15 calculated from fortified samples that were run with that particular batch.  
33  
34  
35  
36 16

## 37 *Validation of methods*

38  
39  
40 18 The methods used in this comparison were validated according to current EU guidelines as  
41  
42 19 described in Commission Decision 2002/657/EC. The assays were validated to allow detection or  
43  
44 20 determination of DNC to an MRL of 200  $\mu\text{g kg}^{-1}$ . The sensitivity of the Biacore™ biosensor, HPLC-  
45  
46 21 UV and LC-MS/MS assays are much lower than the MRL. Limits of determination of DNC are 33.2,  
47  
48 22 12.5 and 10  $\mu\text{g kg}^{-1}$  in liver; 34.8, 12.5 and 10  $\mu\text{g kg}^{-1}$  in egg; and 5, 5 and 2  $\mu\text{g kg}^{-1}$  in muscle,  
49  
50  
51 23 respectively.  
52  
53  
54 24

## 55 *Industry surveys*

### 56 25 57 58 26 59 60 27 *Broiler liver survey*

1  
2 1 Liver samples (n = 736) were taken from 16 poultry companies (coded A to P), which were  
3  
4 2 representative of over 95% of domestic broiler production on the island of Ireland. In 2002,  
5  
6 3 samples were collected from companies A to H between March and November; no samples were  
7  
8 4 taken during May. The majority of the 238 samples were collected during the months of September  
9  
10 5 (n = 52), October (n = 89) and November (n = 81). In 2003, samples were collected from  
11  
12 6 companies A to H between February and November. The lowest and highest number of samples  
13  
14 7 were taken during the months of June (n = 7) and April (n = 46), respectively. Samples were  
15  
16 8 collected from companies I to P between May 2002 and April 2003. A total of 265 samples were  
17  
18 9 collected and the monthly sampling numbers are described in Figure 2. Samples were screened  
19  
20 10 using the immunobiosensor assay and samples found to contain DNC at levels greater than 33  $\mu\text{g}$   
21  
22 11  $\text{kg}^{-1}$  were selected for confirmatory analysis.  
23  
24  
25  
26  
27

### 28 13 *Broiler muscle survey*

29  
30 14 Breast meat samples (n = 342) were taken from 13 poultry companies. Three of the companies  
31  
32 15 involved in the liver survey (A, G and H) did not participate in this study. Samples were collected  
33  
34 16 from companies B to F (n = 127) between July and December 2003. A total of 215 samples were  
35  
36 17 collected from companies I to P between May 2003 and April 2004 at a frequency of 16 to 21  
37  
38 18 samples per month. Samples were screened using the immunobiosensor assay and samples  
39  
40 19 found to contain DNC at levels greater than 5  $\mu\text{g kg}^{-1}$  were selected for confirmatory analysis.  
41  
42  
43  
44  
45

### 46 21 *Egg survey*

47  
48 22 Egg samples (n = 546) were taken by official agriculture inspectors from egg packers,  
49  
50 23 representative of small, medium and large egg producers on the island of Ireland between 2003  
51  
52 24 and 2004. Samples were screened by the immunobiosensor assay and samples found to contain  
53  
54 25 DNC at levels greater than 12.5  $\mu\text{g kg}^{-1}$  were selected for confirmatory analysis. During sample  
55  
56 26 screening, it was found that the immunobiosensor could detect DNC residues in egg samples at  
57  
58 27  $<12.5 \mu\text{g kg}^{-1}$ .  
59  
60

28

### 1 Imported breast muscle survey

2 A survey of imported broiler breast muscle was undertaken in the period 2003 to 2004. In total, 217  
3 samples of imported breast muscle were obtained from retail outlets, from Environmental Health  
4 Officers carrying out inspections at food premises, by official agriculture inspectors at border  
5 inspection posts and meat processing companies. Samples were screened using the  
6 immunobiosensor assay and samples found to contain DNC at levels greater than  $5 \mu\text{g kg}^{-1}$  were  
7 selected for confirmatory analysis.

### 8 Confirmatory analyses

9 Samples from all surveys screened as containing DNC residues were confirmed by an  
10 independent chemical assay (HPLC-UV or LC-MS/MS). HPLC-UV has been described as suitable  
11 for confirming the presence of Group B substances, when used in conjunction with a second  
12 independent detection assay (Anon. 2002). In this survey, an immunobiosensor was used as the  
13 second independent detection assay.

## 14 Results and discussion

### 15 Liver survey

16 An overall summary of the poultry liver survey is presented in Figure 1. The survey showed that 12  
17 and 3% of samples contained DNC residues at  $>200$  and  $>1000 \mu\text{g kg}^{-1}$ , respectively. DNC  
18 residues were found at  $<200 \mu\text{g kg}^{-1}$  in 28% of samples and no residues were detectable (i.e. not  
19 detected above  $33 \mu\text{g kg}^{-1}$  by immunobiosensor and/or confirmed above  $12.5 \mu\text{g kg}^{-1}$  using  
20 chemical assays) in 60% of samples.

### 21 Seasonal variation in levels of DNC in liver

22 The seasonal variation in DNC levels in broiler liver samples from eight companies (I to P) is  
23 shown in Figure 2. In general, there was a similarity in the proportion of samples containing DNC  
24 and of samples containing DNC at  $>200 \mu\text{g kg}^{-1}$  over time. In the period June to August the  
25 incidence of DNC containing liver samples was lower by a factor of at least twofold compared to

1  
2 1 other months. A number of hypotheses may be proposed for the lower incidence of DNC residues  
3  
4 2 in poultry during the June to August period. One hypothesis is that reduced usage of nicarbazin  
5  
6 3 may have occurred during the summer months; nicarbazin can cause heat stress, resulting in  
7  
8 4 increased mortality in broilers during warm weather. A second hypothesis is that the lower  
9  
10 5 incidence of DNC residues may be related to the removal of licensing for products containing  
11  
12 6 nicarbazin alone that occurred in May 2002. A third hypothesis is that the higher incidence of DNC  
13  
14 7 residues in broiler liver from September onwards may have been due to changes in the feeding  
15  
16 8 programmes used on poultry farms, with nicarbazin-containing feed being given to birds closer to  
17  
18 9 slaughter time.  
19  
20  
21  
22  
23

#### 24 11 *Variation in DNC levels in liver sampled from different companies*

25  
26  
27 12 The breakdown by company of samples containing DNC residues and containing DNC residues  
28  
29 13  $>200 \mu\text{g kg}^{-1}$  is shown in Table I. For two companies (F and G) no samples containing DNC  
30  
31 14 residues were found; however, few samples were sourced from these companies during the  
32  
33 15 survey. The percentages of samples containing DNC residues range between 15 and 84% for the  
34  
35 16 other companies. The mean value for 16 companies was 42% of samples contained DNC  
36  
37 17 residues. The mean result for companies containing DNC residues  $>200 \mu\text{g kg}^{-1}$  was 14%, with the  
38  
39 18 lowest at 0% and the highest at 42%. Three companies, C, E and L had 10, 22 and 33% of  
40  
41 19 samples containing DNC residues but 0, 0 and 1% of samples from these companies contained  
42  
43 20 DNC residues  $>200 \mu\text{g kg}^{-1}$ , respectively. Companies M and N had less than 10% of samples  
44  
45 21 containing DNC  $>200 \mu\text{g kg}^{-1}$ .  
46  
47  
48  
49  
50

#### 51 23 *Survey of breast meat*

52  
53 24 A total of 342 samples of broiler breast meat (muscle) were tested for DNC residues. The overall  
54  
55 25 breakdown of results is shown in Figure 3. DNC residues were determined in 26% of samples at  
56  
57 26 levels ranging between 5 and  $183 \mu\text{g kg}^{-1}$ . No residues were detected in 74% of muscle samples.  
58  
59 27 No muscle sample contained DNC residues above  $200 \mu\text{g kg}^{-1}$ . A lower percentage of muscle  
60  
28 samples contained measurable DNC residues compared to liver samples. A lower incidence of

1  
2 1 DNC-positive muscle, compared with liver, is supported by the pharmacokinetic profiles, which  
3  
4 2 show that DNC residues occur at higher concentrations in liver compared to muscle [Anon. 1999].  
5  
6 3 As a result, DNC residues may be detected for a longer period of time in liver and the probability of  
7  
8 4 finding DNC residues in tissue is lower for muscle than for liver. The results for the muscle and  
9  
10 5 liver surveys indicate that liver is the most appropriate matrix to use for monitoring DNC residues  
11  
12 6 because it is the matrix in which residues persist at highest concentrations.  
13  
14  
15 7

#### 17 8 *Seasonal variation in levels of DNC in muscle*

19  
20 9 The seasonal variation for DNC residues in breast meat is shown in Figure 4. The average monthly  
21  
22 10 incidence of muscle samples containing DNC is 20%. The highest incidence occurred in the  
23  
24 11 months of May, November and March with 28, 28 and 42% of muscle samples containing DNC  
25  
26 12 residues, respectively. The proportion of liver samples likely to contain DNC at levels  $>200 \mu\text{g kg}^{-1}$   
27  
28 13 was estimated from the muscle survey results. A level of approximately  $7 \mu\text{g kg}^{-1}$  DNC in muscle  
29  
30 14 has been estimated as equivalent to approximately  $200 \mu\text{g kg}^{-1}$  in liver tissue. This approximation  
31  
32 15 is derived from the mean values obtained for a comparison of DNC residues in liver and muscle for  
33  
34 16 birds raised in deep litter ( $9.0 \mu\text{g kg}^{-1}$  muscle  $\approx 200 \mu\text{g kg}^{-1}$  liver) and those on wire flooring ( $5.5 \mu\text{g}$   
35  
36 17  $\text{kg}^{-1}$  muscle  $\approx 200 \mu\text{g kg}^{-1}$  liver) [Cannavan and Kennedy 2000]. Using this estimation, the  
37  
38 18 percentage of liver samples likely to contain DNC at  $>200 \mu\text{g kg}^{-1}$  was calculated (Figure 4); the  
39  
40 19 estimated incidence of liver samples containing  $>200 \mu\text{g kg}^{-1}$  DNC was similar to that observed for  
41  
42 20 the liver survey, with a mean value of 14% (Table I).  
43  
44  
45  
46 21

#### 48 22 *Variation in DNC levels in muscle sampled from different companies*

50  
51 23 The breakdown by company of muscle samples containing DNC residues and corresponding liver  
52  
53 24 samples (estimated as containing DNC residues  $>200 \mu\text{g kg}^{-1}$ ) is shown in Table I. No samples  
54  
55 25 from companies E and F contained measurable DNC residues and company C had only 3% of  
56  
57 26 samples containing measurable DNC residues. For the other companies, the proportion of muscle  
58  
59 27 samples containing measurable DNC ranged between 20 and 50%. A comparison between the  
60  
28 liver survey (2002/03) and estimated liver survey (2003/04) shows that for some companies (B, I,

1  
2 1 J, L and M) there was a higher incidence of DNC residues at  $>200 \mu\text{g kg}^{-1}$  in the second survey,  
3  
4 2 while for companies K, N, O and P however a lower incidence in liver may be concluded from the  
5  
6 3 muscle survey (Table I). Companies C and D showed no appreciable change in incidence between  
7  
8 4 the two surveys.  
9

10  
11 5 The proportion of liver samples containing DNC residues  $>200 \mu\text{g kg}^{-1}$  (determined for  
12  
13 6 2002/03 and estimated for 2003/04) may vary between companies and within companies from year  
14  
15 7 to year. The results of the surveys show that DNC residues in broilers occur throughout the year  
16  
17 8 and that flocks require frequent sampling (such as each month), proportional to scale of  
18  
19 9 production, to identify the situation.  
20

#### 21 22 10 23 24 11 *Imported breast muscle*

25  
26 12 A total of 217 samples of imported breast meat were sampled over the period May 2003 to  
27  
28 13 September 2004. The objective of the survey was to make a comparison between DNC residues in  
29  
30 14 domestic and imported poultry meat consumed on the island of Ireland. The results of the survey  
31  
32 15 are shown in Table II. Samples were sourced from wholesalers, meat processing companies,  
33  
34 16 border inspection posts and retail outlets. The imported breast meat samples originated from 11  
35  
36 17 different countries. DNC residues were determined in 13 samples at levels ranging from 2.7 to 18.7  
37  
38 18  $\mu\text{g kg}^{-1}$ . The results of the survey indicate that DNC residues were at a lower level in imported  
39  
40 19 meat (6%) compared to domestic meat samples (26%). Samples from only three countries had  
41  
42 20 measurable DNC residues (France, Thailand and The Netherlands). The relatively low number of  
43  
44 21 positives for DNC in imported meat suggests (a) that alternative anticoccidial agents may be used  
45  
46 22 in other countries and/or (b) practices are adopted at feed mills and on farms that allow better  
47  
48 23 control of DNC residues in poultry production.  
49  
50

#### 51 52 24 53 54 25 *Survey of eggs*

55  
56  
57 26 A survey of table eggs was carried out during 2003 to 2004. A total of 546 egg samples were  
58  
59 27 collected and DNC residues were determined in nine samples. No residues were detectable (i.e.  
60  
28 not detected above  $34.8 \mu\text{g kg}^{-1}$  by immunobiosensor and/or confirmed above  $12.5 \mu\text{g kg}^{-1}$  using

1  
2 1 chemical assays) in 98% of egg samples. The levels of DNC residues present ranged between 14  
3  
4 2 and 122  $\mu\text{g kg}^{-1}$ . DNC residues occurred in egg samples throughout the year. The contaminated  
5  
6 3 egg samples were sourced from four companies and one of these companies had five positive  
7  
8 4 samples. Nicarbazine is not approved for the treatment of layer hens and residues in eggs may be  
9  
10 5 attributed to contamination of layer feed with low levels of nicarbazine [Cannavan et al. 2000]. DNC  
11  
12 6 residues may be eliminated from eggs through adequate quality control of feed samples shipped to  
13  
14 7 farms.  
15  
16  
17 8

#### 9 *Performance of the biosensor screening assay for detection of nicarbazine residues*

10  
11 Connolly et al. (2003) characterised the antibody applied in this assay. The antibody was shown to  
12  
13 be specific towards DNC and did not cross-react to other potential interfering substances namely,  
14  
15 the anti-coccidials, toltrazuril, halofuginone and ronidazole. In routine application, it has been found  
16  
17 that the antibody does not cross-react to lasalocid and other ionophore (monensin, salinomycin  
18  
19 and narasin) residues detected in egg and liver samples. The cut-offs for sending samples for  
20  
21 confirmatory analysis was determined through the analysis of 20 negative liver and 20 known  
22  
23 negative egg samples. Briefly, analysis of 20 known negative livers yielded values of  $1.19 \pm 5.32$   
24  
25  $\mu\text{g kg}^{-1}$ . The limits of detection (mean + 3 S.D.) and determination (mean + 6 S.D.) were calculated  
26  
27 as 17.1 and 33.2  $\mu\text{g kg}^{-1}$ , respectively. A second validation study was carried out in eggs and  
28  
29 analysis of 20 known negative eggs yielded values of  $3.07 \pm 5.29 \mu\text{g kg}^{-1}$ . The limits of detection  
30  
31 and determination were calculated as 18.9 and 34.8  $\mu\text{g kg}^{-1}$ , respectively. A more comprehensive  
32  
33 evaluation of the suitability of the limits of determination was carried out during the egg and liver  
34  
35 surveys. A total of 145 samples confirmed to contain DNC residues by HPLC were also screened  
36  
37 by immunobiosensor. Evaluation of the results indicated that false negatives rates for the assay  
38  
39 are generally <5%. In the concentration ranges >33 - 100 (n = 42 samples), >100 - 200 (n = 62),  
40  
41 and >200  $\mu\text{g kg}^{-1}$  (n = 41); 2, 1 and 0 false negative results were observed, respectively. This  
42  
43 corresponded to false negative rates of <5, <2 and 0%, respectively. It is highlighted that no false  
44  
45 negative results were observed at or around the MRL.  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

#### 29 *Comparison of results from official food inspection*

1  
2 1 The results for DNC residues in poultry liver and eggs samples between 2002 and 2005 indicate  
3  
4 2 that the percentage of liver samples containing DNC at levels  $\geq 200 \mu\text{g}/\text{kg}$  decreased to 7% in 2005  
5  
6 3 (O’Keeffe et al. 2005; O’Keeffe et al. 2006). This was a 50% reduction in positives from the  
7  
8 4 previous three years even though the useage of Maxiban throughout Ireland had increased. The  
9  
10 5 results of official food inspection for 2006 will provide a clearer indication if this reduction in DNC  
11  
12 6 positives is sustainable or just a brief improvement. The reduction in DNC positives can be largely  
13  
14 7 attributed to on-farm investigations, which were carried out with the aim of identifying the cause of  
15  
16 8 DNC residues during 2004 to 2005 (O’Keeffe et al. 2007). In addition, there has been increased  
17  
18 9 scrutiny placed on the control of DNC residues by regulatory agencies. As a result, a number of  
19  
20 10 companies have instigated their own testing programs, which are aimed at fulfilling self-monitoring  
21  
22 11 criteria. The results for egg testing between 2002 and 2005 indicate that the percentage of DNC  
23  
24 12 positives in eggs remains static at approximately 1.5%.  
25  
26  
27  
28  
29

## 30 14 31 15 **Conclusions**

32  
33  
34 16 DNC is a frequent contaminant of poultry products on the island of Ireland and has been shown to  
35  
36 17 be a contaminant both of liver and breast meat. Residues may also occur in eggs but are typically  
37  
38 18 at less than 2% of samples. Residues in eggs may be largely attributed to contaminated feed  
39  
40 19 because administration of nicarbazin to layers is not approved because it affects bird fertility and  
41  
42 20 egg shells. DNC residues occur in poultry samples throughout the year, indicating that this  
43  
44 21 anticoccidial needs to be monitored continuously in poultry. Residues in liver and meat can be  
45  
46 22 caused by a number of different factors, but may be attributed mainly as due to improper feed  
47  
48 23 management on farms and at feed mills (O’Keeffe et al. 2007). The number of liver samples  
49  
50 24 exceeding the MRL of  $200 \mu\text{g kg}^{-1}$  DNC may vary considerably within individual companies  
51  
52 25 between years. In 2005, there was a reduction in the number of broiler liver samples containing  
53  
54 26 DNC at  $>200 \mu\text{g kg}^{-1}$ , to approximately 7% of samples tested in the monitoring programmes  
55  
56 27 (O’Keeffe et al. 2006, Shortt 2006). The available results from official food inspections for 2006  
57  
58 28 indicate a similar lower proportion of samples containing DNC residues at levels  $>200 \mu\text{g kg}^{-1}$ . The  
59  
60 29 reduction in DNC positives may be attributed partly to on-farm investigations, which were carried

1  
2 1 out during 2004/05 with the aim of identifying the causes for DNC residues in poultry (O'Keeffe et  
3  
4 2 al. 2007). In addition, there has been increased scrutiny on the control of DNC residues in poultry  
5  
6 3 by regulatory authorities and a number of companies have instigated there own testing  
7  
8 4 programmes to fulfil self-monitoring as required by EU food law (96/23/EC).  
9

Table I Variation in the percentage of liver and muscle samples containing DNC residues that were surveyed from companies A to P

Company	Liver Survey (n = 736)		Domestic Muscle Survey (n = 342)	
	Samples containing DNC $\geq 12.5 \mu\text{g kg}^{-1}$ (%)	Samples containing DNC $\geq 200 \mu\text{g kg}^{-1}$ (%)	Samples containing DNC $\geq 5 \mu\text{g kg}^{-1}$ (%)	Estimate of liver samples containing DNC $\geq 200 \mu\text{g kg}^{-1}$ (%)
A	84	26	-	-
B	47	16	38	29
C	15	1	3	0
D	41	13	36	14
E	22	0	0	0
F	0	0	0	0
G	0	0	-	-
H	40	33	-	-
I	46	11	36	17
J	67	25	30	33
K	83	25	22	9
L	33	0	27	25
M	25	6	20	17
N	44	8	20	3
O	63	42	50	29
P	59	16	20	8
Mean	42	14	23	14

Table II *The incidence of DNC residues in breast muscle samples imported into the island of Ireland*

Country	Number of samples tested	Number of samples containing DNC at >5 µg/kg
The Netherlands	68	4
Denmark	26	0
Belgium	7	0
France	10	8
Brazil	58	0
Chile	2	0
Germany	14	0
Thailand	22	1
Romania	5	0
New Zealand	4	0
UK	1	0
