Agaritine content of 53 *Agaricus* species collected from nature

Abstract

Fifty-three different species of the genus *Agaricus* were collected in the Czech Republic during the period 1998-2001 and identified by an experienced mycologist. The samples were analysed for agaritine (N^2 -(γ -L-glutamyl)-4-hydroxymethylphenylhydrazine) content, a precursor to a suspected rodent carcinogen. There was a huge variation in agaritine content between species, less variation between samples of a species. Whereas the cultivated mushroom *Agaricus bisporus* commonly contain 200-500 mg agaritine/kg fresh weight, no less than 24 of the 53 species contained agaritine levels above 1000 mg/kg fresh weight. The highest level was found in *A. elvensis* containing up to 10,000 mg/kg fresh weight. Seventeen species contained intermediate levels (125-1000 mg/kg), and twelve species below 125 mg/kg. Some of the species producing low levels of agaritine might be candidates for future strain-development of *Agaricus* mushrooms for cultivation. No correlation could be observed between the agaritine content and size of the mushroom, week of the year when collected, year of collection, or site of collection. Besides occurring in the genus *Agaricus*, some species of the genera *Leucoagaricus* and *Macrolepiota* were also shown to contain agaritine.

Introduction

The commonly eaten cultivated mushroom, *Agaricus bisporus*, belongs to the *Agaricaceae* family. For a long time *A. bisporus* was believed to have been derived from several different wild *Agaricus* species (Toth 2000), and its continued propagation over many centuries to have resulted in several commercial strains which have no exact counterpart in nature. This hypothesis has now been proven incorrect as wild *A. bisporus* populations

1
2 have been identified in various parts of the world (Mozina et al. 1993; Kerrigan 1995). In
3
4 some countries, strains of other species, such as *A. bitorquis*, are the preferred cultivated
5
6 varieties (Schulzová et al. 2002).
7
8
9

10
11 In 1961 Levenberg isolated a characteristic glutamine-containing compound from the
12
13 press-juice of *A. bisporus*. He characterised the compound physically and elucidated its
14
15 chemical structure as N²-(γ -L-glutamyl)-4-hydroxymethylphenylhydrazine (Figure 1), and
16
17 gave it the trivial name agaritine. As shown in Table I, the level of agaritine in the
18
19 cultivated mushroom is fairly high, usually in the range 200 to 500 mg/kg fresh weight
20
21 (Andersson and Gry 2004), but levels as high as 1700 mg/kg fresh weight have been
22
23 reported (Liu et al. 1982).
24
25
26
27
28
29
30

31 [Fig. 1 inserted about here]

32 [Table I inserted about here]

33
34
35
36
37
38 Agaritine is the predominant, although not the only phenylhydrazine derivative in *A.*
39
40 *bisporus*. The compounds 4-carboxyphenylhydrazine, N²-(γ -L-glutamyl)-4-carboxy-
41
42 phenylhydrazine, and 4-hydroxymethylbenzenediazonium ion make up around 10% of the
43
44 total phenylhydrazines in the mushroom (Levenberg 1962; Chauhan et al. 1984, 1985; Ross
45
46 et al. 1982).
47
48
49
50
51
52

53 The potential carcinogenicity of *A. bisporus*, and the possible role of agaritine and the other
54
55 phenylhydrazine derivatives in inducing this severe adverse effect, has been a matter of
56
57 controversy for a number of years (Gry and Pilegaard 1991; Gry and Andersson 1998; Toth
58
59
60

1
2 2000; Andersson and Gry 2004). In long-term *in vivo* studies, a diet of fresh or baked *A.*
3
4 *bisporus* for 3 days per week over 2 years produced tumours in various tissues of both male
5
6 and female outbred Swiss mice (Toth and Ericsson 1986; Toth et al. 1997a). An elevated
7
8 tumour incidence, although not statistically significant, was observed when baked
9
10 mushrooms were fed to mice according to a more balanced feeding schedule - 12 hours
11
12 each day for 5 days each week during life-time (Toth et al. 1997b). Similarly, oral
13
14 administration of 4-carboxyphenylhydrazine or N²-(γ -L-glutamyl)-4-
15
16 carboxyphenylhydrazine, or the 4-hydroxymethylbenzenediazonium ion resulted in tumour
17
18 induction in Swiss mice (Toth 2000). The main phenylhydrazine in the mushroom,
19
20 agaritine (98% pure), however, did not result in tumour induction when administered in
21
22 drinking water in a long-term carcinogenicity study (Toth et al. 1981). This observation is
23
24 unexpected, as agaritine has been shown to bind covalently to mouse DNA (Shephard and
25
26 Schlatter 1998) and to increase the mutation frequency in forestomach and kidney tissue of
27
28 lacI transgenic mice *in vivo* (Shephard et al. 1995). As it was recently shown that agaritine
29
30 is unstable in oxygenated aqueous solution (Hajslova et al. 2002), it cannot be ruled out
31
32 that the exposure to agaritine was lower than expected in the long-term carcinogenicity
33
34 experiment.
35
36
37
38
39
40
41
42
43
44
45

46 Until it has been established whether consumption of the cultivated mushroom constitutes
47
48 a risk for adverse health effects or not, it seems advisable to abstain from exaggerated
49
50 exposures to phenylhydrazine derivatives (Schulzová et al. 2002). This could be done by
51
52 growers substituting the strains of the cultivated mushroom producing high levels of
53
54 agaritine with strains or other *Agaricus* species having comparable organoleptic properties
55
56 but producing lower levels of agaritine. Sources for such strains may be available from the
57
58
59
60

1
2 nature. The present study reports on the quantity of agaritine detected in 53 different
3
4 *Agaricus* species collected in the Czech Republic. The data may also be of interest for
5
6 mushroom pickers when assessing the edibility of *Agaricus* species to be collected.
7
8
9

10 11 12 13 14 **Materials and Methods**

15 16 *Samples and chemicals*

17
18 Different *Agaricus* species were picked at various locations in the Czech Republic (most of
19 them in the central part of Bohemia, close to Prague) during the mushroom growing
20 seasons 1998-2001. All species were determined by one of the authors (Jiri Hlaváček), an
21 experienced mycologist specialized on the taxonomy of the genus *Agaricus*. The *Agaricus*
22 taxonomy remains far from clear, despite the contributions of many authors over the years,
23 especially Pilát (1951), Möller (1952), Essette (1964), Heinemann (1977), Wasser (1980),
24 Cappelli (1984), Knudsen (1992), Bohus (1995), Nauta (2001) and Parra (2003). As a
25 consequence, mycologists advocate different schools of *Agaricus* taxonomy. We have
26 chosen the practical approach of presenting both the taxonomic names as given by the
27 mycologist who determined the mushroom species, J. Hlaváček, who used more narrow
28 concepts identifying a species, and the taxonomic names commonly used in the Western
29 and Northern European countries where broader concepts identifying the various *Agaricus*
30 species are prevailing (Knudsen 1992; Nauta 2001).
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50

51
52 Most mushroom samples delivered to the Institute of Chemical Technology (Prague) for
53 chemical analysis of agaritine content were clearly identified and did not require further
54
55 consultation. In a few cases where the delivered samples were not adequately identified,
56
57
58
59
60

1
2 Hlaváček was consulted again. As he unfortunately died during the present study, his
3
4 colleagues Borovička and Burel took over the confirmation step of a few samples.
5
6
7

8
9 Mushrooms were stored in the refrigerator until analysed (Schulzová et al. 2002), which
10
11 generally was within three days from being collected. We recently showed that the
12
13 agaritine content of cultivated *Agaricus* purchased on the open market remained
14
15 unchanged for the first three days in the refrigerator (5°C), after which the agaritine content
16
17 started to decrease (Schulzová et al. 2002).
18
19
20
21

22
23 Water used for preparation of solutions was distilled and further purified using the Milli Q
24
25 RG purification system (Millipore, Germany). Methanol used for extraction was supplied
26
27 by Penta (Chrudim, Czech Republic), and gradient grade methanol for the HPLC mobile
28
29 phase was purchased from Merck (Darmstadt, Germany). The agaritine standard was
30
31 synthesised by Henrik Frandsen, Institute of Food and Veterinary Research, according to
32
33 the method of Wallcave et al. (1979), but with some important modifications being
34
35 introduced (Frandsen 1998). The synthesised agaritine was more than 85% pure as shown
36
37 at wavelength 200, 237 and 280 nm by high performance liquid chromatography (HPLC).
38
39 The purity factor of the agaritine peak reported by the Hewlett Packard ChemStation peak
40
41 purity software was 999.9. The main impurity (11.9-13.6%) in the standard originated from
42
43 the agaritine synthesis and was stable during the experiments reported here. The standard
44
45 was protected from light and stored under oxygen-free nitrogen in the freezer.

50
51
52
53
54

55 ***Sample preparation***

56
57 Agaritine standard for identification: a stock solution of agaritine in methanol (0.25 mg/ml)
58
59
60

1
2 was prepared. From this 100 μ l were transferred into vials and evaporated to dryness by a
3
4 stream of oxygen-free nitrogen. The vials were stored sealed in the freezer. Stability tests
5
6 showed the dry agaritine standard in the freezer to be stable (Schulzová et al. 2002). Before
7
8 analysis, the agaritine standard was dissolved in 1 ml of Milli Q water and analysed within
9
10 6 hours (Schulzová et al. 2003).
11
12

13
14
15
16 Approximately 20 gram of fresh whole mushroom was mixed with 100 ml methanol and
17
18 homogenised for 10 minutes in an Ultra Turax (Janke a Kunkel, IKA-Werk). The
19
20 homogenate was shaken for 30 minutes and a crude extract prepared by filtration. The
21
22 volume of the filtrate was adjusted to 200 ml with methanol, 10 ml of the extract was
23
24 evaporated to dryness and the residue dissolved in 2 ml Milli Q water. This solution was
25
26 filtered through a microfilter (25 mm Filter Unit, 5.0 μ m PTFE, PP, ThermoQuest) into a
27
28 vial and an 20 μ l aliquot injected (always within 6 hours) onto the HPLC column.
29
30
31
32
33

34 35 36 *Identification and Quantification* 37

38 HPLC was performed using a Hewlett-Packard HP 1100 liquid chromatograph (Wallbron,
39
40 Germany) equipped with diode array detector (DAD) and autosampler. A sample amount
41
42 of 20 μ l was applied to the separating column (250x4 mm), LiChrospher 100 RP-18 (5 μ m),
43
44 Merck, with precolumn (4x4 mm), Li Chrospher 100 RP-18 (5 μ m), Merck. Optimization
45
46 studies showed a methanol-water mixture to be suitable as mobile phase for separation; the
47
48 mobile phase gradient being 10% methanol held for 5 min, changed to 80% over 15 min,
49
50 and held at 80% methanol for 5 min. Total run time was 25 min, post time was 5 min. The
51
52 flow rate was 1 ml/min, the column temperature being 35°C. All analyses were run in
53
54 duplicate. For identification of agaritine the retention time, DAD spectra and peak purity
55
56
57
58
59
60

1 software function were used. Agaritine was detected at 237 nm and quantified by
2
3 comparing the peak area of the analysed sample with the peak area for known amounts of
4
5 the pure standard. Free amino acids that strongly absorb in the UV were shown not to
6
7 interfere with the agaritine peak. The correlation coefficient of the UV spectra (normalized
8
9 absorbance) of agaritine in standard solution and in a real sample was 0.999. The
10
11 chromatograms and UV spectra of the agaritine standard and an *Agaricus campestris*
12
13 sample are shown in Figure 2. The detector response was linear in the range 0.2 µg/ml –
14
15 2.0 mg/ml, the equation of the linear regression of the calibration curve being $y=31.325x +$
16
17 17.584, with a correlation coefficient of $R^2=0.9999$.. Under the experimental conditions
18
19 described for sample preparation, the limit of detection for the method was 0.02 µg/ml
20
21 (based on a signal/noise of 3:1), corresponding to 0.2 mg/kg fresh weight of mushroom,
22
23 limit of quantification was 0.6 mg/kg. The repeatability of measurements at agaritine levels
24
25 commonly found in fresh mushroom samples (200 mg/kg), expressed as the relative
26
27 standard deviation, was 4.5% for six replicates. Method validation has been presented
28
29 elsewhere (Schulzová et al. 2002).

50

51 Results

52 Mushrooms of the genus *Agaricus* were collected in various regions of the Czech Republic
53
54 during different periods of the growing seasons 1998-2001, and identified by an
55
56 experienced mycologist. Fifty-three different species were found. Table II shows the
57
58
59
60

1
2 average agaritine contents of the various *Agaricus* species identified, and, where
3
4 appropriate, the range in agaritine content, without controlling for mushroom size. When
5
6 the average agaritine content was calculated, a value of 50% of the detection limit was used
7
8 for the samples in which no agaritine could be detected. Only a few samples were available
9
10 for many of the more uncommon *Agaricus* species.
11
12

13 [Table II inserted about here.]
14
15
16
17
18

19 A significant difference in agaritine content was observed between species. The amounts
20
21 detected in individual species varied from non-detectable levels up to several g per kg fresh
22
23 weight. One sample of *A. elvensis* contained 10 g/kg fresh weight. Some species were
24
25 characterized by low agaritine content (<100 mg/kg fresh weight), others by intermediate
26
27 (100-1000 mg/kg fresh weight) or high (>1000 mg/kg fresh weight) levels of agaritine. It
28
29 should be noted that the allocation of species to groups having these arbitrarily set borders
30
31 is hampered by the low number of samples analysed for many species, resulting in less
32
33 reliable values of average agaritine content.
34
35
36
37

38 [Table III inserted about here.]
39
40
41
42

43 Nine of the 53 species analysed in our study contained less than 100 mg agaritine/kg fresh
44
45 weight (Table III), which was the level chosen defining mushrooms with a low agaritine
46
47 content. Of these nine species with low agaritine content only the relatively rare *A. maskae*,
48
49 *A. silvaticus* var. *pallidus*, and possibly also *A. caroli* are sought after by mushroom
50
51 connoisseurs. None of them are common mushrooms.
52
53
54
55
56
57
58
59
60

1
2 Twenty-four of the 53 analysed *Agaricus* species contained high levels of agaritine, more
3
4 than 1000 mg/kg fresh weight (Table III). In 20 species intermediate levels of agaritine
5
6 were found, 100-1000 mg/kg fresh weight (Table III), not deviating substantially from the
7
8 levels reported to occur in the cultivated mushroom, *A. bisporus*.
9

10
11
12 For the seven species for which more than 10 mushroom samples were analysed (*A.*
13
14 *arvensis*, *A. bitorquis*, *A. bisporus* var. *bisporus* (*A. brunnescens*), *A. campestris*, *A.*
15
16 *maleolens*, *A. silvaticus*, and *A. xanthoderma*) it was studied whether a correlation could be
17
18 found between the agaritine content and size of the mushroom, phenology, year of
19
20 collection, or site of collection.
21
22
23
24
25

26
27
28 No correlation could be found between diameter of the mushroom cap and its agaritine
29
30 content. A typical example of the poor correlation between cup size and agaritine content is
31
32 demonstrated by *A. arvensis* ($r = 0.033$; n.s.), Figure 3. These observations contradict the
33
34 findings of Stijve et al. (1986), that smaller fruit bodies of *A. arvensis* and *A. augustus*
35
36 contain higher amounts of agaritine than bigger mushrooms of the same species. There was
37
38 also no correlation in our studies between week of the year when the mushrooms were
39
40 collected and their agaritine content (data not shown).
41
42
43
44
45
46
47
48
49

[Figure 3 inserted about here.]

50
51
52 Among the 13 *Agaricus* species of which enough mushroom samples had been collected
53
54 over more than one year, there was in general no statistical difference in the average
55
56 agaritine content between years (shown by students t-test). The only data that reached
57
58
59
60

1
2 statistical significance were those of *A. maleolens*. In the years 1998 and 1999 *A. maleolens*
3
4 contained significantly lower levels of agaritine (51 ± 90 and 25 ± 54 mg/kg fresh weight,
5
6 respectively), than in year 2000 (165 ± 50 mg/kg fresh weight), t-test, $p=0.023$. During the
7
8 first two years the agaritine content was below the detection limit of the analytical method
9
10 in the majority of the samples, whereas none of the samples collected in year 2000
11
12 contained below 100 mg/kg fresh weight. It is our interpretation that this significant
13
14 difference might have disappeared had larger number of mushroom samples been analysed.
15
16
17

18
19
20
21 No correlation could be found between agaritine content and geographical region where the
22
23 mushrooms were collected (data not shown).
24
25
26

27
28
29 In addition to analysing for agaritine in the different *Agaricus* species, we also analysed for
30
31 agaritine in four species belonging to each of the related genera *Leucoagaricus* and
32
33 *Macrolepiota*. If agaritine occurs in mushroom species outside the genus *Agaricus*,
34
35 *Leucoagaricus* and *Macrolepiota* are the genera where agaritine might be found. As shown in
36
37 Table IV, one of the four *Macrolepiota* species, *M. konradii*, contained low amounts of
38
39 agaritine, 42 mg/kg fresh weight. Agaritine was also detected in three of the *Leucoagaricus*
40
41 species – *L. bresadolae*, *L. cretaceus*, and *L. naucinus* - but here the contents were higher, up
42
43 to 838 mg/kg fresh weight (Table IV). As agaritine has been reported to occur in the
44
45 cultivated Oyster mushroom *Pleurotus ostreatus* (Burini et al., 1999), we also analysed for
46
47 agaritine in this mushroom but found none.
48
49

Discussion

Two research groups, one from the USA and the other from Switzerland, have previously analysed wild-growing *Agaricus* and non-*Agaricus* species for agaritine. Levenberg (1964) examined boiled press-juice extracts from as many as 45 representative genera of wild basidiomycetes collected in the USA. As part of this survey, fruit bodies of 15 different species belonging to the genus *Agaricus* were analysed. Unfortunately, Levenberg used a nomenclature for the mushroom that hardly fit with that used in Europe today. Of the 15 *Agaricus* species, ten were reported to contain agaritine in quantities comparable to those found in *A. bisporus*, whereas five species were devoid of the compound (Table V). The limit of detection for the analytical method (spectrophotometric determination of agaritine by measurement of its rate of enzymatic hydrolysis) used by Levenberg (1964) was not reported. The single sample of fresh *A. bisporus* analysed for its agaritine content was reported to contain 3300 mg agaritine/kg dry weight, which corresponds to approximately 330 mg/kg fresh weight.

[Table V inserted about here.]

Subsequently, Swiss investigators reported HPLC (with a limit of detection in the region 20-25 mg/kg) and thin layer chromatography data on freeze-dried mushrooms, indicating that some wild-growing *Agaricus* species contain substantially higher amounts of agaritine than the cultivated *A. bisporus* (Stijve et al. 1986; Stijve and Pittet 2000). Because a considerable time had elapsed between picking of some mushroom samples and freeze-drying, the latter investigators were unsure that the amounts detected were the

1
2 characteristic levels of freshly harvested wild mushrooms and, therefore, did not give
3
4 specific information on the quantity of agaritine in the various species.
5
6
7

8
9 The agaritine contents given for the various *Agaricus* species in the present study should
10 fairly accurately describe the levels in freshly collected mushroom samples, at least when
11 the number of samples studied for a species have been large enough. Several factors may
12 influence the agaritine content of a mushroom. Studies performed with the cultivated
13 *Agaricus bisporus* have revealed that, in addition to hereditary factors, cultural practice
14 employed in production, stage of cropping-cycle (flush), and maturity of mushrooms at
15 harvest may influence the agaritine level in the mushroom (Andersson and Gry 2004).
16 Some of these factors are likely to influence the agaritine content also of wild-growing
17 species. The length of storage after harvest and the conditions during storage are other
18 factors that may influence the agaritine content (Andersson and Gry 2004). This is
19 exemplified by the data given in Table I. The average level of agaritine in *A. bisporus*
20 obtained directly from the growers was 723 ± 276 mg/kg fresh weight, whereas it was 475
21 ± 221 mg/kg fresh weight in mushrooms purchased on the open market. We have
22 minimized the potential influence of storage on the agaritine content in the present study by
23 analysing samples within three days after being collected.
24

47

48 Already in 1983, Speroni and co-workers suggested that wild-growing *Agaricus*
49 mushrooms contain higher amounts of agaritine than the corresponding cultivated
50 mushrooms. These investigators had noted that a cultivated strain of *A. bisporus* with
51 brown colour phenotype, PSU-351, which was only recently isolated from nature,
52 contained higher agaritine levels than other cultivated *A. bisporus* strains. It was
53
54
55
56
57
58
59
60

1
2 hypothesised that this strain had not yet adapted to the less stressing environmental
3
4 conditions during cultivation and not yet lost or reduced its inherited ability to produce
5
6 compounds inhibiting growth of certain competing fungi. A similar observation is made in
7
8 the present study. In the Czech Republic, it is strains of *A. bitorquis* and '*A. hortensis*' that
9
10 are cultivated. Samples of these cultivated strains have been reported to contain
11
12 comparable levels of agaritine, varying between 165 and 457 mg/kg fresh weight, with an
13
14 average content of 272 mg/kg fresh weight (Schulzová et al. 2002). As shown in Table II,
15
16 *A. bitorquis* and *A. bisporus* collected from nature contain significantly higher amounts of
17
18 agaritine, 1 473 and 746 mg/kg fresh weight, respectively.
19
20
21
22
23
24
25

26 Although too few samples were analysed for some *Agaricus* species to prove their normal
27
28 agaritine content, enough samples were analysed to conclude on the agaritine content for
29
30 other species. As shown in Table II and III, no less than 24 of the studied species contained
31
32 agaritine levels above 1000 mg/kg fresh weight. This amount should be compared with the
33
34 levels commonly found in *A. bisporus*, 200-500 mg/kg fresh weight. The highest amounts
35
36 were observed in *A. elvensis* (mean 4445 mg/kg), *A. purpurellus* (4100 mg/kg), *A. augustus*
37
38 (3995 mg/kg), *A. fissuratus* (3526 mg/kg) and *A. sagatus* (3479 mg/kg). As there is an
39
40 ongoing discussion whether it is advisable or not to consume fresh cultivated mushroom
41
42 (Toth 2000; Andersson and Gry 2004), it seems highly questionable to advise consumption
43
44 of wild-growing *Agaricus* species with even higher agaritine contents than the cultivated
45
46 species. Some of the species with a high agaritine content, however, have a firm reputation
47
48 as being good or even excellent culinary delicacies, e.g. *A. augustus*, *A. fissuratus*, *A.*
49
50 *essettei* and *A. substramineus*. On the other hand, as indicated in Table II, some of them are
51
52
53
54
55
56
57
58
59
60

1
2 recognised as bio-accumulating cadmium and other heavy metals from the soil (Řanda and
3
4 Kučera 2004)
5
6
7
8

9
10 The present study aimed at identifying tasteful, non-toxic *Agaricus* species with a low
11 agaritine content. Such species would be potential sources for strain development for the
12 mushroom cultivation industry, could it be shown they are devoid of other constituents
13 with potentially harmful effects. Only nine of the analysed *Agaricus* species had an
14 agaritine content below 100 mg/kg fresh weight. Of these at least five should be classified
15 as non-edible as they may give rise to gastrointestinal symptoms due to formation of
16 phenol. Based on the agaritine data presented in the present report, the most promising
17 species for strain development seem to be *A. caroli*, *A. maskae*, *A. silvaticus* var. *pallidus*,
18 and possibly *A. squamulifer*. Additional studies are required to establish whether these
19 species fulfil the criteria necessary to be good substitutes for *A. bisporus* as cultivated
20 mushrooms.
21
22

24
25
26
27
28
29
30
31
32
33
34
35
36
37
38

39 We have not addressed the question whether the presence of agaritine within the genus
40 *Agaricus* may have chemotaxonomic significance. However, we have noted that the
41 various sections of the genus *Agaricus* seem to be characterized by different abilities to
42 produce agaritine (Table IV). Stijve et al. (1986) have made a similar observation.
43
44
45
46
47
48
49
50

51 The question whether agaritine may be found in mushrooms outside the genus *Agaricus*
52 has been addressed also by other investigators. Levenberg (1964) was unable to detect
53 agaritine in any of the 30 non-*Agaricus* species analysed (detection limit for the analytical
54 technique not mentioned), and Stijve and co-workers in any of 39 wild-growing and 30
55
56
57
58
59
60

1
2 cultivated non-*Agaricus* species (Stijve et al. 1986; Stijve and Pittett 2000). Two reports on
3
4 popular cultivated mushrooms are in conflict with these data. Hashida et al. (1990) found
5
6 very low levels of agaritine in shiitake (*Lentinus edodes*), 0.82 mg/kg fresh weight, and
7
8 Burini et al. (1999) very high levels (average level 680 mg/kg fresh weight; range 478-905
9
10 mg/kg) in the Oyster mushroom (*Pleurotus ostreatus*). With such low quantities of
11
12 agaritine in fresh shiitake, it came as no surprise that Andersson et al. (1999) were unable
13
14 to detect agaritine in a Swedish sample of canned shiitake, and that Stijve et al. (1986)
15
16 were unable to detect agaritine in fresh shiitake using an analytical technique having a limit
17
18 of detection around 20-25 mg/kg fresh weight. Further studies are needed to determine
19
20 whether fresh shiitake mushrooms contain low levels of agaritine. The report that agaritine
21
22 occurs in the Oyster mushroom, is, however, most likely an artefact due to the use of an
23
24 unspecific analytical method. The only other explanation, that the cultivated strains of
25
26 *Pleurotus ostreatus* may vary substantially in their ability to produce agaritine seems less
27
28 likely. Neither Swiss investigators (Stijve et al. 1986; Stijve and Pittett 2000), nor we in the
29
30 present study could identify agaritine in this species, although the limit of detection was as
31
32 low as 0.2 mg/kg fresh weight in the present study. Furthermore, there is no indication that
33
34 agaritine production can be suppressed to negligible levels by the method of cultivation.
35
36
37
38
39
40
41
42
43
44
45

46 However, the data in the present study clearly show that agaritine is present in some
47
48 species of the genera *Leucoagaricus* and *Macrolepiota*, which both are saprotrophic
49
50 mushrooms closely related to the genus *Agaricus* (Singer 1986). The compound was
51
52 detected in *Leucoagaricus bresadolae*, *L. cretaceus*, *L. naucinus*, and *Macrolepiota*
53
54 *konradii* (detection limit 0.1 mg/kg), but not in one other species of *Leucoagaricus* and
55
56
57
58
59
60

1
2 three other species of *Macrolepiota* (Table IV). Stijve et al. (1986) found no agaritine in
3
4 *Leucoagaricus pudicus*, *Macrolepiota procera* and *Macrolepiota rachodes*.
5
6
7
8

9 10 **Acknowledgements**

11 The synthesis of agaritine was supported by a grant from the Nordic Council of Ministers,
12 and the chemical analysis by grant MSM 6046137305 given by the Ministry of Education,
13 Youth and Sports of the Czech Republic. We are very much indebted to Jan Borovička, Jiří
14 Burel and Henning Knudsen for very valuable information on *Agaricus* taxonomy.

Agaritine content of 53 *Agaricus* species collected from nature

For Peer Review Only

Table I. Agaritine content (mg/kg fresh weight) of methanolic extracts of fresh *Agaricus bisporus* as determined by HPLC. If samples were not freeze-dried (which does not influence the agaritine level) shortly after being obtained, they were analysed within 24 hours.
