Contractual Implications of International Trade in Tacit Knowledge

Abstract

This paper searches for evidence on the additional difficulty the parties have in contracting for the transfer of know-how relative to the transfer of patented technology. A sample of contracts for the acquisition of technology by Spanish firms in 1991 is analyzed to find a positive relationship between contract duration and the likelihood of transferring know-how in unaffiliated transfers. It is also found that technical assistance is bundled together with the transfer of know-how, suggesting that the parties try to mitigate opportunistic behavior on the licensor's side.

1. Introduction

The transmission of tacit knowledge has some problems inherent to it that are not present in the transfer of other types of technology. These problems stem from the fact that it is uncodified knowledge, which allows neither contracts being written contingent on technology characteristics nor legal protection of technology. This characteristic causes moral hazard problems on both sides, first described in Arrow (1962). Moral hazard problems are less acute in the case of codified, legally protected technology. On the one hand, codification implies that the relevant characteristics of the technology can be described, which allows the parties to write contracts contingent on them. On the other hand, legal protection against imitation dramatically limits potential moral hazard problems both on the licensor and on the licensee's side.

This paper studies the determinants of the transfer of patented technology and know-how and the role of the provision of technical assistance services in the transfer of tacit knowledge. The empirical analysis is carried out using a sample of technology-importing contracts signed by Spanish firms in 1991. One of the findings of the paper is that while contract duration has a positive effect on the probability of transmission of know-how in unaffiliated transfers, it has no effect on the probability of a patent being transferred. Contract duration is defined as the number of years the parties agree the relationship to last at the time of signing the contract. Another finding is that the provision of technical assistance eliminates the effect of contract duration on the likelihood of transferring know-how. It will be argued that this is consistent with technical assistance being used as a safeguard against the licensor behaving opportunistically.

The analysis of international technology transfer is important for its impact on productivity and growth, as found, at a macroeconomic level, in Attella and Quintieri (2001), Engelbrecht (1997) or Frentzen (1998). Descending to a microeconomic level, although several studies, such as Anton and

1
2
3 Yao (1992, 1994) or King (2003) analyze theoretically the transfer of unprotected technology, the
4
5 empirical evidence on the actual licensing procedures is very scarce. Among the few studies using
6
7 transaction-level data, Caves et al (1983) summarize the difficulties faced when transferring technology,
8
9 and Anand and Khanna (2000) find inter-industry differences in contractual practices. Kim (2004) finds
10
11 that the strength of intellectual property protection and prior licensing activity, among other factors,
12
13 increase the propensity of US firms to license their technologies. Macho-Stadler et al (1996) and Mendi
14
15 (2005) use the database employed in this article, although the focus in these articles is on explaining
16
17 scheduled payments.
18
19
20

21
22 Contract duration has not been the main object of theoretical or empirical studies on contracts
23
24 for the international transmission of technology. The temporal dimension of the agreement has been
25
26 typically overlooked in the literature, focusing on difficulties to contract due to asymmetric information
27
28 or the risk inherent to the transmission of the technology, but never considering the case of the
29
30 relationship lasting for several periods. Thus, one of the contributions of this paper is to explicitly
31
32 consider the temporal dimension of contracts and to analyze whether contract duration varies with the
33
34 type of technology to be transferred.
35
36
37

38
39 In this paper, contract duration is considered to be exogenous, and determined by how long will
40
41 the technology be useful before its obsolescence. It is assumed that licensors sell different product
42
43 and/or process technologies with different expected remaining useful lives. Once these useful lives
44
45 expire, technologies become obsolete and therefore, worthless. These remaining useful lives at the time
46
47 of contracting actually determine contract duration.
48
49

50
51 The estimated effect of contract duration also suggests that the transfer of know-how is much
52
53 more difficult than that of patented technology. This way, duration affects the likelihood of know-how
54
55 being transferred because longer contracts reduce the scope for moral hazard on both sides. Hence, if
56
57 the relationship is scheduled to be short-lived, the temptation of the parties to breach the contract is
58
59
60

1
2
3 greater than in the case of longer relationships (see Klein, 1996). Foreseeing this, the parties may be
4
5 unable to sign an agreement in the first place, and therefore, the observed distribution of contract
6
7 duration in those contracts that include the transmission of know-how will be skewed to the right.
8
9

10
11 Regarding the provision of technical assistance services to facilitate the transmission of tacit
12
13 knowledge, Arora (1996) presents evidence of complementary inputs being bundled together with the
14
15 transfer of know-how, arguing that they mitigate moral hazard on the licensor's side. In the presence of
16
17 potential moral hazard problems on the licensor's side, technical assistance can be a safeguard against
18
19 this opportunistic behavior. It can be regarded as commitment by the licensor to provide the licensee
20
21 with the first-best level of technology, as long as providing technical assistance is costly to the licensor
22
23 of the technology. Arora (1996) also finds that patents are bundled together with know-how, a result
24
25 not found in the present paper.
26
27

28
29 However, a positive relationship between the transfer of know-how and the provision of
30
31 technical assistance should be interpreted with caution, since, by the non-codifiability of know-how, the
32
33 provision of technical assistance is the natural way to transfer tacit knowledge, independently of any
34
35 moral hazard problems. The result obtained in this paper is that transfers of know-how, but not of
36
37 patents, are associated with the provision of technical assistance. The additional result that technical
38
39 assistance eliminates the effect of duration on the likelihood of transferring know-how constitutes
40
41 further evidence consistent with technical assistance mitigating moral hazard problems on the licensor's
42
43 side.
44
45

46
47 The organization of the paper is as follows. Section 2 discusses how contract duration may
48
49 affect the transfer of know-how and why the parties may be interested in including technical assistance
50
51 in the agreement. Section 3 describes the data, which will be analyzed in Section 4. Finally, Section 5
52
53 summarizes the main conclusions from the empirical analysis carried out in this paper.

2. Technology trade, contract duration, and the provision of technical assistance

This section discusses how the transfers of patented technology and of know-how are differently affected by moral hazard problems. Furthermore, it will be discussed how contract duration may alter the incentives of the parties to behave opportunistically. The hypotheses to be tested in the empirical section will also be presented.

Patented technology and know-how differ substantially in their tacitness. The former type of technology is codified knowledge, which allows for its description and delimitation of what is included and what is not included in the patent, and therefore, what is and what is not legally protected against imitation. Furthermore, the possibility of describing the object of a patent permits that contracts be written based on the characteristics of patented technology, since it is possible for third parties to verify these characteristics. By contrast, know-how is tacit, uncodified knowledge. This characteristic prevents the parties from writing contracts based on technology characteristics, which are non verifiable by third parties. This tacitness also impedes that know-how receive legal protection against imitation.

There is less room for potential moral hazard problems in the transfer of a patent than in the transfer of know-how. In the latter type of transfers, the licensee may renege on payments, and the licensor may provide a suboptimal type of technology, see for instance Choi (2001). If this threat is serious enough, in some cases the agreement might not be signed at all. In other cases, the parties will be forced to include safeguards in order to actually sign the contract.

In this paper, contract duration refers to what the parties expect the relationship to last given their information at the time of signing the contract. This will not always be equal to actual contract duration, since some contracts may be terminated early. Incentives to deviate from honest behavior differ with contract duration. If the parties sign a short-term contract, they have a smaller incentive to cooperate in the successful implementation of the technology than in the case of a longer relationship, since the opportunity cost of breaching the contract is greater the longer the remainder of the

1
2
3 relationship. Of course, for this effect to exist, there must be some way the non-deviant can punish the
4 deviating firm. In the case of the licensee deviating by renegeing on its payments due, the licensor can
5 license another firm, thus reducing the original licensee's profits, a reduction that will be increasing in
6 contract duration. Similarly, if the licensor does not provide the first-best technology to the licensee so
7 as to save in costs, the opportunity cost to the licensor is the fact that it is receiving lower revenues.
8 This opportunity cost is also increasing in contract duration.

Legal protection of technology is crucial in determining how profitable contract breaching is, and thus, to analyze whether contract duration will have any effect at all in the likelihood of observing specific types of technology being transferred. If legal protection of the technology is strong, for instance in a patent licensing contract, the temptation to cheat is reduced. In this case, contract duration should not be a factor in determining how likely to be signed these contracts are, and therefore, its effect on the likelihood of observing the transfer of a patented technology should be null.

By contrast, this same argument suggests that the likelihood of know-how being transferred should be non-decreasing in contract duration. For some short-term contracts, opportunistic behavior by either party may prevent the parties from actually signing the contract. The incentives to not behaving opportunistically increase in contract duration, since the profit from continuous cooperation more likely exceed the instantaneous gain from deviation.

This double prediction is precisely what will be tested in the empirical section. Using data from contracts for the imports of technology by Spanish firms in 1991, it will be analyzed whether contract duration affects the likelihood of observing a patent and know-how. If moral hazard inherent to the transfer of know-how is an issue, then duration should positively affect the likelihood of know-how but should have no effect in the transfer of a patent. However, evidence on the existence of such relationship cannot be regarded as a definitive proof of a direct causality effect of duration on the likelihood of transferring know-how, since the observed correlation could well be via a selection effect.

1
2
3 Furthermore, the available data does not allow the empirical analysis from ruling out alternative
4 explanations. Indeed, a positive effect of duration may just come from the fact that the transmission of
5 know-how takes longer to be carried out.
6
7
8
9

10 Related to the problems inherent to the transfer of tacit knowledge, the provision of technical
11 assistance can be a way to ensure that the licensor indeed supplies the first-best level of technology. In
12 some sense, see Arora (1992, 1996), it acts as a commitment device, if the provision of technical
13 assistance is costly to the licensor. What will be analyzed empirically is whether technical assistance is
14 more likely to be present in transfers of know-how than of patents. Additionally, it will be tested
15 whether or not contract duration affects differently the likelihood of including know-how, depending
16 on the inclusion of technical assistance in the original agreement. If the provision of technical assistance
17 indeed solves the moral hazard problems on the licensor's side, conditional on moral hazard problems
18 on the licensee's side being relatively less important, then duration should not affect the likelihood of
19 transferring know-how in contracts where technical assistance is included. By contrast, in those
20 contracts where technical assistance is not included, contract duration should still have a positive effect
21 on the probability of transferring tacit knowledge. Evidence for this effect will also be searched for in
22 the empirical section.

43 **3. The data**

44
45 The dataset is obtained after examination of the records of the Spanish Ministry of Industry. All
46 Spanish firms that imported technology were required, up to 1992, to report the terms of the
47 technology purchase. The importer of the technology had to file a form, named 'TE-30', with the
48 'Servicio de Información y Transferencia de Tecnología' (Technology Transfer Office), a branch of the
49 Spanish Ministry of Industry. In some cases, in addition to this form, the firm included the actual
50
51
52
53
54
55
56
57
58
59
60

1
2
3 contract, although this was optional. This type of control is no longer allowed by the European Union,
4
5 and thus filing was terminated in 1992.
6

7
8 The Spanish firm, which was the licensee in all cases, had to describe in this form some features
9
10 of the technology being purchased or licensed. First, the licensee reported whether that technology
11
12 could be classified as a product and/or a process technology. The Spanish firm also indicated whether
13
14 or not the agreement included a transfer of a patent, a utility model (a minor invention also legally
15
16 protected), know-how, an industrial design or software. In some cases, the contract includes the
17
18 transfer of several of these technology types. Out these types of technology, know-how is the only one
19
20 that constitutes tacit knowledge, since the rest of them are codified and receive some legal protection
21
22 against imitation, whereas legal protection is strongest in the case of a patent. In the same form, the
23
24 Spanish firm also reported whether the contract was a licensing contract, where only the right to use a
25
26 given technology was purchased, or it was an actual sale, where the Spanish firm acquired ownership of
27
28 the technology. In the empirical analysis, all the variables constructed using these items will be
29
30 dichotomous, taking values zero or one, since what is observed is the Spanish firm reporting whether
31
32 or not the contract includes the transfer of these technological characteristics.
33
34
35
36
37

38 Regarding information on the Spanish firm, in addition to the industry of its main activity, it
39
40 reported its sales in the year before the filing of the form. Also included was information on what kind
41
42 of linkages licensor and licensee had, if any. The licensee, when applicable, had to report the percentage
43
44 of its equity owned by the licensor, or if both firms had a common parent. Using this information, the
45
46 observations can be classified into affiliated and unaffiliated. Two parties are affiliated if either there is a
47
48 direct participation of the licensor of 50% or more in the licensee's equity or if both firms have a
49
50 common parent. The Spanish firm also reported whether it performed R&D, although there was no
51
52 information on the percentage of sales devoted to this activity. Regarding the licensor's characteristics,
53
54 both its industry and country appear on the form. The form also contains a licensee's estimate of
55
56
57
58
59
60

1
2
3 scheduled payments to be made during the initial five years of the contract, distinguishing between
4 fixed and variable payments. If the relationship was scheduled to last longer than five years, the licensee
5 was not required to provide an estimate of payments. The impact of some characteristics of the
6 transferred technology on payment schemes has been analyzed in Mendi (2005).
7
8
9
10
11

12 Whenever the contract is filed together with the form, more variables are observable, by
13 inspection of the contract clauses. In particular, contracts stipulate the duration of the agreement,
14 which is the number of years the parties expect the relationship to last at the time of signing the
15 contract. Thus, for those observations where the contract was filed together with the form, the duration
16 variable just takes the value specified in the contract. For some cases in which only the form was filed,
17 duration can be inferred by observing in what period scheduled payments stopped. In these cases,
18 duration is the last year for which positive payments were scheduled. There are some observations for
19 which duration is neither observed nor inferred, making duration missing in 27 occasions.
20
21
22
23
24
25
26
27
28
29
30

31 Concerning the sampling process, the Spanish Ministry of Industry followed no systematic
32 criterion in the classification of the forms. They were literally stored in boxes as they were received and
33 sent to the archives in a basement located in the central offices of the ministry, in Madrid. This suggests
34 that there was no significant bias arising from the sampling procedure, which was to randomly select
35 boxes and inspecting the forms contained in them. The sample size is conditioned by the fact that the
36 author obtained permission only for two weeks to copy the contents of the forms manually.
37
38
39
40
41
42
43
44

45 Out of the 5168 forms filed in 1991, which are described in Pérez (1996), the sample used in
46 the empirical section of this paper includes 165 observations. 212 observations were collected with a
47 clear technological content, since they specified the transfer of a patent, a utility model, an industrial
48
49
50
51

53
54
55
56
57
58
59
60

1
2
3 design, know-how, or software (not for resale¹). This criterion leaves out of the sample contracts where
4 the technological content is less clear, for instance those where the licensee is just a software retailer. In
5 addition to the 27 missing values of the duration variable, sales are not reported in 22 cases. This means
6 that, out of the mentioned 212 observations with a clear technological content, only 165 observations
7 are used in the empirical analysis².
8
9
10
11
12
13

14
15 Table 1 and 1b present selected characteristics of the contracts, classified by industry of the
16 licensee. The data have been classified into five industry groups: Agriculture; Energy, Minerals, and
17 Chemicals; Metal Transformation; Other Manufacturing and Construction; Services. These industry
18 groups correspond to industries 0, 1-2, 3, 4-5, and 6-9 respectively, according to Spanish classification
19 of industries (CNAE-74).
20
21
22
23
24
25

26 [Insert Tables 1a and 1b here]
27
28

29 As it can be seen in Table 1a, there is some variation across industries in technology
30 characteristics. Most contracts made in Energy, Minerals and Chemicals include the transfer of know-
31 how, whereas less than half of the contracts in Services, Other Manufacturing, Construction, or
32 Agriculture include the transmission of this type of technology. By contrast, the proportion of contracts
33 that include the transfer of a patent is highest in Agriculture, and in the remainder industry groups, it is
34 below one third. This stresses the fact that patented technology, which has received significant attention
35 in the Economics literature, represents a relatively small part of the international market for technology.
36 This result also holds when total payments in transfers including a patent and not including one are
37 considered.

45
46
47
48

49
50
51
52 ¹ Included in the sample are transfers of software only if it is to be used by the licensee. There are some contracts in the
53 sample where the licensee merely acts as a software retailer. These transfers have been explicitly excluded from the final
54 sample.
55
56

57
58 ² In two cases, neither duration nor sales were observed.
59
60

1
2
3 The provision of technical assistance services is more frequent in Metal Transformation and
4 Services, and rarely observed in Agriculture and Other Manufacturing and Construction. On the other
5 hand, process technologies are prevalent in Services, and no contract in Agriculture fall into this
6 category. In this paper, a given technology is considered to be of a process type if the licensee classifies
7 it as a process but not product technology.
8
9

10
11 Table 1b summarizes information on other variables also employed in the empirical analysis.
12 Unaffiliated transfers are prevalent in all industries, with Agriculture having the highest percentage, over
13 80%. This variable is also dichotomous, taking the value zero if unaffiliated, and one if the transfer is
14 made between affiliated parties. The transfer of ownership is rarely observed in these contracts, less
15 than 10% overall, implying that most contracts are indeed licensing contracts. Ownership is transferred
16 about 15% of the times in Energy, Minerals, and Chemicals and in Metal Transformation, whereas in
17 the remainder industries it is rarely transmitted. Duration, measured in years, is also highest in
18 Agriculture, and in the neighborhood of five years in the case of the remaining industries, except for
19 Services, which presents much shorter contracts on average. Finally, there is a high degree of
20 heterogeneity across industries in the licensee's sales, measured in millions of Spanish pesetas with the
21 average firm in Energy, Minerals and Chemicals being 20 times as big as the average firm in Agriculture.
22 In the empirical analysis, the logarithm of this variable will be used.

45 **4. Empirical evidence**

46
47 This section presents some empirical evidence drawn from the sample of contracts described in
48 the previous section. First, evidence is presented on the relationship between know-how, patents, and
49 technical assistance. Then, the factors that determine the transfers of patented technology as well as
50 know-how are analyzed. Finally, evidence on the role of technical assistance in the transfer of tacit
51 knowledge is presented.

4.1. Transfers of patents, know-how, and provision of technical assistance services

Tables 2a, 2b, and 2c are cross tabulations of the indicators of the transfer of a patent, the transfer of know-how, and the provision of technical assistance services. First, Table 2a, which cross-tabulates indicators of the transfer of patents and know-how, shows that rarely is patented technology transferred together with tacit knowledge, only 17 out of 165 observations. The non-complementarity between these two types of technology is confirmed by the value of the Chi-squared test, which is statistically significant at the 5% level.

Tables 2b and 2c are aimed at providing evidence of whether technical assistance is likely to be bundled together with a particular type of technology. Table 2b presents the cross tabulation of know-how and technical assistance. It is clear that the transfer of know-how dramatically increases the likelihood of technical assistance being included in the contract. This is confirmed by the value of the Chi-squared test, statistically significant at the 1% level. By contrast, analyzing the relationship between the transfer of patented technology and the provision of technical assistance, the result is the opposite: Table 2c shows that the transfer of patented technology reduces the likelihood of including technical assistance in the contract, with a Chi-squared statistic that is significant at the 1% level.

Thus, technical assistance seems to be associated with the transfer of know-how, but not with that of a patent. This is consistent with the claim that the provision of technical assistance helps to mitigate potential moral hazard problems on the licensor's side, inducing it to transfer the first-best level of technology. However, this is not the only candidate explanation, since the relationship between know-how and technical assistance could also be due by the very non-codifiability of know-how. Indeed, technical assistance, which increases the direct contact between licensor and licensee, is the way the parties have to effectively transfer a kind of technology that is not codifiable. Table 4 will present further evidence on the role of technical assistance in the transfer of tacit knowledge.

4.2. Determinants of the transfer of patents and know-how

Table 3 presents estimated coefficients in a bivariate Probit model where the dependent variables are indicators of the transfer of patented technology and of know-how. This model allows for the error terms in both equations to be correlated. The evidence presented in Table 2a indeed suggests that such correlation should be taken into account. The specification whose coefficients are estimated is the following:

$$V_{1i} = \alpha_0 + \sum_{j=1}^4 \alpha_j Ind_{j,i} + \alpha_5 Link_i + \alpha_6 Pcs_i + \alpha_7 Duration_i + \alpha_8 Sameind_i + \alpha_9 \ln impts_i + \alpha_{10} \ln sales_i + \varepsilon_{i,1} \quad (1)$$

$$V_{2i} = \beta_0 + \sum_{j=1}^4 \beta_j Ind_{j,i} + \beta_5 Link_i + \beta_6 Pcs_i + \beta_7 Duration_i + \beta_8 Sameind_i + \beta_9 \ln impts_i + \beta_{10} \ln sales_i + \varepsilon_{i,2}$$

The vector of error terms is distributed $N\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}\right]$, and the observed dichotomous dependent variables are simply,

$$Patent_i = 1(V_{1,i} > 0) \quad (2)$$

$$KnowHow_i = 1(V_{2,i} > 0)$$

i.e. whether patented technology or know-how has been included in the contract.

Columns (i) and (ii) of Table 3 report estimated coefficients of the bivariate probit model using the full sample of contracts, whereas columns (iii) and (iv) report estimated coefficient using only unaffiliated contracts. The reason to consider the unaffiliated subsample isolately is that there might be significant differences between affiliated and unaffiliated transfers. Indeed, the literature typically assumes that moral hazard is less likely to be a problem in affiliated transfers. The regressors include four industry dummies, one for each industrial group except for Agriculture (*Ind* variables). *Link* is a dummy that takes the value 1 if the transfer is affiliated, and zero otherwise. *Duration* is contract duration in years. *SameInd* is a dummy that equals one if both parties to the contract are classified into

1
2
3 the same industry. A transfer between two firms in the same industry is assumed to suffer less from
4 asymmetric information problems. The *lnimpts* variable is the logarithm of the percentage of total
5 Spanish imports that came from the licensor's country of origin. It is a measure of asymmetric
6 information both on the licensee and the licensor's side, since a low value of this variable suggests less
7 commercial ties between Spain and the licensor's country, and thus less information about the
8 conditions of the Spanish market. Additionally, a low value also suggests that the licensee has less
9 information about the licensor. Finally, *lnsales* is the logarithm of sales of the Spanish firm in the year
10 prior to the signing of the contract, which had to be reported in the form. This controls for potential
11 differences between large and small firms in the type of technology that they acquire. For instance, if
12 the market value of patents is too high then maybe only large firms, which are assumed to be less cash
13 constrained, will be able to purchase patented technology.

21
22
23
24
25
26
27
28

29 None of the coefficients reported in column (i) of Table 3 is statistically significant, except that
30 on process technology, which is negative. Thus, most patented technology refers to new products
31 rather than improvements in the production of existing products. Neither affiliation nor contract
32 duration seem to affect the probability of patented technology being transferred, suggesting that the
33 legal protection that a patent receives is strong enough to mitigate possible moral hazard problems on
34 both sides.
35
36
37
38
39
40
41

42 By contrast, affiliation, process and the indicator of licensor and licensee belonging to the same
43 industry have positive, statistically significant effects in the likelihood of transferring know-how, as seen
44 in column (ii). The affiliation variable is indeed significant at the 1% level, suggesting a strong
45 relationship between affiliation and the transfer of know-how: internal transfers seem to be preferred
46 for the transmission of this type of technology. Duration has no statistically significant effect on the
47 likelihood of transferring know-how. The coefficients on the industry dummies, which are unreported,
48
49

51
52
53
54
55
56
57
58
59
60

1
2
3 are also insignificant in both equations. The logarithm of imports and logarithm of sales variables have
4 statistically insignificant effect on the likelihood of transferring either a patent or know-how.
5
6

7
8 The fact that there may be significant differences between affiliated and unaffiliated transfers in
9 the type of technology to be transferred suggests the separate analysis of unaffiliated contracts, which is
10 done in columns (iii) and (iv) of Table 3. Using the subsample of unaffiliated transfers, the effects of
11 the different regressors on the likelihood of transferring a patent are similar to those in column (i).
12 Besides the coefficient on process technology, which is negative, highly statistically significant but
13 smaller in absolute value than that in column (i), no coefficient is statistically significant. In particular,
14 duration does not appear to affect the likelihood of a patent being transferred. Concerning the reported
15 estimated coefficients in column (iv), which measures the impact of the regressors on the transfer of
16 know-how, those on process and same industry are positive and statistically significant, as they were in
17 column (ii) and now they are slightly greater in absolute value. The main difference is that now the
18 coefficient on duration is positive and statistically significant at the 1% level, suggesting that unaffiliated
19 contracts that stipulate know-how are significantly longer than those that do not include the transfer of
20 tacit knowledge. This relationship is consistent with duration reducing the licensor and licensee's
21 incentives to behave opportunistically, as discussed in the previous section. Also, the fact that the effect
22 appears only in unaffiliated transfers is consistent with this explanation, since moral hazard problems
23 are more acute in arm's-length transfers. However, there are other explanations consistent with this
24 finding, such as the transfer of tacit knowledge, especially to an unaffiliated party, requiring more time
25 than that of codified knowledge.

45
46
47
48

49 Additionally, if the parties belong to the same industry, it is more likely that they agree on the
50 transfer of know-how, with the coefficient on this variable in column (iv) being positive, statistically
51 significant, and greater in absolute value than that reported in column (ii). By its very nature, tacit
52 knowledge requires the licensee to be familiar with the procedures that know-how applies to, in a lesser
53
54
55
56
57
58
59
60

1
2
3 degree than in the case of a patent, where a description of it is available. This could explain the positive
4 relationship between the licensor and the licensee belonging to the same industry and the transfer of
5 know-how, as well as the insignificant effect on the transfer of a patent.
6
7
8
9

10 11 12 **4.3. The provision of technical assistance services**

13
14
15 Table 4 presents results of regressions that inquire into whether technical assistance is actually
16 bundled together with know-how in order to mitigate moral hazard problems on the licensor's side, as
17 proposed in Arora (1996). For that purpose, it will be analyzed if technical assistance eliminates the
18 effect of duration on the likelihood of transferring patented technology and know-how, within
19 unaffiliated transfers. The evidence suggests that technical assistance actually helps in the transmission
20 of know-how, but has no effect if a patent is to be transferred.
21
22
23
24
25
26
27
28

29
30 First, column (i) in Table 4 presents estimated marginal effects of a Probit specification where
31 the dependent variable is an indicator of the transfer of a patent, and the regressors are the same as in
32 the case of equation (1), except for the absence of the affiliation variable, since only the unaffiliated
33 subsample will be used, and of industry dummies, because of the low number of observations due to
34 the additional splitting of the sample into contracts which include technical assistance and contracts
35 which do not include it. In column (i) only observations where the contract does not stipulate the
36 provision of technical assistance are used, and no effect is statistically significant, except for that of the
37 technology being of a process type. On the other hand, column (ii) uses observations where the
38 technical assistance services are provided by the licensor. In this case, duration has a positive marginal
39 effect, and becomes statistically significant at the 10% level. If moral hazard on the licensor's side was a
40 major factor driving the likelihood of patented technology being transferred and technical assistance
41 helps mitigating this problem, then the effect of duration should have been positive if no technical
42 assistance services are provided, and null if technical assistance is provided.

54
55
56
57
58
59
60

Columns (iii) and (iv) do the same exercise but now the dependent variable is, in both cases, an indicator of the transmission of know-how. Now the difference between the estimated marginal effects of duration in columns (iii) and (iv) provides additional evidence consistent with technical assistance helping to mitigate moral hazard problems on the licensor's side. If no technical assistance is provided, the effect of duration is relatively large, increasing the likelihood of know-how being transferred by 7.7% per year of duration of the contract, and statistically significant at the 1% level. By contrast, in the subsample of unaffiliated transfers where technical assistance is provided, the effect of duration is much smaller in absolute value, and loses its statistical significance. Thus, in contracts that stipulate the provision of technical assistance, contract duration is less relevant in determining the likelihood of signing the contract, suggesting that the provision of technical assistance is a partial solution to moral hazard on the licensor's side. It is interesting to stress the asymmetry of this result comparing transfers of codified technology with tacit knowledge: technical assistance only helps in the case of tacit knowledge, which again suggests that moral hazard problems on the licensor's side indeed affect the likelihood of signing the contract.

Additionally, the transmission of technical assistance also makes the effect of the same industry variable less important, although it remains positive and statistically significant. An interpretation of this result is that technical assistance substitutes for lack of knowledge about the usual procedure in a different industry. The effect of the logarithm of imports variable is positive, statistically significant, and it is not influenced by the transmission of technical assistance: know-how tends to be acquired from countries with closer commercial ties with Spain regardless to the efforts made by the parties to reduce moral hazard on the licensor's side. This again is consistent with asymmetric information on variables other than technology characteristics worsening moral hazard problems on both sides.

Finally, the provision of technical assistance dramatically changes the effect of the licensee's size, switching from it being positive and statistically significant at the 5% level to negative and

1
2
3 statistically significant at the 1% level. A candidate explanation is that when no technical assistance is
4 provided, mostly larger firms acquire tacit knowledge because they can more easily bear the loss from
5 possible moral hazard on the licensor's side, and thus, the likelihood of the contract actually being
6 signed is smaller if the licensee is of a smaller size. On the other hand, if technical assistance is
7 provided, then there is less room for opportunistic behavior on the licensor's side, and thus, the true
8 distribution of licensees' sizes appears, with smaller firms more likely acquiring tacit knowledge. An
9 alternative explanation is that small firms lack the resources to maintain a permanent technical staff,
10 making them more dependent on technical assistance provided by the licensor.

24 **5. Conclusions**

25
26 This paper analyzes the determinants of the transmission of patented and of tacit technology,
27 with an emphasis on the effect of contract duration and on the role of the inclusion of technical
28 assistance. With this purpose, a sample of 165 contracts for the acquisition of technology by Spanish
29 firms from foreign sources in 1991 is analyzed empirically.
30
31
32
33
34
35

36 The analysis of the sample presents evidence of the positive effect of contract duration on the
37 probability of transferring tacit knowledge in unaffiliated transactions. By contrast, duration has no
38 effect if patented knowledge is to be transferred, regardless of the linkages between licensor and
39 licensee. An explanation for the difference between the two effects could be the legal protection that a
40 patent receives, which is absent if tacit knowledge is to be transferred. This constitutes a potential
41 source of moral hazard problems on the licensee's side. Additionally, the fact that tacit knowledge is
42 uncodified may be an additional source of moral hazard problems on the licensor's side. If the parties
43 sign a long-term contract, then moral hazard problems are less acute because the opportunity cost of
44 opportunistic behavior increases. Since the legal protection and codification of a patent reduce the
45 temptation to cheat, duration has no effect in this type of transfers, but the transfer of know-how,
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 lacking these two features, is sensitive to duration, which changes the parties' incentives to breach the
4
5 contract.
6

7
8 In addition to the previous argument, the positive effect of contract duration on the likelihood
9
10 of transferring know-how could also work by means of an increase in the likelihood of the parties
11
12 actually signing the contract if duration is long. If know-how is to be transferred and the expected
13
14 duration of the technology is short, then the potential moral hazard problems on both sides may be so
15
16 acute that the parties are not able to reach a successful agreement. The fact that duration affects the
17
18 likelihood of observing the transfer of know-how only within unaffiliated transfers suggests that the
19
20 problems associated with its transmission may be an important determinant in the successful transfer of
21
22 tacit knowledge.
23
24

25
26 The paper also investigates whether the parties include the provision of technical assistance as a
27
28 way to solve moral hazard problems on the licensor's side. Technical assistance can be seen as a
29
30 commitment by the licensor to provide the licensee with the first-best level of technology, if
31
32 contracting upon technological characteristics is impossible. The evidence presented in Tables 2 and 4
33
34 is consistent with the claim that these services are indeed used by the parties for this purpose: technical
35
36 assistance is associated with the transfer of know-how, but not of a patent, and the provision of
37
38 technical assistance services makes the effect of contract duration in the likelihood of transferring
39
40 know-how be statistically insignificant.
41
42
43

44
45 The evidence presented in this paper is, therefore, consistent with opportunistic behavior being
46
47 an important determinant of international transfers of technology. However, the data that is available
48
49 prevent this evidence from being fully conclusive, since there could be other explanations for the
50
51 results in Tables 2 and 3 not based on the interpretation proposed in this paper. However, the results
52
53 presented in Table 4, indicating the different role of technical assistance depending on the technology
54
55
56
57
58
59
60

1
2
3 type, constitutes additional evidence in favor of the explanation proposed in this paper. It would be
4
5 interesting to study whether this result is also found in other similar datasets.
6
7

8 The results obtained in this paper suggest that the legal protection offered by the patent system
9
10 in Spain in 1991 was sufficient to ensure that two unaffiliated parties interested in transferring
11
12 ownership or the right to use a patent were not refrained by potential moral hazard problems. By
13
14 contrast, the transfer of know-how was much more difficult because of its lack of legal protection and
15
16 its tacitness. Technical assistance services are introduced as a partial solution to this problem, but
17
18 whenever this service was not provided, the probability of transferring know-how depended on factors
19
20 such as contract duration, which determined how acute moral hazard problems were to be. Moreover,
21
22 it was precisely smaller firms the most likely to forgo the possibility of acquiring tacit knowledge.
23
24
25

26 Finally, the results obtained in this paper should also induce models that analyze contracts for
27
28 the transfer of technology to explicitly consider its temporal dimension. To the best of my knowledge,
29
30 all papers in this field consider instantaneous transfers of technology and analyze how moral hazard,
31
32 asymmetric information, or risk-sharing influence scheduled payments or the inclusion of certain
33
34 contract clauses. The fact that contracts differ in their durations has been overlooked in the literature,
35
36 and in my opinion, deserves more attention.
