PRICE CONVERGENCE IN THE EUROPEAN CAR MARKET

Salvador Gil-Pareja*

(Universidad de Valencia)

Simón Sosvilla-Rivero

(FEDEA and Universidad Complutense de Madrid)

Version: November 2005

Abstract

This paper examines price convergence in the European Union car market over the period 1995-2005. The results indicate that there is a clear evidence of price convergence among the EU15 countries, but not before 1999. Moreover, countries of the Economic and Monetary Union started convergence previously to the EU15 as a whole. Finally, exchange rate changes has significantly contributed to price dispersion over time across countries.

JEL classification numbers: F15; F30.

Key Words: Market integration, Automobiles, European Union, Euro, Exchange rates.

Simón Sosvilla-Rivero gratefully acknowledges the financial support by *Ministerio de Ciencia y Tecnología* grant SEJ2005-09094/ECON.

1. Introduction

Over the past decades, important steps have been taken in the European Union (EU) to integrate markets. One of the expected effects of the process of market integration in Europe is price convergence. This hope relies on the argument that the elimination of administrative and technical barriers to trade, as a result of the Single Market Project, and the recent adoption of the euro reduce the potential for price discrimination across member States by bolstering cross-border trade and price transparency.

There is a growing number of papers on the issues of price and inflation convergence among the EU member States (see, e. g., Camarero *et al.*, 2000; Rogers, 2001; Rogers *et al.*, 2001; Gámez-Amián and Morales-Zumaquero, 2002; Sosvilla-Rivero and Gil-Pareja, 2004; Chen, 2004; or Gil-Pareja and Sosvilla-Rivero, 2004) and the Economic and Monetary Union (EMU) countries (see, e. g., Parsley and Wei, 2001; Rogers, 2001 and 2002; Baye *et al.*, 2003, Mathä, 2003; Gajewski and Kowalski, 2004; Isgut, 2004; Engel and Rogers, 2004; or Allington *et al.*, 2005).

One market that has attracted particular interest is the European car market. A number of studies have focused on price convergence in this market (Gaulier and Haller, 2000; Lutz, 2003 and 2004; Goldberg and Verboven, 2001, 2004 and 2005). The automobile industry provides a good opportunity for studying price convergence within both EU and EMU countries. On the one hand, cross-country price differentials in the automobile industry are an important source of concern under the European Commission's competition policy. On the other hand, since May 1993, the European Commission publishes, twice a year, car price surveys for most car models sold in the EU. These surveys represent one of the rare comprehensive public sources of information on product prices in the EU at such detailed level.

The aim of this paper is to examine whether the EU15 and the eurozone car markets have become more integrated, using as a metric the dispersion of prices net of taxes. Several studies of cross-country price behaviour in the European car market have used the European Commission surveys. Our study extends those works by using a different approach to examining this data set and by incorporating the most recent information. In particular, unlike previous studies we use the concept of σ -convergence to individual car models and our data set includes 13 post-EMU and 7 post-euro price surveys.

Moreover, since the European Monetary System (EMS) represented an intermediary step to the EMU, fostering economic integration and economic policy coordination in the EU, we devote particular attention to the convergence of prices experienced by countries whose currencies participated in the core of EMS. In this regard, it has been claimed that international trade in a regime of relatively fixed exchange rates such as that established by EMS would result in price convergence. Therefore, by analysing price dispersion among EMS countries with different degrees of exchange rate stability we hope to shed new light on the success of this exchange rate agreement in terms of imposing price discipline among its members.

The paper is organised as follows. Section 2 shortly discusses economic incentives and institutions generating deviations from the law of one price. Section 3 presents the data and Section 4 sets out the empirical findings. Finally, Section 5 offers some concluding remarks.

2. The law of one price and the European car market

Much work in international economics has focused on testing the validity of the law of one price across countries. There are two versions of the law of one price: the

1
2
3 absolute and the relative versions. The absolute version states that, in the absence of
4 transfer costs and under competitive conditions, identical tradable goods priced in a
5 common currency should be equal across countries. The intuition is that international
6 arbitrage should work until prices are aligned. In its relative form, the law of one price
7 asserts that common currency prices for a particular product should change in the same
8 way over time in different countries and, therefore, it is compatible with the existence of
9 a stable price differential across markets.
10
11
12
13
14
15
16
17
18

19
20 Most of the empirical literature on the law of one price examines the validity of
21 its relative version for two main reasons. First, arbitrage is not costless. Trading between
22 locations itself has costs (such as transportation costs and trade barriers), so prices are
23 very unlikely to be identical across locations. However, these costs may give rise to a
24 stable price differential across markets. Second, the preference for testing the relative
25 version is a consequence of data limitations rather than research interest. Typically, the
26 data employed in price comparisons is in the form of price indices in different countries
27 whose levels are arbitrary. However, in this paper, the price information is based on
28 recommended retail prices of specific car models. The prices used are in ECUs/euros,
29 net of taxes and have been adjusted for equipment differences. It allows us to focus on
30 the analysis of the convergence to the absolute version of the law of one price.

36
37
38
39
40
41
42
43
44
45
46

47 Two conditions are necessary for the existence of international price differences
48 beyond transfer costs. First, firms must have market power as well as some profit
49 incentives to set different prices in different countries. Different demand elasticities,
50 import quotas, or an incomplete pass-through (of taxes or exchange rates) are the most
51 frequently studied sources of markup differences across countries in the European car
52 market and, therefore, of international price discrimination. Second, firms must be able
53 to prevent arbitrage. Traditionally, several non-tariff barriers, such as the type approval
54
55
56
57
58
59
60

1
2
3 or the national registration, have contributed to keep European car markets
4
5 geographically segmented. Despite the removal of a great part of the barriers within the
6
7 EU in 1993, some obstacles to cross-border trade have remained since then. In
8
9 particular, during the sample period the major obstacle to cross-border trade stems from
10
11 the selective and exclusive distribution system authorised by Regulation 123/85 (from
12
13 1985 to 1995) and 1475/95 (from 1995 up to 30 September 2002). This distribution
14
15 system aimed to restrict sales of new cars in the EU to dealers chosen by manufacturers,
16
17 becoming very difficult for independent wholesalers to buy cars in bulk in one country
18
19 and resell them in another. An important liberalization of the distribution system was
20
21 introduced in 2002 with transitions periods of at least one year.¹

30 **3. Data**

31
32 The price data used in this study come from the biannual surveys of car price
33
34 differentials between EU member States carried out by the European Commission since
35
36 1993. The methodology used has remained the same for all the surveys over the period
37
38 1993-2005. About 17 European and 8 Japanese manufacturers submit the recommended
39
40 retail prices on 1 May and 1 November of each year of their top-selling products. The
41
42 number of car models included in these surveys ranges from 72 to 91. The prices are
43
44 adjusted for equipment differences and are given in local currency and in ECU/euros,
45
46 both before and after tax. It shall be noted that actual retail prices may differ from
47
48 recommended list prices, as dealers are free to set their own prices. In particular, the
49
50 data set on pre-tax list prices used in this study consists of the surveys conducted over
51
52 the period from May 1995 to May 2005 (21 bi-annual surveys). The countries covered
53

60 ¹ See Goldberg and Verboven (2004) for a detailed discussion about both the profit incentives for price discrimination in the car market and the European institutions that have made international price discrimination feasible in this industry.

1
2
3 are all the EU-15 Member States.² The car models considered are those with appropriate
4 data in the range of countries and periods for the purposes of this paper. As a result, we
5
6 have selected a sample of 45 models.
7
8
9

10 11 12 13 **4. Empirical results** 14

15
16 There are various ways of measuring price dispersion, for example, the range of
17 minimum price to maximum price, the ratio of maximum price to minimum price, the
18 ratio of maximum price to mean price, the standard deviation, or the coefficient of
19 variation. We use the coefficient of variation (the ratio of the standard deviation to the
20 mean) as a measure of price dispersion because it has advantages over the cited
21 alternative measures. The coefficient of variation is invariable to changes of scale,
22 which is useful for comparing price dispersion across products or, for a given product,
23 price dispersion over time. This affords an advantage with respect to the range and the
24 standard deviation. Moreover, although the range and max-min ratio provide a measure
25 of the *total* spread of the data, they only take into account the two extreme values of the
26 data, and, therefore, they are susceptible to considerable distortion if there is an unusual
27 extreme observation. Similarly, the max-mean ratio only considers all the observations
28 in the computation of the mean, in contrast to the coefficient of variation, which takes
29 into account each of the data observations in both the numerator (which measures the
30 average spread around the mean) and the denominator (the mean).

49
50

51
52 For the purpose of assessing price convergence in the European car market we
53 use the concept of σ -convergence.³ Thus, to measure the degree of price convergence for
54
55

56
57
58 ² The pre-tax car prices are available since May 1993 for 10 European countries (Belgium, France,
59 Germany, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Spain, the United Kingdom). Pre-tax
60 prices for Denmark and Greece are available since November 1994, while for Austria, Finland and
Sweden they are available since May 1995. Data for the ten new members of the EU (Cyprus, Czech

each car model, first, we calculate the coefficient of price variation for each bi-annual survey across the corresponding set of European markets. Then, the time series of coefficients of variation for each car model (CV_t) are regressed on a constant and a linear time trend (TIME):

$$CV_t = \alpha + \sigma TIME + u_t \quad (1)$$

where α and σ are parameters to be estimated, and u_t is the error term. If price dispersion declined steadily, we would expect the regression to yield a negative and statistically significant coefficient for the linear time trend.

Tables 1-4 present the results for the 45 car models considered in five different samples of countries. The first table presents the results for EU15. Table 2 focuses on EMU11 countries. Table 3 (“group A”) examines price convergence for EU15 countries whose currencies participated continuously in the Exchange Rate Mechanism (ERM) of the EMS from the outset maintaining broadly stable bilateral exchange rates among themselves (Austria, Belgium, Denmark, France, Germany, Luxembourg, and the Netherlands). Finally, Table 4 (“group B”) includes EU15 countries whose currencies showed considerable fluctuations in value relative to the German mark (Finland, Greece, Ireland, Italy, Portugal, Spain, Sweden, and the United Kingdom).⁴ Each table reports the estimated coefficients on the linear trend in the coefficients of variation for six periods. The first three periods (columns 1 to 3) start in 1995, ending in 1998 (the year before irrevocable exchange rates among EMU countries are fixed), 2001 (the year prior

Republic, Estonia, Latvia, Lithuania, Hungary, Malta, Poland, Slovakia, Slovenia) are not considered given that they are only available since May 2004.

³ σ -convergence occurs if the cross-sectional dispersion of a variable decreases over time.

⁴ It is interesting to note that these two groups roughly correspond to the distinction made by the European Commission (1995) between those countries whose currencies continuously participated in the ERM from its inception maintaining broadly stable bilateral exchange rates among themselves over the sample period, and those countries whose currencies either entered the ERM later or suspended its participation in the ERM, as well as fluctuating in value to a great extent relative to the Deutschmark. These two groups are also basically the same found in Jacquemin and Sapir (1996), applying multivariate analysis

1
2
3 to the introduction of the euro) and 2005 (the last year in the sample), respectively. In
4
5 column 4 we analyse price convergence over the period 1998-2005. Finally, in columns
6
7 5 and 6 this recent period is divided into two which allows us to distinguish the first
8
9 years of the EMU (when the euro did not circulate) and from that time onwards.
10
11

12
13 In general, the evidence of price dispersion trends varies both according to the
14
15 sample of countries and the periods considered. As can be observed in Table 1, during
16
17 the period 1995-1998 about only half of the estimates are negative and just 5 of them are
18
19 statistically significant at the 10% level. Furthermore, 4 of the 21 positive coefficients
20
21 reach the statistical significance. Therefore, it is not surprising that the average
22
23 coefficient of variation in 1995 (0.1008) be very similar to that found in 1998 (0.1002).
24
25 One fact that may help to explain the scarce evidence of convergence during this period
26
27 is the presence of an incomplete pass-through of exchange rates to prices. Several
28
29 studies for the automobile industry have found an incomplete degree of exchange rate
30
31 pass-through to import prices (Gross and Schmitt, 1996; Gron and Swenson, 1996;
32
33 Feenstra, *et al.*, 1996), and the existence of international price discrimination induced by
34
35 exchange rate movements (Gagnon and Knetter, 1995; Gil-Pareja, 2001; Gil-Pareja,
36
37 2003), a phenomenon termed pricing to market.⁵ Extending the period to 2001, we find
38
39 an increase in the number of negative and statistically significant coefficients, but the
40
41 distribution of positive and negative coefficients remains unchanged. However, when
42
43 we add to the sample period data from 2002 onwards, the existence of price
44
45 convergence is evident: 44 out of 45 coefficients are negative and 89% of them are
46
47
48
49
50
51
52
53
54
55

56 techniques (i.e., principal components and cluster analysis) to a wide set of structural and macroeconomic
57 indicators, to form an homogeneous group of countries.

58 ⁵ In particular, Gil-Pareja (2003) investigates pricing to market behaviour in European car markets during
59 the period 1993-1998 using also the bi-annual data provided by the European Commission surveys. He
60 concludes that local currency price stability is a strong and pervasive phenomenon across products that is
consequence, at least in part, of the existence of market segmentation and international price
discrimination, despite the completion of the *single market programme* in 1993.

1
2
3 statistically significant. A similar result emerges when we analyse price convergence
4
5 over the period 1998-2005, for which the estimated coefficients for the linear time trend
6
7 is negative in all the cases and they are statistically significant at the 1% level in 87% of
8
9 them. Splitting this period into two we find a clear evidence of price convergence in
10
11 both sub-periods although it is stronger after 2001 than from 1998 to 2001.
12
13

14
15 In comparison with the EU15, the sample of EMU11 countries (Table 2) shows a
16
17 remarkably greater number of negative coefficients during the periods 1995-1998 and
18
19 1995-2001 while for the full sample period the number of negative trends is slightly
20
21 smaller. This result suggests that EMU countries started convergence previously to the
22
23 EU as a whole, which, as noted before, does not show evidence of convergence before
24
25 1999. Moreover, the study of price convergence after that year provides broadly the
26
27 same picture than for the EU in its entity. Nonetheless, two comments are in order. First,
28
29 there is more evidence of convergence among the EU15 than among EMU countries.
30
31 This might be expected since in 1998 price dispersion was considerably smaller across
32
33 EMU countries (0.0669) than across EU member States (0.1002). Second, as was
34
35 expected the evidence of price convergence is stronger in the post-euro period.⁶ The
36
37 inclusion of Greece among the set of EMU countries leads to the same conclusions.⁷
38
39
40
41
42
43

44
45 Another important issue that is an aim of this paper is the analysis of the impact
46
47 of exchange rates on convergence patterns. To this end, we study whether EU15
48
49 countries with relatively stable, credible exchange rates prior to the EMU (group A)
50
51 showed a stronger tendency towards convergence than countries with relatively volatile
52
53
54
55
56
57

58
59 ⁶ Friberg (2001) provides theoretical support to the notion that the single currency should reduce the
60 potential for price discrimination across participating countries. He shows that a monetary union promotes market integration by reducing the option value of segmenting markets.

⁷ To economise on space, we do not report the results including Greece among the set of EMU countries, but they are available from the authors upon request.

1
2
3 exchange rates (group B)⁸. In the stable currencies group (Table 3), a small majority, 26
4 out of 45, cases show a declining trend over the period 1995-1998, although only 10 of
5 them are statistically significant at the 10% level. However, in group B (Table 4) only 6
6 estimates are negative and only one of them is statistically significant at conventional
7 levels. In contrast, in the last group 24 out of 39 positive coefficients reach the statistical
8 significance at the 10% level.⁹ The enlargement of the sample period to 2001 increases
9 the number of significant trends towards lower price dispersion in both groups, even
10 though it is worth noting that there is again more evidence of convergence in group A
11 (with 19 negative and statistically significant estimates) and that, in group B, 16 of the
12 34 positive coefficients are statistically significant. When we extend the sample period
13 to 2005, we observe significantly lower price dispersion over time in 35 (23) car models
14 in group A (B). Focussing attention on the period 1998-2005, the results indicate a
15 significant trend toward lower dispersion in both samples, but in this case it is
16 particularly intense in group B where it occurs in 42 models. As a result of these trends
17 the average coefficient of variation in 2005 in group B (0.0561) is slightly smaller than
18 in group A (0.0577). Finally, it is worth noting that the evidence that emerges after
19 splitting this period into two does not differ markedly in both groups of countries, being
20 greater the number of negative trends in the post-euro period.

48
49

50 5. Concluding remarks

51 This paper has offered empirical evidence of price convergence in one market
52 that has attracted special attention during the last decade: the European car market. In
53 particular, we have examined whether the EU15 and the eurozone car markets have
54
55
56
57
58

59
60 ⁸ See Ledesma-Rodríguez *et al.* (2005) for an empirical evaluation of the credibility of the commitment to maintain the exchange rate around a central parity in the ERM.

1
2
3 become more integrated, using a different approach to that employed in previous works
4
5 (the concept of σ -convergence to individual car models) and incorporating the most
6
7 recent information. We have also explored the effect of exchange rates on price
8
9 convergence patterns by reviewing the experience of European countries that
10
11 participated in the exchange rate stability zone with a high degree of confidence with
12
13 respect to the commitment to maintain the exchange rate around a central parity against
14
15 countries with relatively volatile exchange rates.
16
17
18

19
20 Overall, the evidence of price convergence varies both according to the sample
21
22 of countries and the periods considered. In the EU as a whole there is no tendency for
23
24 price dispersion to fall over the period 1995-1998. In contrast, from 1998 onwards the
25
26 evidence of price convergence is pervasive and stronger in the post euro period than
27
28 until 2001.
29
30

31
32 If we restrict the sample to the EMU markets, we observe significant lower price
33
34 dispersion over time since 1995. It suggests that EMU countries started convergence
35
36 previously to the EU as a whole. However, the study of price convergence after
37
38 irrevocable exchange rates were fixed provides broadly the same picture than for the EU
39
40 in its entity, being the average coefficient of variation in 2005 slightly smaller in EMU
41
42 countries.
43
44
45

46
47 Finally, exchange rate movements over the period 1995-1998 has significantly
48
49 contributed to price dispersion across countries. In particular, countries with relatively
50
51 volatile exchange rates show a tendency towards a higher price dispersion over the
52
53 period 1995-1998. However, from 1998 onwards there is a very clear evidence of lower
54
55 price dispersion over time.
56
57
58
59
60

⁹ Consistent with these trends, the average coefficient of variation in group A fall from 0.095 to 0.087 over the period 1995-1998, whereas, in group B, it increases from 0.079 to 0.108 over the same period.

PRICE CONVERGENCE IN THE EUROPEAN CAR MARKET

Salvador Gil-Pareja*
(Universidad de Valencia)

Simón Sosvilla-Rivero
(FEDEA and Universidad Complutense de Madrid)

Version: March 2006

Abstract

This paper examines price convergence in the European Union car market over the period 1995-2005. We find that there is a clear evidence of price convergence among the EU15 countries, but not before 1999. Moreover, countries of the Economic and Monetary Union (EMU) started convergence previously to the EU15 as a whole. Finally, exchange rate changes have significantly contributed to price dispersion over time across countries. The results provide significant evidence that trade liberalization and the EMU have enhanced the process of regional integration in the European automobile industry, even though there is room for further measures to promote integration.

JEL classification numbers: F15; F30.

Key Words: Market integration, Automobiles, European Union, Euro, Exchange rates.

1. Introduction

Over the past decades, important steps have been taken in the European Union (EU) to integrate markets. One of the expected effects of the process of market integration in Europe is price convergence. This hope relies on the argument that the elimination of administrative and technical barriers to trade, as a result of the Single Market Project, and the recent adoption of the euro reduce the potential for price discrimination across member States by bolstering cross-border trade and price transparency.

There is a growing number of papers on the issues of price and inflation convergence among the EU member States (see, e. g., Camarero *et al.*, 2000; Rogers, 2001; Rogers *et al.*, 2001; Gámez-Amián and Morales-Zumaquero, 2002; Sosvilla-Rivero and Gil-Pareja, 2004; Chen, 2004; or Gil-Pareja and Sosvilla-Rivero, 2004) and the Economic and Monetary Union (EMU) countries (see, e. g., Parsley and Wei, 2001; Rogers, 2001 and 2002; Baye *et al.*, 2003, Mathä, 2003; Gajewski and Kowalski, 2004; Isgut, 2004; Engel and Rogers, 2004; or Allington *et al.*, 2005). Altogether, these studies show evidence of price convergence for the EU whereas the evidence for the EMU is mixed.¹

One market that has attracted particular interest is the European car market. A number of studies have focused on price convergence in this market. Gaulier and Haller (2000), using aggregate prices constructed as averages of car prices, do not find evidence of convergence over the 1993-1999 period for 10 EU countries, and conclude that exchange rate fluctuations explain a large share of the price dispersion dynamics. Lutz (2004a) finds that there has been no tendency for average car price differentials to

¹ A recent and excellent review of the literature about price dispersion in the EU and, especially, in EMU countries is offered by Allington *et al* (2005).

1
2
3 decline during 1993-1998 on a sample of 12 EU member States. Moreover, he shows
4 that deviations from the law of one price are mainly related to factors that affect the cost
5 of arbitrage activities between markets. Lutz (2004b) employs a difference-in-difference
6 approach to prices of 17 car models in 12 EU countries over the 1995-2001 period, and
7 finds that EMU has not led to a widespread narrowing of price dispersion during the first
8 three years. Goldberg and Verboven (2001) document and explain car price dispersion
9 using data for approximately 150 models, five markets (Belgium, France, Germany,
10 Italy, and the UK) and 14 years (1980-1993). They find substantial year-to-year
11 volatility in the car price data that is to a large extent accounted by exchange rate
12 fluctuations and the incomplete response of local currency prices to these fluctuations.²
13 Goldberg and Verboven (2004) find that absolute price differentials declined over the
14 1993-2003 period and, using a difference-in-difference approach, are able to derive an
15 estimate of the monetary union's contribution to this decline of approximately 1-2 %. In
16 a later paper, Goldberg and Verboven (2005) document, for the cited five countries, that
17 cross-country price differentials for the new cars declined over the 1970-2000 period,
18 and attribute this decline to the European integration process of the 1990s.

The automobile industry provides a good opportunity for studying price convergence within both EU and EMU countries. On the one hand, cross-country price differentials in the automobile industry are an important source of concern under the European Commission's competition policy. On the other hand, since May 1993, the European Commission publishes, twice a year, car price surveys for most car models sold in the EU. These surveys represent one of the rare comprehensive public sources of information on product prices in the EU at such detailed level.

² For the automobile industry several studies have found an incomplete degree of exchange rate pass-through to import prices (Gross and Schmitt, 1996; Gron and Swenson, 1996; Feenstra, *et al.*, 1996), and

The aim of this paper is to examine whether the EU15 and the eurozone car markets have become more integrated, using as a metric the dispersion of prices net of taxes. Several studies of cross-country price behaviour in the European car market have used the European Commission surveys. Our study extends those works by using a different approach to examining this data set and by incorporating the most recent information. In particular, unlike previous studies we use the concept of σ -convergence to individual car models and our data set includes 13 post-EMU and 7 post-euro price surveys.

Moreover, since the European Monetary System (EMS) represented an intermediary step to the EMU, fostering economic integration and economic policy coordination in the EU, we devote particular attention to the convergence of prices experienced by countries whose currencies participated in the core of EMS. In this regard, it has been claimed that international trade in a regime of relatively fixed exchange rates such as that established by EMS would result in price convergence. Therefore, by analysing price dispersion among EMS countries with different degrees of exchange rate stability we hope to shed new light on the success of this exchange rate agreement in terms of imposing price discipline among its members.

The paper is organised as follows. Section 2 shortly discusses economic incentives and institutions generating deviations from the law of one price. Section 3 presents the data and Section 4 sets out the empirical findings. Finally, Section 5 offers some concluding remarks.

2. The law of one price and the European car market

the existence of international price discrimination induced by exchange rate movements (Gagnon and Knetter, 1995; Gil-Pareja, 2001; Gil-Pareja, 2003), a phenomenon termed pricing to market.

Much work in international economics has focused on testing the validity of the law of one price across countries. There are two versions of the law of one price: the absolute and the relative versions. The absolute version states that, in the absence of transfer costs and under competitive conditions, identical tradable goods priced in a common currency should be equal across countries. The intuition is that international arbitrage should work until prices are aligned. In its relative form, the law of one price asserts that common currency prices for a particular product should change in the same way over time in different countries and, therefore, it is compatible with the existence of a stable price differential across markets.

Most of the empirical literature on the law of one price examines the validity of its relative version for two main reasons. First, arbitrage is not costless. Trading between locations itself has costs (such as transportation costs and trade barriers), so prices are very unlikely to be identical across locations. However, these costs may give rise to a stable price differential across markets. Second, the preference for testing the relative version is a consequence of data limitations rather than research interest. Typically, the data employed in price comparisons is in the form of price indices in different countries whose levels are arbitrary. However, in this paper, the price information is based on recommended retail prices of specific car models. The prices used are in ECUs/euros, net of taxes and have been adjusted for equipment differences. It allows us to focus on the analysis of the convergence to the absolute version of the law of one price.

Two conditions are necessary for the existence of international price differences beyond transfer costs. First, firms must have market power as well as some profit incentives to set different prices in different countries. Different demand elasticities, import quotas, or an incomplete pass-through (of taxes or exchange rates) are the most frequently studied sources of markup differences across countries in the European car

1
2
3 market and, therefore, of international price discrimination. Second, firms must be able
4
5 to prevent arbitrage. Traditionally, several non-tariff barriers, such as the type approval
6
7 or the national registration, have contributed to keep European car markets
8
9 geographically segmented. Despite the removal of a great part of the barriers within the
10
11 EU in 1993, some obstacles to cross-border trade have remained since then. In
12
13 particular, during the sample period the major obstacle to cross-border trade stems from
14
15 the selective and exclusive distribution system authorised by Regulation 123/85 (from
16
17 1985 to 1995) and 1475/95 (from 1995 up to 30 September 2002). This distribution
18
19 system aimed to restrict sales of new cars in the EU to dealers chosen by manufacturers,
20
21 becoming very difficult for independent wholesalers to buy cars in bulk in one country
22
23 and resell them in another. An important liberalization of the distribution system was
24
25 introduced in 2002 with transitions periods of at least one year.³

33
34

35 **3. Data**

36
37 The price data used in this study come from the biannual surveys of car price
38
39 differentials between EU member States carried out by the European Commission since
40
41 1993. The methodology used has remained the same for all the surveys over the period
42
43 1993-2005. About 17 European and 8 Japanese manufacturers submit the recommended
44
45 retail prices on 1 May and 1 November of each year of their top-selling products. The
46
47 number of car models included in these surveys ranges from 72 to 91. The prices are
48
49 adjusted for equipment differences and are given in local currency and in ECU/euros,
50
51 both before and after tax. It shall be noted that actual retail prices may differ from
52
53 recommended list prices, as dealers are free to set their own prices. In particular, the
54
55
56
57
58
59
60

³ See Goldberg and Verboven (2004) for a detailed discussion about both the profit incentives for price discrimination in the car market and the European institutions that have made international price discrimination feasible in this industry.

1
2
3 data set on pre-tax list prices used in this study consists of the surveys conducted over
4
5 the period from May 1995 to May 2005 (21 bi-annual surveys). The countries covered
6
7 are all the EU-15 member States.⁴ The car models considered are those with appropriate
8
9 data in the range of countries and periods for the purposes of this paper. As a result, we
10
11 have selected a sample of 45 models.
12
13
14
15
16
17

18 **4. Empirical results**

19
20 There are various ways of measuring price dispersion, for example, the range of
21
22 minimum price to maximum price, the ratio of maximum price to minimum price, the
23
24 ratio of maximum price to mean price, the standard deviation, or the coefficient of
25
26 variation. We use the coefficient of variation (the ratio of the standard deviation to the
27
28 mean) as a measure of price dispersion because it has advantages over the cited
29
30 alternative measures. The coefficient of variation is invariable to changes of scale,
31
32 which is useful for comparing price dispersion across products or, for a given product,
33
34 price dispersion over time. This affords an advantage with respect to the range and the
35
36 standard deviation. Moreover, although the range and max-min ratio provide a measure
37
38 of the *total* spread of the data, they only take into account the two extreme values of the
39
40 data, and, therefore, they are susceptible to considerable distortion if there is an unusual
41
42 extreme observation. Similarly, the max-mean ratio only considers all the observations
43
44 in the computation of the mean, in contrast to the coefficient of variation, which takes
45
46 into account each of the data observations in both the numerator (which measures the
47
48 average spread around the mean) and the denominator (the mean).

57
58 ⁴ The pre-tax car prices are available since May 1993 for 10 European countries (Belgium, France,
59
60 Germany, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Spain, the United Kingdom). Pre-tax
prices for Denmark and Greece are available since November 1994, while for Austria, Finland and
Sweden they are available since May 1995. Data for the ten new members of the EU (Cyprus, Czech

For the purpose of assessing price convergence in the European car market we use the concept of σ -convergence.⁵ Thus, to measure the degree of price convergence for each car model, first, we calculate the coefficient of price variation for each bi-annual survey across the corresponding set of European markets. Then, the time series of coefficients of variation for each car model (CV_t) are regressed on a constant and a linear time trend (TIME):

$$CV_t = \alpha + \sigma TIME + u_t \quad (1)$$

where α and σ are parameters to be estimated, and u_t is the error term. If price dispersion declined steadily, we would expect the regression to yield a negative and statistically significant coefficient for the linear time trend.

Tables 1-4 present the results for the 45 car models considered in four different samples of countries. The first table presents the results for EU15. Table 2 focuses on EMU11 countries. Table 3 (“group A”) examines price convergence for EU15 countries whose currencies participated continuously in the Exchange Rate Mechanism (ERM) of the EMS from the outset maintaining broadly stable bilateral exchange rates among themselves (Austria, Belgium, Denmark, France, Germany, Luxembourg, and the Netherlands). Finally, Table 4 (“group B”) includes EU15 countries whose currencies showed considerable fluctuations in value relative to the German mark (Finland, Greece, Ireland, Italy, Portugal, Spain, Sweden, and the United Kingdom).⁶ Each table reports the estimated coefficients on the linear trend in the coefficients of variation for six

Republic, Estonia, Latvia, Lithuania, Hungary, Malta, Poland, Slovakia, Slovenia) are not considered given that they are only available since May 2004.

⁵ σ -convergence occurs if the cross-sectional dispersion of a variable decreases over time.

⁶ It is interesting to note that these two groups roughly correspond to the distinction made by the European Commission (1995) between those countries whose currencies continuously participated in the ERM from its inception maintaining broadly stable bilateral exchange rates among themselves over the sample period, and those countries whose currencies either entered the ERM later or suspended its participation in the ERM, as well as fluctuating in value to a great extent relative to the Deutschmark. These two groups are also basically the same found in Jacquemin and Sapir (1996), applying multivariate analysis

1
2
3 periods. The first three periods (columns 1 to 3) start in 1995, ending in 1998 (the year
4 before irrevocable exchange rates among EMU countries are fixed), 2001 (the year prior
5 to the introduction of the euro) and 2005 (the last year in the sample), respectively. In
6 column 4 we analyse price convergence over the period 1998-2005. Finally, in columns
7 5 and 6 this recent period is divided into two which allows us to distinguish the first
8 years of the EMU (when the euro did not circulated) and from that time onwards.
9
10
11
12
13
14
15
16

17
18 In general, the evidence of price dispersion trends varies both according to the
19 sample of countries and the periods considered. As can be observed in Table 1, during
20 the period 1995-1998 about only half of the estimates are negative and just 5 of them are
21 statistically significant at the 10% level. Furthermore, 4 of the 21 positive coefficients
22 reach the statistical significance. Therefore, it is not surprising that the average
23 coefficient of variation in 1995 (0.1008) be very similar to that found in 1998 (0.1002).
24 One fact that may help to explain the scarce evidence of convergence during this period
25 is the presence of an incomplete pass-through of exchange rates to prices. As noted
26 before, in the automobile industry, several studies have found an incomplete degree of
27 exchange rate pass-through to import prices (Gross and Schmitt, 1996; Gron and
28 Swenson, 1996; Feenstra, *et al.*, 1996) and evidence of pricing to market behaviour
29 (Gagnon and Knetter, 1995; Gil-Pareja, 2001; Gil-Pareja, 2003).⁷ Extending the period
30 to 2001, we find an increase in the number of negative and statistically significant
31 coefficients, but the distribution of positive and negative coefficients remains
32 unchanged. However, when we add to the sample period data from 2002 onwards, the
33
34
35
36
37
38
39
40
41

51
52
53
54
55

56 techniques (i.e., principal components and cluster analysis) to a wide set of structural and macroeconomic
57 indicators, to form an homogeneous group of countries.

58 ⁷ In particular, Gil-Pareja (2003) investigates pricing to market behaviour in European car markets during
59 the period 1993-1998 using also the bi-annual data provided by the European Commission surveys. He
60 concludes that local currency price stability is a strong and pervasive phenomenon across products that is
consequence, at least in part, of the existence of market segmentation and international price
discrimination, despite the completion of the *single market programme* in 1993.

1
2
3 existence of price convergence is evident: 44 out of 45 coefficients are negative and
4
5 89% of them are statistically significant. A similar result emerges when we analyse price
6
7 convergence over the period 1998-2005, for which the estimated coefficients for the
8
9 linear time trend is negative in all the cases and they are statistically significant at the
10
11 1% level in 87% of them. Splitting this period into two we find a clear evidence of price
12
13 convergence in both sub-periods although it is stronger after 2001 than from 1998 to
14
15 2001.
16
17
18

19
20 In comparison with the EU15, the sample of EMU11 countries (Table 2) shows a
21
22 remarkably greater number of negative coefficients during the periods 1995-1998 and
23
24 1995-2001 while for the full sample period the number of negative trends is slightly
25
26 smaller.⁸ This result suggests that EMU countries started convergence previously to the
27
28 EU as a whole, which, as noted before, does not show evidence of convergence before
29
30 1999. Moreover, the study of price convergence after that year provides broadly the
31
32 same picture than for the EU in its entity. Nonetheless, two comments are in order. First,
33
34 there is more evidence of convergence among the EU15 than among EMU countries.
35
36 This might be expected since in 1998 price dispersion was considerably smaller across
37
38 EMU countries (0.0669) than across EU member States (0.1002). Second, as was
39
40 expected the evidence of price convergence is stronger in the post-euro period.⁹ The
41
42 inclusion of Greece among the set of EMU countries leads to the same conclusions.¹⁰
43
44
45
46
47
48

49 Another important issue that is an aim of this paper is the analysis of the impact
50
51 of exchange rates on convergence patterns. To this end, we study whether EU15
52
53
54

55
56 ⁸ The result for the period 1995-2001 contrast with Lutz (2004b)'s conclusions on a sample of 17 car
57
58 models.

59 ⁹ Friberg (2001) provides theoretical support to the notion that the single currency should reduce the
60
potential for price discrimination across participating countries. He shows that a monetary union promotes
market integration by reducing the option value of segmenting markets.

¹⁰ To economise on space, we do not report the results including Greece among the set of EMU countries,
but they are available from the authors upon request.

1
2
3 countries with relatively stable and credible exchange rates prior to the EMU (group A)
4
5 showed a stronger tendency towards convergence than countries with relatively volatile
6
7 exchange rates (group B)¹¹. In the stable currencies group (Table 3), a small majority, 26
8
9 out of 45, cases show a declining trend over the period 1995-1998, although only 10 of
10
11 them are statistically significant at the 10% level. However, in group B (Table 4) only 6
12
13 estimates are negative and only one of them is statistically significant at conventional
14
15 levels. In contrast, in the last group 24 out of 39 positive coefficients reach the statistical
16
17 significance at the 10% level.¹² The enlargement of the sample period to 2001 increases
18
19 the number of significant trends towards lower price dispersion in both groups, even
20
21 though it is worth noting that there is again more evidence of convergence in group A
22
23 (with 19 negative and statistically significant estimates) and that, in group B, 16 of the
24
25 34 positive coefficients are statistically significant. When we extend the sample period
26
27 to 2005, we observe significantly lower price dispersion over time in 35 (23) car models
28
29 in group A (B). Focussing attention on the period 1998-2005, the results indicate a
30
31 significant trend toward lower dispersion in both samples, but in this case it is
32
33 particularly intense in group B where it occurs in 42 models. As a result of these trends
34
35 the average coefficient of variation in 2005 in group B (0.0561) is slightly smaller than
36
37 in group A (0.0577). Finally, it is worth noting that the evidence that emerges after
38
39 splitting this period into two does not differ markedly in both groups of countries, being
40
41 greater the number of negative trends in the post-euro period.

5. Concluding remarks

59 ¹¹ See Ledesma-Rodríguez *et al.* (2005) for an empirical evaluation of the credibility of the commitment
60 to maintain the exchange rate around a central parity in the ERM.

¹² Consistent with these trends, the average coefficient of variation in group A fall from 0.095 to 0.087 over the period 1995-1998, whereas, in group B, it increases from 0.079 to 0.108 over the same period.

34

This paper has offered empirical evidence of price convergence in one market that has attracted special attention during the last decade: the European car market. In particular, we have examined whether the EU15 and the eurozone car markets have become more integrated, using a different approach to that employed in previous works (the concept of σ -convergence to individual car models) and incorporating the most recent information. We have also explored the effect of exchange rates on price convergence patterns by reviewing the experience of European countries that participated in the exchange rate stability zone with a high degree of confidence with respect to the commitment to maintain the exchange rate around a central parity against countries with relatively volatile exchange rates. Even though the differences in the samples of countries and periods considered in previous studies calls for caution in comparing the results, our findings are, in general, consistent with the evidence reported in the introductory material.

60

Overall, the evidence of price convergence varies both according to the sample of countries and the periods considered. In the EU as a whole there is no tendency for price dispersion to fall over the period 1995-1998. In contrast, from 1998 onwards the evidence of price convergence is pervasive and stronger once the euro has replaced the national currencies of the member countries than until 2001. If we restrict the sample to the EMU markets, we observe significant lower price dispersion over time since 1995. It suggests that EMU countries started convergence previously to the EU as a whole. However, the study of price convergence after irrevocable exchange rates were fixed provides broadly the same picture than for the EU in its entity, being the average coefficient of variation in 2005 slightly smaller in EMU countries (0.048 against 0.057 in the EU15). Finally, exchange rate movements over the period 1995-1998 has significantly contributed to price dispersion across countries. In particular, countries

1
2
3 with relatively volatile exchange rates show a tendency towards a higher price
4 dispersion over the period 1995-1998. However, from 1998 onwards there is a very
5
6 clear evidence of lower price dispersion over time.
7
8
9

10 We view our results as evidence that the progress towards integration in Europe,
11 and especially the formation of the EMU, has had visible effects on cross-country price
12 dispersion in recent years even though price convergence has not yet been completed.
13 The findings in this paper have important policy implications. First, the comparison
14 between countries with different degrees of exchange rate stability, as well as the
15 evidence that price differentials become smaller before across EMU countries than
16 across EU15 members, has implications for the role of exchange rate policy on price
17 dispersion. Both suggest that exchange rate stability has contributed to market
18 integration beyond the role of other integration measures. Second, since the evidence of
19 price convergence is stronger in the post-euro period not only for the EMU members but
20 also for the EU15, the decline in price dispersion cannot be attributed, at least only, to
21 the euro. Finally, to the extent that, despite the evidence of convergence, price
22 differences across EMU countries remain significant after four years from the
23 introduction of the euro, additional measures to promote integration (such as tax
24 harmonization) are needed to achieve full integration of the European car markets.

Notes: * significant at 10%, ** significant at 5%, *** significant at 1%. Each trend is the coefficient estimate of biannual price dispersion (measured as the coefficient of variation) regressed on a time trend. The regressions include a constant. Group A includes: Austria, Belgium, Denmark, France, Germany, Luxembourg, and the Netherlands.
