Abstract

This paper proposes and estimates an inflation indicator for the European Monetary Union (EMU). This indicator is set up so that it is contemporarily not affected by the changes in price differentials among EMU countries. The results show that the Monetary Union Index of Consumer Prices (MUICP), which is the inflation measure that the European Central Bank (ECB) takes as a reference for monetary policy purposes, could be understating the value of the inflation in the euro zone. It is also concluded that regional peculiarities are fundamental in the evolution of prices in the different EMU countries.

1. Introduction

Since January 1999 a broad spectrum of European countries have a common currency: the euro. The European Monetary Union (EMU) is constituted by 12 countries (Belgium, Germany, Greece, Spain, France, Ireland, Italy, the Netherlands, Austria, Portugal, Finland and Luxembourg) each with its economic peculiarities but all of them with a common monetary policy conducted by the European Central Bank (ECB). The Treaty on European Union assigns the Eurosystem the primary objective of maintaining price stability in the euro area. The ECB has quantified this objective in terms of the Monetary Union Index of Consumer Prices (MUICP), which on a medium term should have an annual increase of below 2%.

In this context, with a common monetary policy focussing on price stability and with a very specific inflation objective, there has recently been a great interest in establishing good indicators of inflation in the euro area as alternatives to the MUICP. Efforts have mainly been devoted to the construction of reliable inflation indicators, and in particular to the setting up of what is usually known as core inflation indexes whose evolution is not distorted by transitory changes in the relative prices of goods that are unrelated to the medium-run objectives of central bankers (see, for example, Cristadoro et al., 2001, Bagliano et al., 2002 and Vega and Wynne, 2003).

The aim of this work is to propose a simple indicator of inflation in the euro zone from a different perspective. The idea is that a good inflation indicator of a monetary region should not be affected by asymmetric shocks in prices in different union members nor by the idiosyncratic effects of a common shock. A good euro zone inflation indicator

1
2
3 should not be affected by changes in price differentials between countries. Taking this
4
5 as a point of departure, a decomposition of the price variations in each country into two
6
7 components is suggested, one common to all the countries and the other idiosyncratic.
8
9 The common component is the inflation indicator proposed in this work. Its advantage
10
11 is that it is very simple to estimate and interpret.
12
13
14
15
16

17 In addition to this introduction the article contains three other sections. The second
18
19 section describes the statistical framework in which the inflation indicator is defined.
20
21 The third section presents the empirical results. The paper ends with a section of
22
23 conclusions.
24

27
28

29 **2. A very simple framework for the analysis of inflation in the EMU**

30
31
32
33
34 The approach to the problem of inflation measurement is purely statistical and very
35
36 simple. In a monetary region like the euro zone, let us assume that the variations in
37
38 prices of the goods in each country j at a moment t , denominated by
39
40 $\pi_{jt} = \nabla \text{Ln}(P_{jt}) = \text{Ln}(P_{jt}) - \text{Ln}(P_{jt-1})$, have two components, one common to all the
41
42 countries in the monetary region and the other idiosyncratic. The common component,
43
44 denoted by π_t^* , measures the generalized rise in all the prices of goods denominated in
45
46 euros. The idiosyncratic component, denoted by π_{jt}^{**} , reflects the specific evolution of
47
48 prices in each country, due for example to asymmetric shocks in the prices of one or
49
50 several goods or to the idiosyncratic effects of a common shock. Thus:
51
52
53
54
55
56
57
58
59
60

$$\pi_{jt} = \pi_t^* + \pi_{jt}^{**} \quad \forall j = 1, \dots, n \quad (1)$$

Both components are relevant from an economic policy perspective. π_t^* , as a measure of the generalized rise in all the prices of goods denominated in euros, can be a good inflation indicator for monetary policy purposes. π_{jt}^{**} , as it reflects the specific evolution of prices in each country, permits to analyse which part of the changes in prices in each country is independent of the ECB monetary policy.

π_t^* and π_{jt}^{**} are unobservable, but identification strategies can be proposed for both components. In this work we propose a very simple identification strategy: if π_t^* and π_{jt}^{**} are assumed to be orthogonal, π_t^* will also be orthogonal to $d_{jii} = \pi_{jt} - \pi_{it} = \pi_{jt}^{**} - \pi_{it}^{**}$ $j \neq i$ $j, i = 1, \dots, n$. It is important to point out that $d_{jii} = \pi_{jt} - \pi_{it}$, which is observable, only contains information on idiosyncratic movements of prices in the different countries. So, for instance, an autonomous shock in the prices of a country, j , would not be reflected in π_t^* but they would in π_{jt}^{**} , which would cause a variation in $d_{jii} = \pi_{jt} - \pi_{it}$. This suggests that a measurement of π_t^* can be constructed, exploiting its independence of the observable components $d_{jii} = \pi_{jt} - \pi_{it}$.

A proposal for the identification of the common component

We propose an identification strategy for the common component π_t^* based on the information contained in π_{jt} :

$$\pi_t^* = \sum_{j=1}^n \alpha_j \pi_{jt} \text{ where } \sum_{j=1}^n \alpha_j = 1 \quad j = 1, 2, \dots, n \quad t = 1, 2, \dots, T$$

Such that:

$$Cov\left[\nabla \pi_t^* \left(\nabla \pi_{jt} - \nabla \pi_{it}\right)\right] = 0 \quad \forall j \neq i \quad j, i = 1, 2, \dots, n \quad t = 1, 2, \dots, T \quad (2)$$

The orthogonality conditions are imposed in the first differences given the non stationary character usually presented by the variation rates of prices in the different countries (see, for example, Ribba, 2003, Marques et al., 2002, Freeman, 1998, Mishkin, 1984, and Schwert, 1987).

Note that equation (2) gives $(n-1) \times (n-1)$ orthogonality conditions, $(n-1) \times (n-2)$ of them being redundant. So that (2) can be expressed as:

$$Cov\left[\nabla \pi_t^* \left(\nabla \pi_{1t} - \nabla \pi_{it}\right)\right] = 0 \quad \forall i = 2, 3, \dots, n \quad t = 1, 2, \dots, T \quad (3)$$

The variations in π_t^* are contemporarily independent of the variations in $(\pi_{1t} - \pi_{it})$ which are a function of the price differentials in the different countries. It is in this sense that π_t^* is independent of the price differentials between countries and constitutes the common component.

One advantage of this way of identifying π_t^* is that its estimation becomes very simple.

The weights can be estimated by Least Squares from the following regression model:

$$\nabla \pi_{1t} = \alpha_2 \left(\nabla \pi_{1t} - \nabla \pi_{2t}\right) + \alpha_3 \left(\nabla \pi_{1t} - \nabla \pi_{3t}\right) + \dots + \alpha_n \left(\nabla \pi_{1t} - \nabla \pi_{nt}\right) + u_t \quad (4)$$

in which $\nabla \pi_t^* = u_t$ y $\nabla \pi_{jt}^{**} = \nabla \pi_{jt} - \nabla \pi_t^*$ $j = 1, 2, \dots, n$ $t = 1, 2, \dots, T$.

Once the common component has been identified it can be of interest to decompose the mean value of π_{jt} ($\bar{\pi}_j$) into two components, the mean value of the common component and the mean value of the idiosyncratic component. From (1):

$$\bar{\pi}_j = \bar{\pi}^* + \bar{\pi}_j^{**} \quad \forall j = 1, \dots, n \quad (5)$$

It is also possible to analyse which part of the variance of $\nabla \pi_{jt}$ comes from the common component and which part comes from the idiosyncratic one. Taking equations (1) and (2) we can break down the variance of $\nabla \pi_{jt}$ into two components, one related to the changes in $\nabla \pi_{jt}^{**} = \nabla \pi_{jt} - \nabla \pi_t^*$ and another to the changes in $\nabla \pi_t^*$. So that:

$$\text{var}(\nabla \pi_{jt}) = \text{var}(\nabla \pi_{jt} - \nabla \pi_t^*) + \text{var}(\nabla \pi_t^*) \quad (6)$$

3. The empirical analysis

The data employed in the analysis come from the Eurostat database and cover the period between January 1999, the time at which the EMU was officially constituted, and August, 2004. Two possible price indicators were considered for each country: the Harmonized Index of Consumer Prices (HICP), and the component “All items excluding energy and unprocessed food” from the HICP (HICPEEUF), which is usually used as a core inflation indicator. To minimize the effect of seasonality we have used

1
2
3
4 year-on-year variation rates, defined as: $\nabla_{12} \text{Ln}(HICP_{jt}) = \text{Ln}(HICP_{jt}) - \text{Ln}(HICP_{jt-12})$
5
6
7 and $\nabla_{12} \text{Ln}(HICPEEU_{jt}) = \text{Ln}(HICPEEU_{jt}) - \text{Ln}(HICPEEU_{jt-12})$.
8
9

10
11
12 Figures 1 and 2 show the evolution of these rates. The different evolution of these
13
14 inflation measurements suggests the existence of important idiosyncratic factors in the
15
16 determination of prices in each country in the euro zone. Another element worth
17
18 pointing out is the non stationary character of the series, which, as already indicated,
19
20 has been taken into account in the formulation of the theoretical framework in the
21
22 previous section. Unit roots tests are presented in the Appendix for the series
23
24 $\nabla_{12} \text{Ln}(HICP_{jt})$ and $\nabla_{12} \text{Ln}(HICPEEU_{jt})$ which show their I(1) character.
25
26
27
28
29
30
31

32
33 The HICP's of the EMU member countries are aggregated to set up an inflation
34
35 indicator for the whole of the euro zone, the MUICP. In this indicator each country has
36
37 a weight obtained from the share of each country's household final monetary
38
39 consumption in the relevant total. The MUICP plays a key role in the design of the
40
41 monetary policy of the euro area by the ECB, which has defined its objective of price
42
43 stability as an annual increase in the MUICP of below 2% to be maintained over the
44
45 medium term. Similarly to the MUICP, another aggregate inflation indicator for the
46
47 euro area is obtained from the HICPEEU of each country. The HICPEEU of the euro
48
49 zone is frequently used as an indicator of the core inflation in that monetary area.
50
51
52
53

54
55
56 Given the decisive role they play in the monitoring and control of EMU prices, it would
57
58 seem to be relevant to analyse if the MUICP and the HICPEEU of the euro zone
59
60 inflations could constitute measures of the common component described in the

1
2
3 previous section, which reflects the generalized rise in all the prices of goods
4 denominated in euros. It is easy to verify that they could not. Table 1 presents, as an
5 illustration, the correlation coefficients between the variations in $\nabla_{12} \text{Ln}(MUICP)$ and
6 the variations in some of the differentials between countries in $\nabla_{12} \text{Ln}(HICP_{jt})$. It also
7 presents the correlation coefficients between the variations in $\nabla_{12} \text{Ln}(HICPEEU F)$ of
8 the euro area and the variations in some of the differentials between countries in
9 $\nabla_{12} \text{Ln}(HICPEEU F_{jt})$. It can be seen that many of the correlations exceed 0.25 in
10 absolute value, which suggests that neither the MUICP nor the HICPEEU F of the euro
11 zone are independent of the price differentials between countries, so that any
12 idiosyncratic shock in the prices of any country affects those indicators.
13

27
28
29
30
31

32 Table 2 shows the results of the estimation of equation (4), from which the weights of
33 each country in the common component are obtained. The equation has been estimated
34 both with HICP and HICPEEU F data. For a large number of countries the weights were
35 not statistically significant at usual significance levels, neither individually nor jointly¹,
36 so that restricted estimations of equation (4) are also presented. Also, as data starting
37 from 1999 was being used, structural change tests were carried out in the weights in
38 January 2001, when Greece was incorporated into the EMU. The results show that,
39 either with the HICP data or with those of the HICPEEU F, the hypothesis of the
40 absence of a structural change cannot be rejected².
41
42

55
56
57

58 ¹ With the HICP data a Wald test was carried out of the hypothesis of joint significance of the weights of
59 Belgium, Greece, Spain, France, Ireland, Luxembourg, Austria and Finland obtaining a p-value of 0.577.
60 For the HICPEEU F data a test was made for the weights of Greece, Spain, Luxembourg, Austria and
Portugal obtaining a p-value of 0.165.

² With the HICP data the p-value obtained was 0.621 and with the HICPEEU F data it was 0.587.

1
2
3 Figure 3 shows the evolution of $\nabla_{12} \text{Ln}(MUICP)$ and of the estimated common
4 component of the HICP's, obtained both from the restricted and from the unrestricted
5 estimations of equation (4). Likewise, Figure 4 presents the evolution of the
6 $\nabla_{12} \text{Ln}(HICPEEUF)$ of the euro zone together with its corresponding common
7 components. In both cases it can be observed that there are no great differences between
8 the common component calculated from the unrestricted and restricted models.
9
10
11
12
13
14
15
16
17
18
19

20 As can be seen, in both cases the common components are almost always above
21 $\nabla_{12} \text{Ln}(MUICP)$ and $\nabla_{12} \text{Ln}(HICPEEUF)$ of the euro zone, which suggests that these
22 measurements could be underestimating the inflation of the euro area. To be specific,
23 the average of $\nabla_{12} \text{Ln}(MUICP)$ for the period considered is 20% lower than that of the
24 corresponding common components³ and that of the $\nabla_{12} \text{Ln}(HICPEEUF)$ of the euro
25 zone is 15% lower⁴.
26
27
28
29
30
31
32
33
34
35
36
37

38 It is also useful to calculate for each country, from equation (5), the contribution of its
39 corresponding idiosyncratic component to the average of $\nabla_{12} \text{Ln}(HICP)$ and of
40 $\nabla_{12} \text{Ln}(HICPEEUF)$, shown in Table 3. It should be highlighted the importance of the
41 idiosyncratic components in usual inflation measures. Especially notable is the case of
42 Germany, with a negative contribution to the average of the idiosyncratic component,
43 and that of Ireland with a positive contribution.
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58

59 ³The average of $\nabla_{12} \text{Ln}(MUICP)$ is 0.020 and for both common components 0.025.

60 ⁴ The average of $\nabla_{12} \text{Ln}(HICPEEUF)$ of the euro-zone is 0.017 compared to 0.020 for both common components.

1
2
3 It is also of interest to use the equation (6) to break down the variances of the variations
4 in $\nabla_{12} \text{Ln}(HICP)$ and in $\nabla_{12} \text{Ln}(HICPEEUF)$ for each country in that part related to the
5 common component and that related to the idiosyncratic component. The results are
6 shown in Table 4⁵. It can again be seen that the idiosyncratic components have a great
7 weight in the variance of the inflation measurements based on the HICP or on the
8 HICPEEUF, exceeding 55% for all countries. For the euro area, the variations in the
9 common component are only responsible for 42-43% of the variations in inflation
10 measured with the MUICP or with the HICPEEUF, which is evidence on the limitations
11 of these variables as measurements of the common component.

27 **4. Conclusions**

28
29
30
31
32 The aim of this work has been to propose a simple inflation indicator for the euro zone.
33 An inflation indicator was set up with changes contemporarily orthogonal to the
34 variations in the inflation differentials between countries. In this sense, the inflation
35 indicator constructed is not affected by the effects of asymmetric shocks in prices in the
36 different countries. Its objective is to reflect the generalized rise in all the prices of
37 goods denominated in euros.
38

51
52
53
54
55
56
57
58
59
60

The variations in the prices of the different countries can be broken down into two
components: the common component, which is the inflation indicator proposed, and the
idiosyncratic component. With data from the 12 EMU countries, both components were
estimated and compared with two other current euro area inflation measurements
(MUICP and HICPEEUF). It was concluded that the MUICP, which is the indicator that

⁵ Note that the estimated variances for the variations in the common component are the same in the

1
2
3 the ECB takes as a reference for its monetary policy, could be understating the true rate
4 of inflation in the euro zone. To be specific, for the period between 1999 and 2004, this
5 undervaluation could be around 20%. The same happened with the HICPEEUF.
6
7
8
9

10
11
12 Another relevant conclusion is that the idiosyncratic components have a great weight in
13 the usual inflation measurements used in each of the different countries in the euro
14 zone, both in terms of the average and in terms of the variance. This suggests that, in
15 spite of the unified monetary policy, regional peculiarities continue to be fundamental
16 in the evolution of prices in the different EMU countries.

Abstract

This paper proposes and estimates an inflation indicator for the European Monetary Union (EMU). This indicator is set up so that it is contemporarily not affected by the changes in price differentials among EMU countries. The results show that the Monetary Union Index of Consumer Prices (MUICP), which is the inflation measure that the European Central Bank (ECB) takes as a reference for monetary policy purposes, could be understating the value of the inflation in the euro zone. It is also concluded that regional peculiarities are fundamental in the evolution of prices in the different EMU countries.

1. Introduction

Since January 1999 a broad spectrum of European countries have a common currency: the euro. The European Monetary Union (EMU) is constituted by 12 countries (Belgium, Germany, Greece, Spain, France, Ireland, Italy, the Netherlands, Austria, Portugal, Finland and Luxembourg) each with its economic peculiarities but all of them with a common monetary policy conducted by the European Central Bank (ECB). The Treaty on European Union assigns the Eurosystem the primary objective of maintaining price stability in the euro area. The ECB has quantified this objective in terms of the Monetary Union Index of Consumer Prices (MUICP), which on a medium term should have an annual increase of below 2%.

In this context, with a common monetary policy focussing on price stability and with a very specific inflation objective, there has recently been a great interest in establishing good indicators of inflation in the euro area as alternatives to the MUICP. Efforts have mainly been devoted to the construction of reliable inflation indicators, and in particular to the setting up of what is usually known as core inflation indexes whose evolution is not distorted by transitory changes in the relative prices of goods that are unrelated to the medium-run objectives of central bankers (see, for example, Quah and Vahey, 1995, Bjornland, 2001, Bagliano et al., 2002, Bagliano and Morana, 2003, Vega and Wynne, 2003, Marques et al. 2003 and Cristadoro et al., 2005).

The aim of this work is to propose a simple indicator of inflation in the euro zone from a different perspective. The idea is that a good inflation indicator of a monetary region should not be affected by asymmetric shocks in prices in different union members nor

1
2
3 by the idiosyncratic effects of a common shock. A good euro zone inflation indicator
4 should not be affected by changes in price differentials between countries. Taking this
5
6
7
8 as a point of departure, a decomposition of the price variations in each country into two
9
10 components is suggested, one common to all the countries and the other idiosyncratic.
11
12 The common component is the inflation indicator proposed in this work. Its advantage
13
14
15 is that it is very simple to estimate and interpret.
16
17
18
19

20 In addition to this introduction the article contains three other sections. The second
21
22 section describes the statistical framework in which the inflation indicator is defined.
23
24 The third section presents the empirical results. The paper ends with a section of
25
26 conclusions.
27
28
29
30
31

32 **2. A very simple framework for the analysis of inflation in the EMU**

33
34
35

36 The approach to the problem of inflation measurement is purely statistical and very
37
38 simple. In a monetary region like the euro zone, let us assume that the variations in
39
40 prices of the goods in each country j at a moment t , denominated by
41
42 $\pi_{jt} = \nabla \text{Ln}(P_{jt}) = \text{Ln}(P_{jt}) - \text{Ln}(P_{j(t-1)})$, have two components, one common to all the
43
44 countries in the monetary region and the other idiosyncratic. The common component,
45
46 denoted by π_t^* , measures the generalized rise in all the prices of goods denominated in
47
48 euros. The idiosyncratic component, denoted by π_{jt}^{**} , reflects the specific evolution of
49
50 prices in each country, due for example to asymmetric shocks in the prices of one or
51
52 several goods or to the idiosyncratic effects of a common shock. Thus:
53
54
55
56
57
58
59
60

$$\pi_{jt} = \pi_t^* + \pi_{jt}^{**} \quad \forall j = 1, \dots, n \quad (1)$$

Both components are relevant from an economic policy perspective. π_t^* , as a measure of the generalized rise in all the prices of goods denominated in euros, can be a good inflation indicator for monetary policy purposes. π_{jt}^{**} , as it reflects the specific evolution of prices in each country, permits to analyse which part of the changes in prices in each country is independent of the ECB monetary policy.

π_t^* and π_{jt}^{**} are unobservable, but identification strategies can be proposed for both components. In this work we propose a very simple identification strategy: if π_t^* and π_{jt}^{**} are assumed to be orthogonal, π_t^* will also be orthogonal to $d_{jii} = \pi_{jt} - \pi_{it} = \pi_{jt}^{**} - \pi_{it}^{**}$ $j \neq i$ $j, i = 1, \dots, n$. It is important to point out that $d_{jii} = \pi_{jt} - \pi_{it}$, which is observable, only contains information on idiosyncratic movements of prices in the different countries. So, for instance, an autonomous shock in the prices of a country, j , would not be reflected in π_t^* but they would in π_{jt}^{**} , which would cause a variation in $d_{jii} = \pi_{jt} - \pi_{it}$. This suggests that a measurement of π_t^* can be constructed, exploiting its independence of the observable components $d_{jii} = \pi_{jt} - \pi_{it}$.

A proposal for the identification of the common component

We propose an identification strategy for the common component π_t^* based on the information contained in π_{jt} :

$$\pi_t^* = \sum_{j=1}^n \alpha_j \pi_{jt} \text{ where } \sum_{j=1}^n \alpha_j = 1 \quad j = 1, 2, \dots, n \quad t = 1, 2, \dots, T$$

Such that:

$$\text{Cov}\left[\nabla \pi_t^* \left(\nabla \pi_{jt} - \nabla \pi_{it}\right)\right] = 0 \quad \forall j \neq i \quad j, i = 1, 2, \dots, n \quad t = 1, 2, \dots, T \quad (2)$$

The orthogonality conditions are imposed in the first differences given the non stationary character usually presented by the variation rates of prices in the different countries (see, for example, Charemza et al. 2005, Ribba, 2003, Marques et al. 2003, Marques et al., 2002, Freeman, 1998, Mishkin, 1984, and Schwert, 1987).

Note that equation (2) gives $(n-1) \times (n-1)$ orthogonality conditions, $(n-1) \times (n-2)$ of them being redundant. So that (2) can be expressed as:

$$\text{Cov}\left[\nabla \pi_t^* \left(\nabla \pi_{1t} - \nabla \pi_{it}\right)\right] = 0 \quad \forall i = 2, 3, \dots, n \quad t = 1, 2, \dots, T \quad (3)$$

The variations in π_t^* are contemporarily uncorrelated with the variations in $(\pi_{1t} - \pi_{it})$ which are a function of the price differentials in the different countries. It is in this sense that π_t^* is independent of the price differentials between countries and constitutes the common component.

One advantage of this way of identifying π_t^* is that its estimation becomes very simple.

The weights can be estimated by Least Squares from the following regression model:

$$\nabla \pi_{1t} = \alpha_2(\nabla \pi_{1t} - \nabla \pi_{2t}) + \alpha_3(\nabla \pi_{1t} - \nabla \pi_{3t}) + \dots + \alpha_n(\nabla \pi_{1t} - \nabla \pi_{nt}) + u_t \quad (4)$$

in which $\nabla \pi_t^* = u_t$ and $\nabla \pi_{jt}^{**} = \nabla \pi_{jt} - \nabla \pi_t^* \quad j = 1, 2, \dots, n \quad t = 1, 2, \dots, T$.

Once the common component has been identified it can be of interest to decompose the mean value of π_{jt} ($\bar{\pi}_j$) into two components, the mean value of the common component and the mean value of the idiosyncratic component. From (1):

$$\bar{\pi}_j = \bar{\pi}^* + \bar{\pi}_j^{**} \quad \forall j = 1, \dots, n \quad (5)$$

It is also possible to analyse which part of the variance of $\nabla \pi_{jt}$ comes from the common component and which part comes from the idiosyncratic one. Taking equations (1) and (2) we can break down the variance of $\nabla \pi_{jt}$ into two components, one related to the changes in $\nabla \pi_{jt}^{**} = \nabla \pi_{jt} - \nabla \pi_t^*$ and another to the changes in $\nabla \pi_t^*$. So that:

$$\text{var}(\nabla \pi_{jt}) = \text{var}(\nabla \pi_{jt} - \nabla \pi_t^*) + \text{var}(\nabla \pi_t^*) \quad (6)$$

3. The empirical analysis

The data employed in the analysis come from the Eurostat database and cover the period between January 1999, the time at which the EMU was officially constituted, and August, 2004. Two possible price indicators were considered for each country: the Harmonized Index of Consumer Prices (HICP), and the component “All items

1
2
3 excluding energy and unprocessed food” from the HICP (HICPEEUF), which is usually
4 used as a core inflation indicator. To minimize the effect of seasonality we have used
5
6
7
8 year-on-year variation rates, defined as:

$$9 \quad \nabla_{12} \text{Ln}(HICP_{jt}) = \text{Ln}(HICP_{jt}) - \text{Ln}(HICP_{j(t-12)})$$

$$10 \quad \text{and } \nabla_{12} \text{Ln}(HICPEEUF_{jt}) = \text{Ln}(HICPEEUF_{jt}) - \text{Ln}(HICPEEUF_{j(t-12)}).$$

51
52
53
54
55
56
57
58
59
60

Figures 1 and 2 show the evolution of these rates. The different evolution of these inflation measurements suggests the existence of important idiosyncratic factors in the determination of prices in each country in the euro zone. Another element worth pointing out is the non stationary character of the series, which, as already indicated, has been taken into account in the formulation of the theoretical framework in the previous section. Unit roots tests are presented in the Appendix for the series $\nabla_{12} \text{Ln}(HICP_{jt})$ and $\nabla_{12} \text{Ln}(HICPEEUF_{jt})$ which show their I(1) character.

The HICP's of the EMU member countries are aggregated to set up an inflation indicator for the whole of the euro zone, the MUICP. In this indicator each country has a weight obtained from the share of each country's household final monetary consumption in the relevant total. The MUICP plays a key role in the design of the monetary policy of the euro area by the ECB, which has defined its objective of price stability as an annual increase in the MUICP of below 2% to be maintained over the medium term. Similarly to the MUICP, another aggregate inflation indicator for the euro area is obtained from the HICPEEUF of each country. The HICPEEUF of the euro zone is frequently used as an indicator of the core inflation in that monetary area.

1
2
3 Given the decisive role they play in the monitoring and control of EMU prices, it would
4 seem to be relevant to analyse if the MUICP and the HICPEEUF of the euro zone
5 inflations could constitute measures of the common component described in the
6 previous section, which reflects the generalized rise in all the prices of goods
7 denominated in euros. It is easy to verify that they could not. Table 1 presents, as an
8 illustration, the correlation coefficients between the variations in $\nabla_{12}Ln(MUICP)$ and
9 the variations in some of the differentials between countries in $\nabla_{12}Ln(HICP_{jt})$. It also
10 presents the correlation coefficients between the variations in $\nabla_{12}Ln(HICPEEUF)$ of
11 the euro area and the variations in some of the differentials between countries in
12 $\nabla_{12}Ln(HICPEEUF_{jt})$. It can be seen that many of the correlations exceed 0.25 in
13 absolute value and are statistically significant at the 5% level, which suggests that
14 neither the MUICP nor the HICPEEUF of the euro zone are uncorrelated with the price
15 differentials between countries, so that any idiosyncratic shock in the prices of any
16 country affects those indicators.

33
34
35
36
37
38
39
40

41 Table 2 shows the results of the estimation of equation (4), from which the weights of
42 each country in the common component are obtained. The equation has been estimated
43 both with HICP and HICPEEUF data. For a large number of countries the weights were
44 not statistically significant at usual significance levels, neither individually nor jointly¹,
45 so that restricted estimations of equation (4) are also presented. Also, as data starting
46 from 1999 was being used, structural change tests were carried out in the weights in
47 January 2001, when Greece was incorporated into the EMU. The results show that,
48
49
50
51
52
53
54
55
56
57
58

59 ¹ With the HICP data a Wald test was carried out of the hypothesis of joint significance of the weights of
60 Belgium, Greece, Spain, France, Ireland, Luxembourg, Austria and Finland obtaining a p-value of 0.577.
For the HICPEEUF data a test was made for the weights of Greece, Spain, Luxembourg, Austria and
Portugal obtaining a p-value of 0.165.

1
2
3 either with the HICP data or with those of the HICPEEUF, the hypothesis of the
4 absence of a structural change cannot be rejected².
5
6
7
8
9

10 Figure 3 shows the evolution of $\nabla_{12}Ln(MUICP)$ and of the estimated common
11 component of the HICP's, obtained both from the restricted and from the unrestricted
12 estimations of equation (4). Likewise, Figure 4 presents the evolution of the
13 $\nabla_{12}Ln(HICPEEUF)$ of the euro zone together with its corresponding common
14 components. In both cases it can be observed that there are no great differences between
15 the common component calculated from the unrestricted and restricted models.
16
17
18
19
20
21
22
23
24
25
26

27 As can be seen, in both cases the common components are almost always above
28 $\nabla_{12}Ln(MUICP)$ and $\nabla_{12}Ln(HICPEEUF)$ of the euro zone, which suggests that these
29 measurements could be underestimating the inflation of the euro area. To be specific,
30 the average of $\nabla_{12}Ln(MUICP)$ for the period considered is 20% lower than that of the
31 corresponding common components³ and that of the $\nabla_{12}Ln(HICPEEUF)$ of the euro
32 zone is 15% lower⁴.
33
34
35
36
37
38
39
40
41
42
43
44

45 It is also useful to calculate for each country, from equation (5), the contribution of its
46 corresponding idiosyncratic component to the average of $\nabla_{12}Ln(HICP)$ and of
47 $\nabla_{12}Ln(HICPEEUF)$, shown in Table 3. It should be highlighted the importance of the
48 idiosyncratic components in usual inflation measures. Especially notable is the case of
49
50
51
52
53
54
55
56
57

58 ² With the HICP data the p-value obtained was 0.621 and with the HICPEEUF data it was 0.587.

59 ³ The average of $\nabla_{12}Ln(MUICP)$ is 0.020 and for both common components 0.025.

60 ⁴ The average of $\nabla_{12}Ln(HICPEEUF)$ of the euro-zone is 0.017 compared to 0.020 for both common components.

1
2
3 Germany, with a negative contribution to the average of the idiosyncratic component,
4
5 and that of Ireland with a positive contribution.
6
7
8
9

10 It is also of interest to use the equation (6) to break down the variances of the variations
11
12 in $\nabla_{12} \text{Ln}(HICP)$ and in $\nabla_{12} \text{Ln}(HICPEEUf)$ for each country in that part related to the
13
14 common component and that related to the idiosyncratic component. The results are
15
16 shown in Table 4⁵. It can again be seen that the idiosyncratic components have a great
17
18 weight in the variance of the inflation measurements based on the HICP or on the
19
20 HICPEEUf, exceeding 55% for all countries. For the euro area, the variations in the
21
22 common component are only responsible for 42-43% of the variations in inflation
23
24 measured with the MUICP or with the HICPEEUf, which is evidence on the limitations
25
26 of these variables as measurements of the common component.

34 **4. Conclusions**

35
36 The aim of this work has been to propose a simple inflation indicator for the euro zone.
37
38 An inflation indicator was set up with changes contemporarily orthogonal to the
39
40 variations in the inflation differentials between countries. In this sense, the inflation
41
42 indicator constructed is not affected by the effects of asymmetric shocks in prices in the
43
44 different countries. Its objective is to reflect the generalized rise in all the prices of
45
46 goods denominated in euros.
47
48
49
50
51
52
53

54
55 The variations in the prices of the different countries can be broken down into two
56
57 components: the common component, which is the inflation indicator proposed, and the
58
59
60

1
2
3 idiosyncratic component. With data from the 12 EMU countries, both components were
4
5 estimated and compared with two other current euro area inflation measurements
6
7 (MUICP and HICPEEUF). It was concluded that the MUICP, which is the indicator that
8
9 the ECB takes as a reference for its monetary policy, could be understating the true rate
10
11 of inflation in the euro zone. To be specific, for the period between 1999 and 2004, this
12
13 undervaluation could be around 20%. The same happened with the HICPEEUF.
14
15
16
17
18
19

20 Another relevant conclusion is that the idiosyncratic components have a great weight in
21
22 the usual inflation measurements used in each of the different countries in the euro
23
24 zone, both in terms of the average and in terms of the variance. This suggests that, in
25
26 spite of the unified monetary policy, regional peculiarities continue to be fundamental in
27
28 the evolution of prices in the different EMU countries.
29
30
31
