25 **Abstract:** Does aggressive use of discretionary fiscal policy induce macroeconomic
26 instability in terms of higher output and inflation volatility? Three main conclusions arise
27 from our cross-section and panel analysis for a sample of 20 OECD countries: First,
28 discretionary fiscal policy has a significant and sizeable effect on volatility of GDP (per
29 capita) and all of its components. Second, there is no direct effect on inflation volatility; since
30 output volatility is an important determinant of inflation volatility, however, discretionary
31 fiscal policy indirectly exacerbates inflation volatility. These results turn out robust with
32 respect to alternative fiscal policy measures and endogeneity concerns. Finally, many of the
33 fiscal rules introduced since 1990 appear to have reduced the use of discretionary fiscal
34 policy.

I. Introduction

Over the last 15 years many OECD countries introduced fiscal rules. The European Union's Maastricht criteria of 1992, which were extended to the Stability and Growth Pact in 1997, represent only the most prominent case among numerous changes in the fiscal policy framework. This move towards 'rules rather than discretion' reflects a fundamental shift in the paradigm of fiscal policy. Not only is it widely accepted now that monetary policy is a superior tool for macroeconomic stabilization policy (see Romer and Romer, 1994); it is also widely believed today that tying the government's hand by a proper design of fiscal rules can help to improve fiscal policy outcomes. Two main arguments are usually put forward to support this view: First, to prevent governments from running excessive deficits and from conducting unsustainable policies; second, to limit the room for discretionary policy in order to improve macroeconomic stability. The latter argument, which is the main subject of this study, is based on the assumption that aggressive use of fiscal policy induces instabilities in terms of higher output volatility (Fatas and Mihov, 2003a) or higher inflation volatility (Rother, 2004). The detrimental effects may go beyond the welfare costs of instability per se which are widely viewed to be negligible since Lucas (1987). Fatas and Mihov (2003a) find a negative relation between output volatility and long-run growth; and it was already Friedman (1977) to argue that inflation volatility is harmful to growth. If discretionary fiscal policy in fact lowered output growth by inducing higher volatility the welfare gains from restricting fiscal policy discretion could be sizeable (Barlevy, 2004).

Whether fiscal policy should be left unrestricted or bound by rule, and how such an optimal rule would look like, are questions of obvious policy relevance. The widespread disagreement in the debate on the reform (abolishment) of the EU's Stability and Growth Pact does not only reflect alternative ideological positions but also bears witness that the academic debate on a proper framework for fiscal policy is far from settled. Before firm

1
2
3 recommendations can be derived, however, it is a prerequisite that the effects of discretionary
4
5 fiscal policy have been clarified unambiguously.
6

7
8 This paper investigates, as carefully and comprehensively as possible, the link between
9
10 discretionary fiscal policy and macroeconomic stability in terms of output and inflation
11
12 volatility. It goes beyond previous studies by investigating the effect on GDP components
13
14 separately, checking the robustness of the results with respect to alternative measures of fiscal
15
16 policy, and by using both a cross-section approach (based on annual data) and a panel
17
18 approach (based on quarterly data). Endogeneity concerns are addressed in two different
19
20 ways: in the cross section estimation, we use (mainly time-invariant) institutional variables
21
22 suggested by Fatas and Mihov (2003a) as instruments; in the panel analysis we use the system
23
24 GMM approach suggested by Blundell and Bond (1998). Finally, we also provides a first,
25
26 tentative assessment, whether the fiscal rules introduced by OECD countries over the last 15
27
28 years have indeed led to a significant reduction in the use of discretionary fiscal policy.
29
30

31
32 The topic of this paper is related closely to a strand of literature that investigates the
33
34 evolution of output volatility over time and the sources of business cycle volatility. A number
35
36 of studies has noticed that the volatility of the growth rate in real output appears to have fallen
37
38 in OECD countries over the past decade, particularly compared with the 1970s (see Blanchard
39
40 and Simon (2001), McConnell and Perez-Quiros (2000), Stock and Watson (2002) for the US,
41
42 Buch, Döpke and Pierdzioch (2004), Fritsche and Kuzin (2005) for Germany, Debs (2001) for
43
44 Canada, Buckle, Haugh and Thomson (2001) for New Zealand and Simon (2001) for
45
46 Australia). Regarding the sources of output volatility, Cecchetti, Flores-Lagunes, and Krause
47
48 (2005) argue that improvements in inventory management, monetary policy, financial
49
50 innovation, international openness and smaller shocks, all played a role in determining a
51
52 widespread fall in output volatility across OECD countries. This paper adds to this strand of
53
54 literature by investigating the causal link between fiscal policy and output volatility and
55
56
57
58
59
60

1
2
3 whether a change in the use of discretionary fiscal policy over time has also contributed to the
4
5 shift in output volatility across countries.
6

7 We find destabilizing effects of discretionary fiscal policy on GDP per capita and its
8
9 components. In contrast, we do not find a direct effect on inflation volatility. Since the
10
11 volatility of output (of the output gap) turns out to be an important determinant of inflation
12
13 volatility, however, discretionary fiscal policy exerts an indirect effect on inflation volatility.
14
15 It is worth emphasizing, how robust the results turn out against alternative measures and
16
17 estimation methods. Finally, most rules introduced by OECD countries over the last 15 years
18
19 appear to have reduced the use of discretionary fiscal policy.
20
21
22

23 The remainder of the paper is organized as follows. Section II estimates and compares
24
25 various measures of discretionary fiscal policy. Sections III and IV investigate the effects of
26
27 discretionary fiscal policy on the volatility of GDP (and its components) and the volatility of
28
29 inflation, using both a cross-section and a panel approach. Section V presents some stylized
30
31 facts on the effects of the fiscal rules that have been introduced in several OECD countries in
32
33 the 1990s. The final section VI summarizes the results and concludes.

37

38 **II. Measuring discretionary fiscal policy**

39 *1. Methodological issues*

40
41
42 There is no consensus in the literature on how to construct a measure of a government's fiscal
43
44 stance. The first question is how broadly fiscal policy should be defined. Fatas and Mihov
45
46 (2003a) consider the expenditure side only, using the narrowest measure (government
47
48 consumption). Blanchard and Perotti (2002), who study the effects of tax and spending shocks
49
50 in a structural VAR approach, include government investment in their expenditure measure.
51
52 Gali and Perotti (2003), in their investigation of the consequences of the Stability and Growth
53
54 Pact for counter-cyclical fiscal policy in EU Member States, focus on the primary budget
55
56
57
58
59
60

1
2
3 deficit (They also consider primary spending and revenues separately). A priori, none of these
4
5 measures is superior. On the one hand, expenditures are less responsive to the cycle than
6
7 receipts and hence less vulnerable to endogeneity concerns with respect to GDP than revenues
8
9 or the budget. On the other hand, omitting taxes and other receipts may give an incomplete
10
11 measure of the fiscal stance; this is particularly true if a tax cut is financed by a decrease in
12
13 expenditures, or, *mutatis mutandis*, in the case of a tax financed expenditure programme. The
14
15 ultimate choice will not only depend much on the question of interest, but will also be dictated
16
17 by the availability of (budget) data. Focussing on OECD countries enables us to pursue a
18
19 comprehensive approach and to check the robustness of the results obtained with alternatively
20
21 defined variables (all of them in real terms): i) government consumption (*GC*); ii) government
22
23 spending, i.e. consumption and investment (*GS*); iii) total primary spending, i.e. total
24
25 disbursements excl. interest payments (*EXP*); iv) total primary receipts, i.e. total receipts excl.
26
27 interest receipts (*REC*); and v) the primary balance or net lending ($NL = REC - EXP$).
28
29
30
31

32 Irrespective of which variable is used, it is of crucial importance to distinguish cyclical
33
34 movements (e.g. in the budget deficit) from discretionary changes in fiscal policy. Following
35
36 the notion of Galí and Perotti (2003), the *cyclical component* may also be termed *endogenous*
37
38 *component* of the budget; it is that part of the budget that is driven by forces which are largely
39
40 outside the control of fiscal authorities (at least in the short-run); unemployment benefits are a
41
42 case in point. The *structural component*, representing discretionary changes by the policy
43
44 makers, may in turn be decomposed into two parts: an *endogenous structural component*,
45
46 which reflects discretionary policy measures taken in response to the state of the economy
47
48 (such as counter-cyclical fiscal policy) and an *exogenous structural component*, reflecting
49
50 discretionary policy measures unrelated to the state of the economy, i.e. pure fiscal shocks.
51
52 Henceforth, 'discretionary fiscal policy' is always meant to represent this exogenous
53
54 structural component.
55
56
57
58
59
60

One approach to decomposing fiscal policy is to partial out business cycle effects in a regression of the fiscal policy measure on variables related to the state of the economy; the residuals, i.e. that part of the variables unexplained by the state of the economy, may then be interpreted as exogenous structural component. This is the approach suggested by Fatas and Mihov (2003a). In particular, they use the following regression

$$\Delta \ln GC_{i,t} = \alpha_i + \gamma_i \Delta \ln GC_{i,t-1} + \beta_i \Delta \ln Y_{i,t} + \delta_i \mathbf{W}_{i,t} + \varepsilon_{i,t}^{GC} \quad (1)$$

where GC is (real) government consumption, Y is real GDP, and \mathbf{W} is a matrix of controls (inflation, squared inflation, and a time trend). Since Y and GC are likely to be determined simultaneously, $\Delta \ln Y_{i,t}$ is instrumented using all other right hand side variables plus two lags of output growth ($\Delta \ln Y_{i,t-1}$, $\Delta \ln Y_{i,t-2}$), and the natural log of the average crude oil price. This regression is run separately for each of the i countries; t denotes the time period which differs from country to country due to data availability. Fatas and Mihov (2003a) interpret the error term ($\varepsilon_{i,t}^{GC}$) as discretionary fiscal shock and view its volatility over a certain time period ($\sqrt{\text{Var}(\varepsilon_{i,t}^{GC})}$) – the typical size of a change in discretionary policy – as indicator of the aggressiveness of a government's discretionary fiscal policy. They use a large cross-section of countries and consider government consumption (GC) only, but their approach can be easily extended to the other fiscal variables mentioned above, i.e. government spending (GS), primary spending (EXP) and primary receipts (REC). For the primary deficit (NL), which can also take negative values, however, we modify equation (1), taking the absolute difference (in per cent of GDP) rather than the log difference as dependent variable. The interpretation of the residuals remains the same, now relating to the deficit, however.

An alternative approach is to start from a cyclically adjusted measure of the fiscal variable as calculated by several organizations (OECD, EU Commission, IMF). Together with a hypothesis on how policy makers conduct fiscal policy (a fiscal rule) the structural measure can be further decomposed into its endogenous and exogenous component. The advantage of

1
2
3 this approach is that it yields a complete decomposition of the fiscal measure into all three
4
5 components. There are some drawbacks, however: First it relies on cyclically adjusted
6
7 measures, which requires an estimate of potential GDP. The second is that one has to specify
8
9 a fiscal rule; a government's fiscal behaviour, however, may be hard to summarize with a
10
11 simple equation. Finally, cyclically adjusted measures are unavailable for several countries.
12
13 This approach was suggested by Gali and Perotti (2003), who investigate the consequence of
14
15 the EU's Stability and Growth Pact on fiscal policy, particularly on the room for
16
17 countercyclical fiscal policy. Their empirical model is
18
19

$$20 \quad NLA_{i,t} = \alpha_i + \gamma_i NLA_{i,t-1} + \beta_i GAP_{i,t}^e + \delta_i D_{i,t} + v_{i,t}^{NLA} \quad (2)$$

21
22 where $NLA_{i,t}$ is the cyclically *adjusted*, primary deficit (calculated by the OECD), expressed
23
24 in per cent of potential output; a positive value of the parameter in front of the expected
25
26 output gap (GAP^e), defined as the deviation of actual from potential output in per cent of
27
28 potential output, is associated with the conduct of counter-cyclical fiscal policy. The debt
29
30 level (D) is included as control variable, reflecting the presumption that a higher level of debt
31
32 leaves less room for manoeuvre. Finally, the lagged dependent variable is included to take up
33
34 the serial correlation in the residuals, which may reflect a partial adjustment process to the
35
36 target level of the adjusted deficit.¹ Again the residuals are interpreted as exogenous
37
38 component of the structural deficit; by definition, the predicted values then represent the
39
40 endogenous structural component, which – by least squares properties – have the convenient
41
42 property of being orthogonal to the exogenous component. Apart from the use of a cyclically
43
44 adjusted dependent variable, there are two further differences to aforementioned approach in
45
46 (1): equation (2) is specified in levels rather than in absolute differences of the primary deficit
47
48
49
50
51
52

53
54
55 ¹ As mentioned by Gali and Perotti, equation (2) can also be interpreted as reduced form of a structural model,
56
57 where governments have a target level of the debt-GDP ratio and there are costs of changing the structural deficit
58
59 over time (see Ballabriga and Martinez-Mongay (2002)).
60

1
2
3 and the dependent variable is expressed in per cent of potential rather than actual output. In
4
5 order to make the estimates for the primary deficit comparable to that obtained using model
6
7 (1) (i.e. the Fatas and Mihov (2003a) approach), we will take first differences of the residuals.
8
9 Rescaling our measure in per cent of actual rather than potential output changes the results
10
11 only trivially, such that we dispense from making this transformation. Finally, to make (2)
12
13 estimable, we follow Gali and Perotti (2002): the expected output gap is replaced by its actual
14
15 value and instrumented using the lagged output gap and the lagged output gap of the USA; for
16
17 the USA the lagged output gap of the EU is used as second instrument.²
18
19

20 21 22 23 *2. Estimation*

24
25 Previous studies used annual data and focussed on selected measures; often, these restrictions
26
27 were due to the use of large cross section of countries. Our approach is to focus on selected
28
29 OECD countries which allows us i) to give a comprehensive assessment based on various
30
31 measures of fiscal policy using an annual data set, and ii) to extend the previous studies to a
32
33 panel approach using a quarterly data set. Accordingly, we will split the discussion of the
34
35 results into two parts.
36
37
38
39
40

41 42 *2.1 Analysis using annual data*

43
44 Depending on the measure used, the number of countries ranges from 18 to 20; the length of
45
46 the time series varies across countries. Table A1 in the appendix gives a detailed overview of
47
48 the samples for the alternative measures. Model (1) was then estimated for each country i ,
49

50
51 ² Since (2) is interpreted as fiscal rule, and the first-stage regression as forecast function of the policy maker for
52
53 the output gap, we use the second-stage residuals (rather than the structural residuals) of the IV estimation as
54
55 measure of fiscal shocks. This is also required to obtain orthogonality between the endogenous structural
56
57 component (i.e. the second-stage predicted values from (2)) and the exogenous structural component (i.e. the
58
59 second-stage residuals from (2)).
60

using five alternative dependent variables: government consumption (GC), government spending (GS), total primary spending (EXP), total primary receipts (REC), all of them in real terms³ and log differences, and the primary deficit (NL) in absolute differences expressed in per cent of GDP. For each country i , this yields five alternative time series reflecting exogenous fiscal shocks: $e_{i,t}^{GC}$, $e_{i,t}^{GS}$, $e_{i,t}^{EXP}$, $e_{i,t}^{REC}$, and $e_{i,t}^{NL}$; the typical size of these shocks, i.e. the measure of the aggressiveness of fiscal policy, is obtained by taking the standard deviation of these time series, yielding five variables per country: σ_i^{GC} , σ_i^{GS} , σ_i^{EXP} , σ_i^{REC} , and σ_i^{NL} .

Model (2) was also estimated for each country i , using the cyclically adjusted primary deficit, expressed in per cent of potential output, as dependent variable (NLA). For each country i , this yields us an additional time series of fiscal shocks, which was differenced ($\Delta v_{i,t}^{NLA}$) to make it comparable with the measures above; taking the standard deviation again, we obtain σ_i^{NLA} as sixth alternative measure of the aggressiveness of fiscal policy.

It is of interest in itself to compare the various measures of discretionary fiscal policy. Table 1 shows the correlation between the country-specific standard deviations of the exogenous, structural component of the alternative fiscal variables.⁴

< Table 1 here >

Considering first the measures constructed with the Fatas and Mihov (2003a) approach (i.e. model (1)), we observe that the three expenditure-based measures (σ_i^{GC} , σ_i^{GS} , σ_i^{EXP}) are highly correlated; thus the size and frequency of changes in government consumption appear to reflect a government's behaviour with respect to the overall expenditure side well.

³ For total primary spending (EXP), total primary receipts (REC), and the primary deficit (NL) the GDP deflator was used to convert the nominal figures into real terms.

⁴ Notice that the time periods from which the country-specific standard deviations are calculated differ somewhat across countries as a result of data availability (see Appendix A1). The results are hardly affected, however, if overlapping time periods are used.

Moreover, the variability of primary spending and revenues are highly correlated as well (0.836); thus governments with an active expenditure policy do on average also pursue an active tax policy. This is also reflected in the correlation between the variability of spending or revenues with the budget (0.712 and 0.624 respectively). Comparing the deficit-based measures obtained with the Fatas and Mihov (2003a) and the Gali and Perotti (2003) approach, i.e. σ_i^{NL} with σ_i^{NLA} , the correlations is 0.720. This suggests that the two approaches deliver broadly comparable results.

2.1 Analysis using quarterly data

The use of quarterly data (or higher frequency data) is a natural choice when investigating volatility issues. The problem here is that budget data are unavailable at a quarterly level (or derived by mechanical interpolations); for several countries, quarterly data on government investment is missing as well. Hence, the gain from increasing in observation comes at the cost of a reduction in the available measures of fiscal policy. In our quarterly analysis we consider only government consumption (GC), which is available for 18 countries. Based on the evidence from the annual analysis, however, it is not implausible to assume that our measure based on government consumption (GC) can be regarded as representative. Again, Table A1 in the Appendix gives a detailed overview of the quarterly sample.

As before we estimate equation (1) using the log difference of government consumption (GC) as dependent variable. In the baseline specification, using just one lag, we find strong serial correlation in the residuals. Removing the serial correlation is important for two reasons: From an econometric perspective, serial correlation in the presence of a lagged dependent variable yields inconsistent estimates. From an economic perspective, the presence of serial correlation conflicts with the interpretation of the residuals as exogenous shocks. Hence, we extended the lag structure of model (1), adding lags two to four of the dependent

1
2
3 variable as explanatory variable; additionally we included one lag of GDP growth (extending
4
5 the instruments up to lag five accordingly). This removes the correlation from all 18 series
6
7 except that of Spain and the United Kingdom ($e_{ESP,t}^{GC}$ $e_{GBR,t}^{GS}$). Explicit adjustment for
8
9 autocorrelation using the corresponding AR-terms leads to residual series for these two
10
11 countries, which are highly correlated with the original series, so that – for the sake of
12
13 consistency – we use the same model as for the other countries.
14
15

16
17 A further point is worth noting: White tests of the residuals indicate the presence of
18
19 heteroscedasticity in most series (for 12 of the 18 series the White-test is significant and for 3
20
21 further series close to the 10 per cent level). This suggests that it is in fact worthwhile to
22
23 pursue a panel approach to exploit not only the cross-country variation, but also the within-
24
25 country variation of the series of fiscal shocks in order to infer something about their effects
26
27 on macroeconomic stability.
28
29

30 31 32 **III. Fiscal policy and output volatility**

33
34 Having obtained several alternative measures of fiscal policy we now go on to provide an
35
36 assessment of the effect of fiscal policy on output volatility. We first consider the cross-
37
38 section estimates using annual data; then we turn to the panel estimates using quarterly data.
39
40 To give a first impression of the variation in the data, Figure 1 shows a scatter plot of one of
41
42 our fiscal measures (σ_i^{GS}) against output volatility.
43
44
45

46
47 < Figure 1 here >
48
49

50 51 *1. Cross section analysis*

52
53 We depart from the baseline model by Fatas and Mihov (2003a); thereby, output volatility,
54
55 defined as standard deviation of the growth rate of output per capita ($\sigma_i^{\Delta \ln y}$), is regressed on
56
57 the standard deviation of the fiscal policy measure (σ_i^{FP}) and several control variables (**W**):
58
59
60

$$\ln \sigma_i^{\Delta \ln y} = \alpha + \gamma \ln \sigma_i^{FP} + \delta \mathbf{W}_i + \varepsilon_i \quad (3)$$

Three controls are added: government size (*GSIZE*) to account for the government's potentially stabilizing role emphasized by Galí (1994); the log of real GDP per capita (*GDP p.c.*), since poorer countries may more often resort to discretionary policy; finally, trade is included as standard control for output volatility as argued by Rodrik (1998).

Two variables in (3) are likely to be correlated with the error term: the fiscal policy measure (σ_i^{FP}), while constructed in a very careful way, may be still due in part to output volatility; moreover, it is likely to be subject to measurement error. Government size (*GSIZE*) might be endogenous as well; as argued by Rodrik (1998), more volatile economies may have an incentive to set up larger governments. We thus estimate our models using both least squares and instruments to ensure that our results are not contaminated by endogeneity of the regressors.

The volatility of fiscal policy (σ_i^{FP}) is instrumented using the institutional variables suggested by Fatas and Mihov (2003a; zero-one dummies for majoritarian (*MAJ*) and presidential (*PRES*) regimes, a measure of political constraints (*PCON*), and the number of elections (*NEL*)); as additional instrument, we add the degree of fiscal decentralisation, measured in terms of the share of sub-national government expenditures in general government expenditures net of intergovernmental transfers (FD^{EXP}).⁵ The theoretical underpinning of these instruments is taken from the growing literature on institutions and economic policy (see, for example, Person and Tabellini (2000)) and discussed more in detail by Fatas and Mihov (2003a). As far as government size (*GSIZE*) is concerned, we follow the standard approach in the literature and use the dependency ratio (*DEP*), the urbanization rate

⁵ For the revenue based measure of fiscal policy, fiscal decentralisation in terms of revenues was used (FD^{REV}); for the deficit measures, both FD^{EXP} and FD^{REV} were included as instruments.

1
2
3 (*URB*), and the log of population (*POP*) as (additional) instruments. A detailed description of
4
5 the variables and the data sources is given in the Appendix.
6

7 Fatas and Mihov (2003a) consider government consumption as measure of fiscal policy
8 only. We estimate model (3) using all five measures of fiscal policy derived above in order to
9
10 check the robustness of the results with respect to alternatively defined measures of fiscal
11
12 policy. As a consequence of data availability (particularly budget data and cyclically adjusted
13
14 data) the cross-section dimension i is very low; hence, the panel analysis using quarterly data,
15
16 which is pursued below, is an important complement to the cross-section estimates, which are
17
18 shown in Table 2.
19
20
21

22
23 < Table 2 >
24

25
26 Several points are worth emphasizing: First, the coefficient using government consumption
27
28 (*GC*) as fiscal measure (0.428) is de facto identical to that obtained by Fatas and Mihov
29
30 (2003a) for their subsample of 25 OECD countries (0.490). Second, it is astonishing, how
31
32 robust the findings turn out against the use of alternative measures of fiscal policy. We always
33
34 find a significant impact of fiscal policy on output volatility, whether expenditure-based, tax-
35
36 based or budget-based measures are used; it also makes no difference, which of the two
37
38 approaches to estimate the budget-based measure (model (1) or (2)) is pursued. Third, the null
39
40 of valid instruments cannot be rejected by any of the tests of overidentifying restrictions;
41
42 notice that the IV estimates of γ are always higher, which points to an attenuation bias of the
43
44 least squares estimates as a result of measurement error.
45
46
47

48 The coefficients of the fiscal variables are also economically significant. It is clearly
49
50 unrealistic to assume that the volatility of discretionary fiscal policy could be reduced to zero.
51
52 But it is not implausible to assume that the scope for reducing the volatility of fiscal policy
53
54 (σ_i^{FP}) amounts to one and a half times the standard deviation of σ_i^{FP} across countries (on
55
56 average this is less than 40 per cent of the difference between the maximum and minimum
57
58
59
60

1
2
3 value of σ_i^{FP}). According to our estimates this would reduce output volatility by some 27 per
4
5 cent on average; depending on the fiscal measure used the attainable reduction ranges from 22
6
7 to 35 per cent.
8
9

10 It could be objected that the results in Table 2 (and that of Fatas and Mihov (2003a))
11
12 have some tautological flavour. Particularly, government consumption (GC) and government
13
14 spending (GS) are part of GDP; hence their volatilities will normally be correlated with that of
15
16 GDP. However, essentially the same results are obtained, if the dependent variable is replaced
17
18 by the volatility of ‘private GDP’ per capita, i.e. GDP excluding government spending (GS) or
19
20 excluding government consumption (GC) when GC is used as fiscal measure. The detailed
21
22 results are given in Table A2 in the Appendix. Here we go one step further and re-estimate
23
24 equation (3), using the volatility of consumption, investment, exports, and imports (all in per
25
26 capita terms) as dependent variable. Table 3 shows the results using the net lending measure
27
28 (σ_i^{NL}) as fiscal variable, but as in the previous regressions, the results may be regarded as
29
30 representative for the other fiscal variables as well.
31
32
33
34

35 < Table 3 >
36
37

38 We find a significant destabilizing effect of fiscal policy on all GDP components except
39
40 exports. This buttresses the results obtained so far and implies that aggressive use of
41
42 discretionary fiscal policy does not only amplify business cycles by adding noise to the output
43
44 series but that fiscal shocks are propagated through the whole economy and spill over to
45
46 private sector output components as well.⁶
47
48

49 An important qualification to the results obtained so far is the small number of
50
51 observations. We will thus extend our analysis to a panel approach based on quarterly data in
52
53 the next section. An important message to carry over to the subsequent quarterly analysis,
54
55 which uses only government consumption (GC) as a measure of fiscal policy for reasons of
56
57

58
59 ⁶ A similar point, though referring to counter-cyclical fiscal policy, was already made by Friedman (1953).
60

1
2
3 data availability, is that the results are extremely robust against using alternative measures of
4
5 fiscal policy. Thus we may reasonably regard the results for GC as representative.
6
7

8 9 2. Panel analysis

10
11 Using quarterly data has considerable appeal for our question of interest. Using higher
12
13 frequency data is a natural choice, when investigating volatility issues. Moreover, the
14
15 extension to a panel approach not only allows us to increase the degrees of freedom but also
16
17 to control for country- and time-specific effects, which – if correlated with the regressors
18
19 (instruments) – would render our estimates inconsistent. The heteroscedasticity in the series of
20
21 fiscal shocks, i.e. in the residuals of model (1) using GC (see section II), indicates that there is
22
23 significant within-country variation, which is worth being exploited in a panel approach. As a
24
25 compromise to the inherent trade-off between generating a sufficient number of observations
26
27 and choosing sufficiently long subperiods, we split up our sample into non-overlapping 4 year
28
29 intervals. Hence, model (3) becomes
30
31
32
33

$$34 \ln \sigma_{i,t}^{\Delta \ln y} = \alpha_i + \gamma \ln \sigma_{i,t}^{GC} + \delta \mathbf{W}_{i,t} + \eta_t + \varepsilon_{i,t}, \quad (4)$$

35
36 where α_i are the country-specific and η_t are the time-specific fixed effects. The cross-section
37
38 dimension i comprises 18 countries; depending on data availability, the country-specific time
39
40 dimension T_i ranges from 4 to 11 (quadrennial) observations, i.e. we have an unbalanced
41
42 panel. As already mentioned above, government consumption is used as only measure of
43
44 fiscal policy in the quarterly analysis for reasons of data availability.
45
46
47
48

49
50 As in our cross section analysis it is important to check the results from the least squares
51
52 dummy variable estimates (LSDV) with respect to the exogeneity assumption. Moving to a
53
54 panel, however, has important implications for the choice of instruments for the fiscal policy
55
56 variable ($\sigma_{i,t}^{GC}$): The institutional variables become useless; no variation over time (as in MAJ
57
58 and $PRES$) or extremely low variation over time (in $POLCON$, $NOELEC$, FD^{EXP} , FD^{EXP})
59
60

1
2
3 make them de facto perfectly collinear with the country-specific fixed effects. Hence, we will
4
5 adopt a less structural approach, exploiting the (testable) assumption that lags of the
6
7 endogenous regressors may be used as instruments. An approach that has gained wide
8
9 acceptance to address endogeneity concerns in a panel framework is the generalized method
10
11 of moments (GMM) estimator suggested by Blundell and Bond (1998): Thereby a combined
12
13 system of the equations in levels and in first differences is estimated; in the levels equations
14
15 lags of the first difference of the endogenous variable are used as instruments; in the equations
16
17 in first differences, lagged levels are used as instruments. Validity of the instruments requires
18
19 the absence of second-order serial correlation in the differences specification; overall validity
20
21 of instruments can be tested using a Sargan-type test. The Appendix shows more in detail the
22
23 assumptions underlying the system GMM estimation and its application to model (4).⁷
24
25
26

27 As far as *G*SIZE is concerned, the instruments used in the cross section (*DEP*, *URB*,
28
29 *POP*) exhibit enough time variation to be used in our panel; additionally, we use the same lag
30
31 structure as for the fiscal policy variable to improve the informational content of the
32
33 instruments. Table 4 summarizes the results of the least square dummy variable (LSDV) and
34
35 the GMM estimates for alternative GDP components.
36
37

38 < Table 4 here >
39
40

41 Again we find a significant destabilizing effect of fiscal policy on the volatility of GDP and
42
43 all of its components (per capita). Including country- and time-specific effects hardly affects
44
45 the values of the parameter estimates which are very close to the corresponding cross-section
46
47
48
49
50

51 ⁷ Another requirement for the application of the GMM system estimator is that the series are stationary. We
52
53 checked for stochastic trends using panel unit root tests, allowing for individual root processes: the null of a unit
54
55 root is rejected for both output volatility and our fiscal measures. Regarding the presence of deterministic trends,
56
57 it should be borne in mind that all models include time-specific effects; this is equivalent to transforming the
58
59 data into deviations from time means, which implicitly controls for the presence of a common trend.
60

1
2
3 estimates⁸. As expected, the estimates are more precise, resulting in an improved significance
4
5 level of the coefficients of our fiscal policy variable. As before, the LSDV estimates appear to
6
7 suffer from a downward bias; the GMM estimates are always larger.
8

9
10 The results cast only little doubt on the validity of the instruments; the tests for serial
11
12 correlation indicate significant (negative) first order serial correlation, but no second order
13
14 serial correlation (as it should be the case if the original residuals in (4) are serially
15
16 uncorrelated, which is required for the instruments to be valid). In two cases the Sargan test
17
18 (based on the one-step residuals) rejects the null of valid instruments; since the test is derived
19
20 under the maintained assumption of homoscedasticity, this could also be due to
21
22 heteroscedasticity. For two reasons this is likely to be the case here: first, the Sargan tests
23
24 based on the two-step estimates are all insignificant with p-values close to one. Second, it is
25
26 implausible that the instruments are invalid for private GDP, but not for the four GDP
27
28 components, which sum up to private GDP. Together with the cross-section results there
29
30 remains hardly a doubt that aggressive use of discretionary fiscal policy has a pervasively
31
32 destabilizing effect on output.
33
34
35
36
37

38 **IV. Fiscal policy and inflation volatility**

39
40 The amplification of business cycles is not the only destabilizing effect fiscal policy may
41
42 have; aggressive use of fiscal policy is also argued to increase uncertainty about future
43
44 inflation, for example, via its impact on aggregate demand, expectations about the
45
46 sustainability of fiscal policy, and the effect of taxes on marginal costs and consumption.
47
48 Rother (2004), who also provides a survey of the literature, finds evidence for a positive link
49
50 between discretionary fiscal policy (measured as year-on-year changes in the cyclically
51
52
53
54

55
56 ⁸ See the results for σ_i^{GC} in Table 2 and Table A2; this is also true for the effect on the volatility of GDP
57
58 components (not shown in the paper for σ_i^{GC}).
59
60

1
2
3 adjusted deficit) and inflation volatility, using a sample of 15 OECD countries over the
4
5 periods 1967 to 2001. This issue is of no less importance than the impact of fiscal policy on
6
7 output volatility; it was already Friedman (1977) to argue that it is not inflation per se but
8
9 inflation volatility that is harmful to economic growth. Empirical evidence supporting this
10
11 proposition is provided by Froyen and Waud (1987) and Judson and Orphanides (1999). We
12
13 will take up this issue here and test the impact of fiscal policy on inflation volatility as well.
14
15

16 In its basic setup, the subsequent analysis corresponds to that of section III. The
17
18 empirical model is similar to (3), now with the standard deviation of inflation (measured as
19
20 the growth rate of the GDP deflator⁹) as dependent variable and with a slightly different set of
21
22 control variables. Thus, we have
23
24

$$25 \ln \sigma_i^\pi = \alpha + \gamma \ln \sigma_i^{FP} + \delta \mathbf{W}_i + \varepsilon_i \quad (5)$$

26
27
28 In line with the analysis by Rother (2004), the matrix \mathbf{W} includes the following controls: the
29
30 level of inflation (π), which is widely recognized as important determinant of inflation
31
32 volatility; *G*SIZE and *T*RADE are included for the same reasons as above. Finally the (log of
33
34 the) volatility of the change in the output gap (σ_i^{GAP}), the volatility of the growth rate of the
35
36 nominal effective exchange rate (σ_i^{NEER}), and the volatility of adjusted money growth (σ_i^{GM})
37
38 may affect inflation volatility for obvious reasons and are thus controlled for in the regression.
39
40 A detailed description of the variables and data is given in the Appendix.
41
42
43
44

45 Again we estimate (5) as cross-section using annual data and as panel using quadrennial
46
47 time periods (based on quarterly data), which includes country- and time-specific fixed
48
49 effects. Endogeneity of the fiscal variable and government size may be an issue here for the
50
51 same reasons as above (reverse causality, measurement error); to address these concerns we
52
53 use the same set of instruments as above: in the cross-section estimation of (5), *MAJ*, *PRES*,
54
55
56
57

58
59 ⁹ As an alternative measure, we used the CPI deflator, and obtained qualitatively identical results.
60

1
2
3 *PCON*, and *NEL* are used as instruments for $\ln \sigma_i^{FP}$, and *DEP*, *URB* and (the log of) *POP* as
4
5 instruments for *GFSIZE*; in the panel estimation of (5), a GMM-system approach is employed
6
7 again, with the same lag structure as above (and *DEP*, *URB* and (the log of) *POP* are again
8
9 used as additional instruments for *GFSIZE*). Table 5 summarizes the cross-section and the
10
11 panel estimates of equation (5).
12
13

14
15 < Table 5 here >
16

17
18 Results are unambiguous, but different from that for output volatility: We find no evidence for
19
20 a direct link between discretionary fiscal policy and inflation volatility, no matter which
21
22 measure is used. It should be noted that the interpretation of the cross-section results is
23
24 severally aggravated due to the small number of degrees of freedom and collinearity
25
26 problems; this may also explain the wrong sign of the output gap variability in some of the
27
28 regressions. Hence, the cross-section results should not be overstressed.
29
30

31 In the panel estimation the fiscal policy variable turns out insignificant again.¹⁰ A
32
33 substantial part of the variation in inflation volatility is explained by the level of inflation, the
34
35 volatility of the output GAP, and the volatility of the nominal effective exchange rate; each of
36
37 these variables is significant and the coefficients show the expected positive sign. An
38
39 important point is that the volatility of the output gap can be replaced by the volatility of GDP
40
41 (or GDP per capita) growth, without altering the basic results (The only difference is that the
42
43 negative coefficient of the volatility of adjusted money growth becomes significant, too.). We
44
45 conclude that fiscal policy has no direct effect on inflation volatility, but it may increase
46
47 inflation volatility indirectly via its effect on output volatility (obtained in section III).¹¹ This
48
49 indirect effect is only of moderate size, however; using the effect of fiscal policy on output
50
51
52

53
54
55 ¹⁰ This holds true if the volatility of the output gap is omitted.

56
57 ¹¹ The similarity of the results when the volatility of the output gap is replaced by that of output growth (per
58
59 capita) is plausible; if the trend growth were constant the two variables should measure exactly the same thing.
60

1
2
3 volatility calculated in section III, the attainable reduction in inflation volatility implied by the
4
5 GMM estimates (using output volatility in (5) rather than the output gap volatility) amounts to
6
7 some 14 per cent on average.
8

9
10 These results are in strong contrast to that of Rother (2004). This is surprising, since the
11
12 two samples overlap to a considerable extent both with respect to the cross-country and time
13
14 dimension. Since the Rother (2004) study uses only one crude measure of fiscal policy, our
15
16 results, using a variety of measures, cast strong doubt on a direct link between inflation
17
18 volatility and fiscal policy. The insignificant results may also reflect country-specific
19
20 differences; it might be worth to pursue this question further and to investigate country-
21
22 specific effects of fiscal policy on inflation volatility in a time series framework.
23
24

25 26 27 **V. Fiscal rules and the room for discretionary fiscal policy**

28
29 Many OECD countries introduced fiscal rules over the last 15 years; the EU's Maastricht
30
31 criteria and the Stability and Growth Pact (SGP) are only the most prominent examples. Table
32
33 6 summarizes the fiscal rules introduced in selected OECD countries since 1990. A more
34
35 detailed overview is given by OECD (2002).
36
37

38
39 < Table 6 >
40

41
42 Two main arguments are usually put forward for the introduction of fiscal rules: to ensure
43
44 sustainability of fiscal policy, and to limit the room for erratic discretionary fiscal policy in
45
46 order to improve macroeconomic stability. It is widely recognized now that the Maastricht
47
48 criteria together with the SGP had a disciplinating effect on fiscal authorities, and that they
49
50 were a driving force of the fiscal consolidations in many EU countries in the 1990s. There is
51
52 less evidence on whether fiscal rules have actually supported macroeconomic stability. The
53
54 results in section II suggest that limiting the use of discretionary fiscal policy is a channel via
55
56 which fiscal rules could potentially reduce output volatility (and indirectly inflation volatility
57
58
59
60

1
2
3 as well). It is unclear, however, whether the fiscal rules introduced have actually achieved a
4
5 reduction in the use of discretionary policy. Fatas and Mihov (2003b), by casual inspection of
6
7 the development of the euro area's (average) fiscal stance (in terms of the year-on-year
8
9 change in the cyclically adjusted budget, and alternatively, using a measure similar to that in
10
11 section II) argue that there is some evidence in favour of this presumption.
12

13
14 The use of quarterly data allows us to pursue a more formal approach and to explicitly
15
16 test for a break in the volatility of discretionary fiscal policy. Table 7 gives an overview of the
17
18 aggressiveness of fiscal policy before and after the introduction of the fiscal rules shown in
19
20 Table 6. To avoid distortions from the rather erratic 1970s our samples start with year 1980.
21

22
23 < Table 7 >
24

25
26 It is remarkable that for all countries except Sweden and Switzerland the volatility of
27
28 discretionary policy has decreased. In judging whether the changes are also statistically
29
30 significant, it has to be borne in mind that our measures of fiscal shocks are residuals from a
31
32 regression model (i.e. we are actually testing for heteroscedasticity in the residuals of model
33
34 (1)). Since the residuals are not independent¹², a simple F-test using the ratio of the two
35
36 variances is not applicable. Therefore, we use a Breusch-Pagan Lagrange multiplier test (see
37
38 Greene, 2003, 223f.). Since the number of observations in our subsamples is fairly low, and
39
40 the test is known to be rather sensitive against the normality assumption we use the robust
41
42 variance estimate suggested by Basset and Koenker (1982). It turns out that of the 16 cases
43
44 considered, 11 changes turn out significant. Nine of the significant changes point to a
45
46 reduction in volatility; six of these nine countries are part of the euro area and underlie the
47
48 rules of the EU Stability and Growth Pact (SGP) including possible sanctions in the case of
49
50 non-compliance (which do not apply to the 'outs'). To reinforce the point, Figure 2 shows a
51
52
53
54

55
56 _____
57 ¹² Since $e = My = M\varepsilon$, where $M = I - X(X'X)^{-1}X'$, it follows that $\text{Var}(e) = \text{Var}(M\varepsilon) = \sigma^2MM' = \sigma^2M$, which is not
58
59 diagonal (even if $\text{Var}(\varepsilon) = \sigma^2I$).
60

1
2
3 scatter plot of the change in policy volatility against the change in volatility of output per
4
5 capita.
6

7
8 < Figure 2 here >
9

10
11 Some more discussion on the euro area countries seems warranted; we chose 1997 as
12
13 breakpoint, the year when the SGP was passed; basically the same results are obtained if we
14
15 use 1999 (SGP into force) and largely also if we use 1995 as breakpoint. However, if we
16
17 move back to 1992, the year when the Maastricht treaty was agreed upon, the observed
18
19 pattern of changes in Table 7 disappears. A possible interpretation is that fiscal rules take time
20
21 to gain acceptance and that it was the SGP, which ultimately strengthened the credibility and
22
23 commitment envisaged in Maastricht treaty. It is at least difficult to think of any other reason
24
25 that has affected almost all euro area countries alike. Ironically, a few years after the SGP
26
27 started to showed a recognizable effect on fiscal policies (at least according to Table 7), the
28
29 budget problems of several euro area countries (particularly France and Germany) and the
30
31 lack of enforcement of the SGP have lead to a reform proposal by the Commission with
32
33 extended escape clauses, such that the SGP is widely believed to have lost most of its
34
35 credibility and bit.
36
37

38
39 But also for five non-euro area countries (Australia, Canada, Norway, Japan, USA) we
40
41 observe a statistically significant reduction in volatility. This is remarkable, given the
42
43 different nature of the rules: in Australia, they imply little more than an obligation to declare
44
45 fiscal goals and to have fiscal policy reviewed by external auditors; in Canada's provinces,
46
47 possible sanctions range from a reduction in salaries up to forced elections.
48
49

50
51 Overall, our tentative evidence is suggestive: fiscal rules appear to have indeed
52
53 restricted the room for manoeuvre for discretionary fiscal policy. Our assessment is subject to
54
55 some qualifications: the number of observations is small and the trend may have reversed in
56
57 the late 1990s in some countries. It also provides no answer on why rules, so different in their
58
59
60

1
2
3 nature, had similar effects. Detailed case studies of single countries may be an interesting
4
5 extension in order to assess the exact way fiscal rules may have impacted upon fiscal
6
7 behaviour.
8
9

10 11 **VI. Conclusions**

12
13
14 This paper studies extensively the link between fiscal rules, the use of discretionary fiscal
15
16 policy and macroeconomic stability in terms of volatility of GDP per capita (and its
17
18 components) and volatility of inflation, using a sample of 20 OECD countries. We use both a
19
20 cross-section approach based on annual data and a panel approach based on quarterly data.
21
22

23
24 Concerns with respect to the proper measurement of discretionary fiscal policy are addressed
25
26 by using alternative variables (ranging from government consumption over the revenues side
27
28 to the government's net primary lending) and two alternative approaches to extract the
29
30 discretionary, i.e. the exogenous structural component of fiscal policy from the data. Concerns
31
32 with respect to (remaining) endogeneity of our fiscal policy variable as a result of possibly
33
34 reverse causality and measurement error are taken up as well: in the cross-section analysis we
35
36 use (mainly time invariant) data on institutions (such as electoral system and political
37
38 constraints) as instrumental variables; in the panel analysis we employ a system GMM
39
40 approach to check the sensitivity of the results with respect to assuming exogeneity of our
41
42 fiscal variable. We then provide some tentative analysis of whether the fiscal rules introduced
43
44 in several OECD countries since the early 1990s have altered the extent to which
45
46 governments use discretionary fiscal policy.
47
48

49
50 We identify three empirical regularities: i) There remains little doubt that aggressive use
51
52 of fiscal policy exerts a statistically significant and economically sizeable effect on volatility
53
54 of GDP. Since we find a destabilizing effect on all GDP components, the effect of fiscal
55
56 policy goes beyond amplifying business cycles by just adding noise to the output series:
57
58 Fiscal shocks are propagated through the whole economy and spill over to 'private' GDP
59
60

1
2
3 components as well. This enforces the results obtained by Fatas and Mihov (2003a) and
4
5 suggests that reduced use of fiscal policy over time is another source of the change in business
6
7 cycle volatility observed in many studies.
8

9
10 ii) In contrast to a recent study by Rother (2004), we find no evidence that discretionary
11
12 fiscal policy exerts a direct destabilizing effect on inflation. No matter which measure or
13
14 approach is used, the fiscal variable turns out insignificant. Since the volatility of the output
15
16 gap (or equivalently, the volatility of output) is found to be an important determinant of
17
18 inflation volatility, however, fiscal policy exerts an indirect destabilizing effect on inflation.
19

20
21 iii) Comparing the volatility of discretionary fiscal policy in OECD countries before and
22
23 after the introduction of fiscal rules, we find surprisingly consistent results: In most countries
24
25 the use of discretionary fiscal policy was reduced; in many cases this reduction is statistically
26
27 significant. This is surprising, since the rules considered are rather different in their nature and
28
29 with respect to the possibilities of legal enforcement. In-depth studies of single countries may
30
31 yield interesting answers on the question how fiscal rules have exactly altered the conduct of
32
33 fiscal policy.

Appendix

Data: Definition of variables, sources and samples

Unless stated otherwise, data were taken from the OECD Economic Outlook Database. Series for West Germany as of 1991 were partly chained using data of the reunified Germany. Quarterly data for population had to be interpolated. Variables on fiscal decentralization were kindly provided by Markus Eller. Cross-country dimension and time dimension: see Table A1.

DEP dependency ratio, i.e. ratio of people younger than 15 and older than 64 to working age population (people from 15 to 64) in per cent. Source: World Development Indicators.

EXP real primary expenditures in millions of Euros (base year 1995), general government total disbursements exc. gross interest payments, converted into real terms with GDP deflator .

FD^{EXP} share of sub-national government expenditures in general government expenditures net of intergovernmental transfers; Source: World Bank, IMF.

FD^{REV} share of sub-national government revenues in general government revenues; Source: World Bank, IMF.

GAP output gap in per cent of potential output, $GAP = 100 \times (GDP - GDP^*) / GDP^*$.

GC real general government consumption in millions of Euros (base year 1995).

GDP p.c. real GDP per capita in 1995\$ per person (base year 1995, 1995 PPPs of the OECD);

$$GDP\ p.c. = GDP^{**} / POP$$

GDP real GDP in millions of Euros (base year 1995).

- 1
2
3 *GDP** real potential output in millions of Euros (base year 1995).
4
5
6 *GDP*** real GDP in millions of 1995\$ (base year 1995, 1995 PPPs of the OECD).
7
8
9 *D* general government gross financial liabilities in per cent of GDP.
10
11
12 *GM* adjusted money growth, defined as money growth (based on M1) minus real GDP
13 growth. Source: data on M1 taken from IFS.
14
15
16
17
18 *GS* real general government spending in millions of Euros (base year 1995); $GS =$
19 $CG+IG$.
20
21
22
23 *GSIZE* government size in per cent of GDP, $GSIZE = 100 \times GS/GDP$.
24
25
26
27 *IG* real general government fixed capital formation in millions of Euros (base year
28 1995).
29
30
31
32 *MAJ* zero-one dummy for electoral system (1 for majoritarian, 0 for proportional).
33 Source: Person and Tabellini (2001).
34
35
36
37 *NEER* index of nominal effective exchange rate (1995=100).
38
39
40
41 *NEL* number of elections. Source: Database of Political Institutions.
42
43
44 *NL* real primary deficit (net lending) of general government in per cent of GDP;
45 $NL = (REC-EXP)/GDP$.
46
47
48
49 *NLA* *NL*, cyclically adjusted (by OECD) and expressed in per cent of potential output.
50
51
52
53 *OIL* oil price in US-\$ per barrel; Source: IFS.
54
55
56 *PCON* index of political constraints, based on Henisz (2000) and taken from the author's
57 Webpage.
58
59
60

- 1
2
3 *POP* population in million persons.
4
5
6 *PRES* zero-one dummy for regime (1 for presidential, 0 for parliamentary). Source: Person
7
8 and Tabellini (2001).
9
10
11 *REC* real primary receipts (base year 1995), general government total receipts exc. gross
12
13 interest receipts in millions of Euros, converted into real terms with GDP deflator.
14
15
16
17 *TRADE* imports plus exports of goods and services in per cent of GDP.
18
19
20 *URB* urbanization rate, i.e. urban population as share of total population in per cent.

22 Source: World Development Indicators.
23
24
25
26 π rate of inflation, measured as relative change in GDP deflator in per cent.
27
28
29

30 **GMM system estimation of model (4)**

31
32 The original specification of equation (4) in levels is given by

$$33 \ln \sigma_{i,t}^{\Delta \ln y} = \alpha_i + \gamma \ln \sigma_{i,t}^{FP} + \delta \mathbf{W}_{i,t} + \eta_t + \varepsilon_{i,t}. \quad (A1)$$

34
35 Each equation in levels is supplemented by an equation in first differences

$$36 \Delta \ln \sigma_{i,t}^{\Delta \ln y} = \gamma \Delta \ln \sigma_{i,t}^{FP} + \delta \Delta \mathbf{W}_{i,t} + \Delta \eta_t + \Delta \varepsilon_{i,t}. \quad (A2)$$

37
38
39 The cross-section dimension i runs from 1 to N , the time dimension t from 1 to T_i (unbalanced
40
41 panel). For the sake of brevity, we restrict our attention to the variable $\ln \sigma_{i,t}^{FP}$ here; for *GFSIZE*
42
43 (which is contained in \mathbf{W}), exactly the same lag structure is used (and *URB*, *DEP*, and *POP*
44
45 are used as additional instruments).
46
47
48
49
50
51
52
53

54
55 In equation (A2) $\ln \sigma_{i,t-2}^{FP}$ and all previous lags are used as instruments for $\Delta \ln \sigma_{i,t}^{FP}$
56
57 assuming that $E[\varepsilon_{i,t} \varepsilon_{i,s}] = 0$ for $i = 1, \dots, N$ and $s \neq t$ and exploiting the moment conditions that
58
59
60

1
2
3 $E[\ln \sigma_{i,t-s}^{FP} \varepsilon_{i,t}] = 0$ for $t = 3, \dots, 1999$ and $s \geq 2$. As a result of differencing and lagging (of the
4
5 instruments), only T_i-2 equations in first differences remain.
6

7
8 In (A1) lagged first differences ($\Delta \ln \sigma_{i,t-1}^{FP}$) are used as instruments¹³ for $\ln \sigma_{i,t}^{FP}$, based
9
10 on the assumption that $E[\alpha_i \Delta \ln \sigma_{i,2}^{FP}] = 0$ for $i = 1, \dots, N$, which (together with the standard
11
12 assumptions for (A2)) yields the additional moment conditions $E[\nu_{i,t} \Delta \ln \sigma_{i,t-1}^{FP}] = 0$ for
13
14 $i = 1, \dots, N$ and $t = 3, \dots, T_i$, where $\nu_{i,t} = \alpha_i + \varepsilon_{i,t}$.¹⁴ Using Monte Carlo studies, Blundell and
15
16 Bond (1998) demonstrate that the finite sample bias of the GMM estimator based on first
17
18 differences only can be reduced substantially with the system GMM estimator.
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44

45
46 ¹³ Note that there are no instruments for the first observation $\ln \sigma_{i,2}^{FP}$ available; as a result of differencing, T_i-1
47
48 equations remain.
49

50 ¹⁴ This requires the first moment of $\ln \sigma_{i,t}^{FP}$ to be stationary (which is fulfilled here).

| No. | 20 | 19 | 18 | 18 | 18 | 18 | 18 |

Notes: Starting year of adjusted samples (number of observations); all series go up to 2002 (2002q4).

In the estimations of the models for inflation volatility, the annual samples are almost the same; only MEX had to be excluded due to missing data on the output GAP. In the quarterly samples, BEL, CHE, ESP, MEX, and KOR had to be excluded, again due to missing output GAP data. (Overall, the samples also reflect limited data availability of other variables used in the estimation such as institutional variables; JPN, for example, could be included in the quarterly analysis where no institutional variables are required).

| observations | 18 | 18 | 18 | 18 | 18 | 18 |

Notes: Dependent variable is (the natural log) of the standard deviation of GDP per capita growth ($\sigma_i^{\Delta \ln y}$). All regressions contain a constant. σ_i^{FP} is the standard deviation of the respective measure of fiscal shocks. The p-values in parentheses are based on heteroscedasticity-robust standard errors. OID reports the p-value of the heteroscedasticity-robust test of overidentifying restrictions in the instrumental variable regression (see Wooldridge, 1998).

Table 3.

Fiscal policy (measured as σ_i^{NL}) and volatility of GDP components (per capita)

| | consumption | | investment | | exports | | imports | |

| observations | 142 | 298 | 148 | 318 | 148 | 318 |

Notes: p-values in parenthesis are based on robust standard errors. Cross-sections dimension $i = 18$ countries; time dimension T_1 is country-specific, ranging from 4 to 11 (depending on data availability). All models include individual- and time-specific fixed effects. GMM ... one step GMM-system estimates (Blundell and Bond, 1998) using robust standard errors. m_1 (m_2) are the p-values of first (second) order serial correlation test. Sargan test (which assumes homoscedasticity) is the one-step version (p-values of Sargan test based on two-step residuals are close to one). To ensure comparability both LSDV and GMM estimates cover the same time period.

Notes: Cross-section estimates: see also Table 2. Panel estimates: Cross-section dimension $i = 13$ countries; time dimension T_i is country-specific, ranging from 4 to 11. ¹⁾ is value of the one-step variant of Sargan test (again, The p-value of the two-step variant is close to one); p-values of tests for first order and second order serial correlation tests are 0.009 and 0.365, respectively.

Table 6.
Fiscal rules introduced in OECD countries since 1990

Australia: *Charter for Budget Honesty, 1998*

Rules: No legislated numerical rules; government is required to specify targets (no constraints on their nature).

Enforcement: Annual fiscal strategy statement; assessment by external auditors. No sanctions.

Austria: *Domestic Stability Pact, 2000*

Rule: Negotiated floors on budget balance for each government level; floors apply on average, over several years.

Enforcement: Possible fines (up to a ceiling), subject to unanimous decision from all interested parties.

Belgium: *Intergovernmental treaties, 1996 to 2002*

Rule: permissible deficits for federal government, Social Security, regions and local governments.

Enforcement: Permissible deficits based on recommendations of the High Council of Finance (a wise men committee), which are published in annual reports.

Canada: *Federal Spending Control Act, 1991-1996*

Rules: Limits on programme spending (except self-financing programmes); overspending in one year permitted if offset in following two years.

Enforcement: No explicit sanctions; assessment of compliance with the Act by Auditor General.

Debt Repayment Plan 1998

Rules/Enforcement: Federal government: no legislated rules, but “balanced budget or better” policy; provinces: balanced budget legislation (with sanctions including salary cuts for cabinet members or forced elections.)

Euro area/EU countries: *Maastricht Treaty, 1992; Stability and Growth Pact, 1997*

Rules: 3 per cent of GDP ceiling on general government net borrowing; 60 per cent of gross government debt-to-GDP ratio norm; “Close to balance or surplus” target.

Enforcement: Annual stability (euro area “ins”) or convergence (“outs”) programme, which is subject to an opinion from the Council. Excessive deficit procedure; from peer pressures, based on policy recommendations based on the Commission’s assessment to non-remunerated deposits.

Japan: *Fiscal Structural Reform Act, 1997/1998*

Rules: Reduction of fiscal deficits to 3 per cent of GDP by 2003; termination of issuance of special deficit-financing bonds by 2003; numerical reduction targets for major expenditure areas over next three years.

Enforcement: No explicit sanctions.

Norway: *Fiscal Stability Guidelines, 2001*

Rules: Structural non-oil central-government budget deficit should equal 4 per cent of the Government Petroleum Fund over the cycle; discretionary easing or tightening during the cycle is allowed.

Enforcement: Reports of the structural fiscal balances including and excluding oil revenues, complemented with annual update of long-term projections; no sanctions.

Sweden: *Fiscal budget Act, 1996*

Rules: Nominal expenditure limits for subsequent three years on 27 expenditure areas (including social security); maintain a general government surplus of 2 per cent of GDP on average over the business cycle.

Enforcement: No explicit sanctions.

Switzerland: *Budget Objective 2001, 1998*

Rule: federal deficit capped at 2 per cent of revenues or 0.25 per cent of GDP by 2001; Debt Containment Rule

Enforcement: Expenditure excess to be financed by tax increase.

UK: *Code for Fiscal Stability, 1997*

Rules: Golden rule (over the cycle the government will borrow only to invest); sustainable investment rule (net debt as a proportion of GDP must be held stable over the cycle at a prudent level; defined as 40 per cent).

Enforcement: Annual reporting cycle (Pre-Budget Report, Economic and Fiscal Strategy Report, Debt Management Report); no explicit sanctions.

USA: *Budget Enforcement Act, 1990 to 2002*

Rules: Medium-term nominal caps for discretionary spending; legislated changes to revenues or mandatory spending programmes should be budget neutral over a five-year horizon.

Enforcement: Sequestration procedures (cuts across-the-board).

Source: OECD (2002).
