ABSTRACT

This study utilizes panel data as a means of examining the determinants of foreign direct investment (FDI) in Spain. Data that takes in the period 1993 to 2002 is used in order to estimate the determinants of FDI, at the sectoral level, by differentiating the manufacturing sectors, and at the regional level. The analysis investigates the sectoral, regional and macroeconomic variables that have successfully attracted FDI inflows from those that have not. Empirical results suggest that the differential between labour productivity and the cost of labour has been an important determinant of FDI in Spain during the period 1993-2002. Factors related to demand, the evolution of human capital, the export potential of the sectors, and certain macroeconomic determinants that measure the differential between Spain and the European Union average, also play a very important role in attracting flows of FDI. Certain policy issues that are relevant to the results are also discussed.

Running Title: Determinants of Foreign Direct Investment in Spain

Keywords: foreign direct investment (FDI), panel data, Spanish sectors and regions

1. INTRODUCTION

Foreign Direct Investment (FDI) has been instrumental in shaping the dynamic of the globalization process within different economies and the Spanish economy has been no exception. FDI, besides having important implications in terms of a country's balance of payments, also affects the productive structure of the country receiving the investment, its business organization, potential technological change and innovation and the geographical distribution of production and employment. It would seem important from an empirical perspective therefore, to be able to establish and analyze those factors that have played a key role in determining FDI in Spain.

A review of the literature that focuses on the determinants of Spanish FDI, reveals that most empirical research have focused on the study of macroeconomic variables and have used aggregate data for the whole of the Spanish economy (Varela and Rodríguez de Pablo, 1974; Donges, 1976; Felipe and Fernández, 1991; Bajo, 1991a; Bajo and Sosvilla, 1991; Bajo and Sosvilla, 1992; Muñoz, 1999). From the early 1990's onwards however, this type of study has also been carried out on a regional level (Egea and López, 1991b; Díaz, 2001).

This paper investigates the determinants of FDI in Spain by simultaneously examining macroeconomic, sectoral and regional factors. The present study also incorporates a wider range of factors than those that have previously attempted to analyze FDI in Spain. The paper is organized as follows. Section 2 both reviews and explains some of the methodological issues related to the modelling of FDI determinants. Section 3 contains the empirical analysis. The final section provides some conclusions and policy recommendations.

2. METHODOLOGY

The methodology most frequently adopted when analyzing the factors that determine foreign investment is conditioned by the fact that the agents of this investment are firms. The works of Barrell and Pain (1991), Stevens and Lipsey (1992) or Bajo and Sosvilla (1992, 1994) provide sturdy foundations upon which to base a theoretical model. The above studies suggests the following relationship between FDI (at any given moment in time) and its determinants:

$$IED_t = h(D_t, C_t, B_t, K_{t-i}, E_t) \quad [1]$$

where D represents the size of the domestic market (the aggregate demand), C represents the relative unit costs (of the host country compared to the country of origin), B represents the potential trade barriers, K_{t-i} represents the volume of foreign capital at the start of the period analyzed and E^1 represents a group of factors that are external to the firm but which are capable of significantly influencing its levels of production

The empirical models that are concerned with the determinants of foreign investment usually consist of a generalized version of the theoretical model [1]². The specification of the empirical model normally involves using a multiple regression model, one which is usually log-linear (Bajo and Sosvilla, 1992; Muñoz, 1999). Therefore, equation [1] can be written as:

$$\ln IED_t = \beta_0 + \beta_1 \ln D_t + \beta_2 \ln C_t + \beta_3 \ln B_t + \beta_4 \ln K_{t-i} + \beta_5 \ln E_t + \varepsilon_t \quad [2]$$

where Ln represent natural logarithms.

There is a distinct lack of consensus, in the vast majority of empirical studies, as to the relative importance and the direction of the impact of the potential determinants of FDI. This suggests that the exact relationship between FDI and its determinants

¹ Porter (1986) and Esteban and Vives (1994) underline the fact that neither production nor productivity depend solely upon the level of physical capital and work but also upon other variables, factors that are external to the firms, such as the level of infrastructure, human capital, and technology.

²This generalization involves carrying out an extrapolation from the micro (or firm-level) to the macro (or country-level) and includes a number of determining factors which constitute a series of economic variables that might influence firms' costs and incomes and, in consequence, the decision to invest in the foreign country.

1
2
3 is essentially empirical. The aggregate demand or the size of the market of the
4 country that receives the direct investment should have a positive influence on FDI
5 (Billington, 1999; Chandprapalert, 2000; Love and Lage-Hidalgo, 2000;
6 Chakraborty and Basu, 2002; Janicki and Wunnava, 2004). Although there is no
7 complete consensus with respect to the empirical results obtained for relative unit
8 costs, most of these results indicate that they have a negative influence on FDI
9 (Chakrabarti, 2001). The effects of either openness or trade barriers on FDI have
10 also been widely debated. The ease of entry to economic markets may be a factor
11 that plays a role in the attraction of FDI (Root and Ahned, 1978); hence, it is to be
12 expected that, in general, barriers to trade act as a negative stimulus to FDI
13 (Mundell, 1957), although there are empirical studies that would seem to
14 contradict this point of view): while Culem (1988) reported a significantly negative
15 correlation between trade barriers and FDI, Lunn (1980) observed a positive
16 relationship, and Blonigen and Feenstra (1996) found that trade barriers play an
17 insignificant role in attracting FDI. Past decisions with respect to direct investment
18 may also affect future flows of FDI, in this case positively, since they establish
19 patterns of behaviour with respect to investment preferences. Finally, it is not
20 known, a priori, what effects the group of factors that are external to the firms
21 themselves will have; this will depend on the each individual factor. Factors such
22 as infrastructure, technological and human capital should have a significantly
23 positive effect on FDI.

3. EMPIRICAL ANALYSIS

Data and variables

51
52
53
54 The study of the determinants of FDI in Spain may adopt at least two distinct
55 approaches: the first of these involves considering the total aggregate investment
56 for the whole of Spain and the second uses different levels of investment in order
57 to study a regional or sectoral breakdown of FDI. The second approach also allows
58
59
60

1
2
3 the study to take advantage of the positive econometric effects that are derived
4 from the use of panel data techniques³. In order to maximize these advantages, the
5 determinants of foreign investment in Spain are analyzed by looking at a
6 breakdown of the 28 sectors of the Spanish economy (set out according to the
7 National Classification of Economic Activities, 1993). The 13 main manufacturing
8 sectors are then analyzed and a third application is also carried out for the 17
9 Spanish Regions. The temporal period covered in the study spans the years 1993-
10 2002.

11
12 The dependent variable used was gross effective investment which, in addition to
13 accurately reflecting the flows of FDI, facilitates the sectoral and regional analysis
14 of said investment. Hence, this empirical work uses the homogeneous series of
15 Gross Effective Foreign Investment provided by Spanish Ministry of Economy
16 (SME) since this is believed to be the best indicator of FDI.

17
18 A priori, there would seem to be a wide and varied array of potential factors, both
19 intrinsic and extrinsic to the firms that might in some way affect the foreign firms'
20 decisions to invest in any given country (see Muñoz, 1999). On looking at the FDI
21 literature cited above and by taking equation [2], it may be deduced that the
22 empirical model should include at least three types of FDI determinants: factors
23 linked to the demand or the size of the market (D), factors that ultimately affect the
24 firms' costs or profits –such as the group of factors C, B, E- and, to some extent,
25 the previous decisions taken with respect to FDI (K_{t-i}). Table 1 therefore, provides
26 a regional and a sectoral breakdown of the determinants of Spanish FDI.

Specification of the models and results

The empirical analysis of the determinants of FDI, which utilizes a breakdown of the flows of investment received, in terms of productive sectors and autonomous regions, is estimated using panel data techniques. Therefore, if there is a panel of N sectors or regions, for T periods of time, the model [2], which does not consider specific temporal effects, may be expressed as follows:

$$\text{LnFDI}_{it} = \alpha_{it} + \beta_i' \text{LnX}_{it} + \varepsilon_{it}; \quad i=1, \dots, N; t=1, \dots, T \quad [3]$$

where X_{it} and β_i are k -vectors of independent variables (determinants) and parameters respectively; α_{it} is the component which includes the specific characteristics (individual effects), and ε_{it} is the disturbance. The appropriate estimation method and the estimators' properties will depend on the characteristics of α_{it} and ε_{it} (and on the relation between them), as well as on the relation between the independent variables and the disturbance.

This work uses a panel of 252 observations for the temporal period of 1993-2002⁴ when all of the 28 selected productive sectors are available. 117 observations are available when the 13 manufacturing sectors are analyzed and 153 for the 17 regions. The estimations are carried out using the Econometric Views program 5.0.

The first part of the study evaluates three alternative forms of modelling (3). The proposals for modelling using fixed or random effects⁵ are not capable of adequately capturing heterogeneous or temporal performance or the performance

⁴ In this paper, the properties of the time series that were used were not studied because the number of annual observations was relatively small. As Shiller-Perron (1985) and Davison-Mackinnon (1993) point out, the power of the unit root test basically depends upon the chronological span of the data. In order to guarantee that the resultant regressions are not spurious, the relationships established by existing economic theory and other empirical analyses within the same field are taken into consideration.

⁵ The informatics system Econometric Views 5.0 has also been used in an attempt to include additional specific temporal effects. This option does not improve the results, rather, on combining the two types of effects (group and temporal), given the characteristics of the sample, tends to provoke situations in which there is perfect multicollinearity.

of different economic sectors or regions. The inclusion of a dummy variable ($DU_{it} = \alpha_{it}$) in order to capture the heterogeneity across economic units and over time has, in general, functioned satisfactorily. In the case of the sectoral analysis, breaking the sample down into 28 sectors of activity for the Spanish economy, the model that has achieved the best results is as follows:

$$\begin{aligned} \ln SECFDI_{it} = & \beta_0 DU_{it} + \beta_1 \ln(SECPLP_{it} - SECCOST_{it}) + \\ & + \beta_2 \ln SECFDI_{it-1} + \beta_3 FISC_t + \beta_4 \ln DM_{it} + \varepsilon_{it} \end{aligned} \quad [4]$$

where SECFDI represents the FDI for each sector. Given the existence⁶ of heteroskedasticity and the characteristics of the sample in which $T < N$, the most generic of the methods, SUR, cannot be applied. Hence the model [4] is estimated using the GLS (Cross Section Weights) method. The results of the estimation of this model are given in table 2.

The findings suggest that the model is robust. The adjusted- R^2 indicated good explanatory power. The reported F-statistic is substantial enough to conclude that there is joint significance of the chosen independent variables. The results indicate that the level of foreign direct investment according to sectors (SECFDI) depends on; the particularities of each sector (DU), the difference between the productivity of each employee and the cost of each employee ($SECPLP - SECCOST$)⁷, on past decisions ($SECFDI(-1)$) –those sectors that proved to have the most attractive power in the past also tend to maintain this power in the present -, the fiscal pressure in Spain (FISC) and the capacity that the sectors have in order to keep their domestic markets supplied (DM). As one might expect, all of these variables, with the exception of FISC, take a positive sign. The first four variables are significant at the conventional level of 5%. The DM variable is significant at 19%.

⁶ The Bartlett, Levene and Brown-Forsythe tests indicated the presence of heteroskedasticity.

⁷ The result of the individual inclusion of SECPLP and SECCOST in the model was not significant.

The 28 sectors analyzed are very heterogeneous and take in activities that vary substantially, both in terms of quantity and quality. Therefore, a specific analysis is carried out which looks at the 13 manufacturing sectors, i.e. those sectors that have most in common and those that focus on those processes of industrial transformation that are generally intensive. For the manufacturing sectors the following model provides the best results:

$$\begin{aligned} \ln SECFDI_{it} = & \beta_0 DU_{it} + \beta_1 \ln(SECPLP_{it} - SECCOST_{it}) + \beta_2 \ln SECFDI_{it-1} + \\ & + \beta_3 FISC_t + \beta_4 \ln DM_{it} + \beta_5 \ln SPCPI_t + \beta_6 \ln SECEXP_{it} + \varepsilon_{it} \end{aligned} \quad [5]$$

The model [5] is also estimated using the GLS (Cross Section Weights) method and the results are given in table 2. On utilizing the data relevant to the industrial branches alone, the significance of the variables included in model [4] is, once again, thrown into sharp relief. The one exception is the FISC variable which stops being statistically significant in explaining the behaviour of SECFDI⁸. Within the same context however, the analysis reveals that the SPCPI variable (prices in Spain compared to the EU average) is highly significant (and logically takes a negative sign), as is the SECEXP variable, which reflects the level of exports generated by the industrial sub-sectors and, to a certain extent, measures how competitive they are.

The capacity of a country to attract FDI may be measured in a disaggregate way by measuring the investment in its economic sectors or by considering the geographical location of the country within which this investment is taking place. In the case of the latter, the methodology involves trying to determine those factors that exist in a given zone that convince foreign firms to set up there. It is within this

⁸ To a certain extent, this indicates that, when foreign investment by companies holding foreign stocks is not included, as is the case of the manufacturing sectors, this variable ceases to be significant. This is because the main factor underlying the rise of this type of investment, which has an important relative weight as a proportion of total foreign investment, has been the fiscal incentives that Spain has offered with respect to the incomes obtained through foreign business investments (Tax Law of Companies, 43/1995).

line, therefore, that a model is offered which is similar to that provided in equations [4] and [5], but one which has been adapted for the Spanish scenario in which there are 17 quasi-autonomous regions:

$$\begin{aligned} \ln RFDI_{it} = & \beta_0 DU_{it} + \beta_1 \ln(RPLP_{it} - RCOST_{it}) + \beta_2 \ln RFDI_{it-1} + \beta_3 FISC_t + \\ & + \beta_4 \ln RGDP_{it} + \beta_5 \ln SPCPI_t + \beta_6 \ln RHK_{it} + \beta_7 DUM_t + \varepsilon_{it} \end{aligned} \quad [6]$$

where RFDI represents regional FDI. Model [6] is also estimated using the GLS (Cross Section Weights) method and the results are given in table 2. The results of the model [6] vindicate those obtained in former studies in the sense that the level of foreign direct investment according to region (RFDI) depends on the particularities of each region (DU), the difference between the value of the productivity per employee and the cost of each employee (RPLP-RCOST), on past decisions (the regions with the greatest power to attract FDI in the past continue to exert this power in the present) and demand factors, represented by the RGDP of each region. Of the two national Spanish variables, FISC and SPCPI, it is the SPCPI variable that reveals itself as being the most statistically important in explaining investment. The model [6] provides information which is not contained in [4] and [5] since the results indicate that regional human capital has a positive effect on attracting investment, an effect that is statistically significant at the 12% level as opposed to 5%. This is probably due to the fact that a part of its effect has already been captured by the partial labour productivity variable. On a regional level, Madrid must be modelled slightly differently, since it receives a particularly high relative proportion of investment. This is achieved by introducing a dummy variable for the region (DUM). The variable is significant at the 5% level and confirms the importance of Madrid as a national service centre.

INSERT TABLE 2 ABOUT HERE

1
2
3 If the endogeneity of the lagged dependent variable (FDI(-1)) is taken into account,
4
5 then the GLS (Cross Section Weights) method becomes inappropriate and an
6
7 instrumental variables method must be used. Potential methods include; the Two-
8
9 Stage Least Squares (2SLS), the Weighted Two-Stage Least Squares (W2SLS)
10
11 and the Three-Stage Least Squares (3SLS) methods. Given that this study uses
12
13 panel data, the W2SLS is used. The W2SLS is an appropriate technique when
14
15 some of the right-hand side variables are correlated with the disturbance term and
16
17 the model is heteroskedastic. The estimation of the models [4], [5] and [6] by
18
19 means of the W2SLS method is given in table 2, in which the variable FDI (-2) is
20
21 used as an instrument of FDI (-1).

INSERT TABLE 3 ABOUT HERE

The results presented in Table 3 vary slightly with respect to the earlier estimates presented in Table 2. One of the only really substantial differences is the improvement in the statistical significance of the human capital (HK) and relative fiscal pressure (FISC) variables, when the estimation is carried out by means of the W2SLS method in model [6].

4. CONCLUSIONS AND POLICY IMPLICATIONS

The vast majority of empirical studies analyzing the determinants of foreign investment in Spain have tended to focus upon macroeconomic factors and to a lesser extent on regional factors. This study looks jointly at macroeconomic, regional and sectoral factors.

The demand factors (DM and RGDP) have, in general, been statistically significant. This result is in line with those obtained by Egea and López (1991b), Bajo and Sosvilla (1992), Muñoz (1999) and Díaz (2001).

It should be underlined that, in the three models estimated in this study, the variable that takes in the difference between the productivity of labour and its cost

1
2
3 plays a key role in explaining the behaviour of FDI. This result both clarifies and,
4
5 reaffirms the results obtained in similar studies, in the sense that it quite clearly
6
7 shows that firms are motivated, not solely by the evolution of labour costs, but by
8
9 the relative difference between labour productivity and labour costs.
10

11
12 Human capital, which is a fundamental element of increased per-worker labour
13
14 productivity, when considered individually, is also a significant determinant of
15
16 foreign investment in the different regions.
17

18
19 In addition to productivity, a further indicator of competitiveness is the export
20
21 potential of the manufacturing sectors, which clearly reveals itself to positively
22
23 influence the entry of flows of foreign investment.
24

25
26 Of all of the macroeconomic factors utilized that measure the situation of Spain
27
28 with respect to the EU average (SPGDP, FISC, SPLTIR, SPCPI and SPIPI), the
29
30 two which, in general, have been statistically significant and take a negative sign in
31
32 the definitive models estimated by W2SLS were, fiscal pressure (FISC) and the
33
34 inflation differential (SPCPI).
35

36
37 Fairly predictably, the sectoral or regional determinants have performed better than
38
39 those that work on the national Spanish level (the specific factors have been shown
40
41 to be relatively more important than macroeconomic factors). This result is in line
42
43 with those obtained by Giuliatti, Mccorrison and Osborne (2004).
44
45

46
47 In view of the results, it would seem evident that economic policy in Spain
48
49 orientated towards attracting foreign direct investment, besides taking into account
50
51 the traditional factors of demand and costs should focus on boosting all of those
52
53 variables that favour the growth of labour productivity as is the case of investment
54
55 in education, research, innovation and technology.

TABLES

Table 1. The possible determinants of FDI

Variable	Description	Unit/Source
Factors of demand (Market size)		
SPGDP	Real Gross Domestic Product (GDP) in Spain	Thousand of euros /Spanish Statistical Institute (SSI)
SPEGDP	GDP in Spain compared to the EU average	Percentage/ EUROSTAT
RGDP	Real GDP of the Spanish regions	Thousands euros /SSI
DM	The proportion of sectoral production that is destined for the domestic market	Percentage/SSI
Factors of cost (profit)		
SPCOST	Mean cost per employee on average throughout Spain	Euros/SSI
RCOST	Mean cost per employee on average in each region	Euros/SSI
SECCOST	Mean cost per employee on average according to sector	Euros/SSI
SPPLP	Partial Labour Productivity on average in Spain	Euros/SSI
RPLP	Partial Labour Productivity, on average, according to region	Euros/SSI
SECPLP	Partial Labour Productivity according to sector	Euros/SSI
SUBS	Production subventions, made available by the Spanish Public Administration	Millions euros /SSI
FISC	Fiscal pressure (Direct and indirect taxes/GDP) in Spain compared to the EU average	Percentage/ OECD
SPLTIR	Long term interest rate in Spain compared to the EU average	Percentages/ EUROSTAT
SPCPI	Consumer price index in Spain compared to the EU average	Percentages/Spanish Ministry of Science and Technology (SMCT)
SPIPI	Index of industrial prices in Spain compared to the EU average	Percentages/ SMCT
RHK	Human capital according to region (percentage of employees with upper-secondary education level or over)	Percentage/SSI
SECHK	Human capital according to sector (percentage of employees with upper-secondary education level or over)	Percentage/SSI
SPPK	Public capital in Spain (as a proxy of the level of infrastructures)	Millions euros/SSI
TEC	Ratio of income, as measured on the Spanish technological balance of payments, to GDP (as a proxy of technological capital)	Percentage/SSI
Previous FDI decisions		

RFDI _{t-1}	The one-period lagged dependent variable according to region (as proxy of the volume of FDI at beginning of period)	Millions euros/ SME
SFDI _{t-1}	The one-period lagged dependent variable according to sector (as proxy of the volume of FDI at beginning of period)	Millions euros/ SME
Other location factors		
SECEXP	Exports by sector (as competitiveness indicator)	Millions euros/ SME
RPS	Productive structure by region, measured as a ratio between industrial Gross Value Added (GVA) and the total GVA of a region	Percentage/SSI

Table 2. Estimates of the models 6, 7 and 8. Method: GLS (Cross Section Weights)

Dependent Variable: Ln(?FDI)			
Independent Variable	Model [6] (Total sectors)	Model [7] (Manufacturing sectors)	Model [8] (Regions)
DU	1.094439 (10.59514)*	1.111707 (10.56652)*	1.122849 (7.330527)*
Ln(?PLP-?COST)	0.105245 (2.107667)*	1.311781 (9.171453)*	0.543657 (2.216901)*
Ln(?FDI(-1))	0.844293 (32.46423)*	0.327381 (5.030839)*	0.654079 (10.17201)*
Ln(FISC)	-2.043291 (-2.053786)*	-1.096478 (-0.372633)	-3.481905 (-0.892265)
Ln(DM)	0.941128 (1.339398)	4.723175 (2.960093)*	
Ln(SPCPI)		-1.559847 (-7.248110)*	-3.992940 (-3.845437)*
Ln(SECEXP)		0.823760 (6.4821671)*	
Ln(RGDP)			0.564193 (5.290689)*
Ln(RHK)			1.168325 (1.575153)
DUM			0.467840 (1.987841)*
Nº. of obser.	252	117	153
Adjusted R²	0.97	0.98	0.98
D-W	2.262	1.945	2.072
F-statistic	1900.7	914.1	869.1
Prob.(F-stat.)	0.00	0.00	0.00

Notes: 1. (?) Is substituted for (SEC) or (R) depending on whether the analysis refers to the sector or the region

2. t-ratio appear in parenthesis

3. (*) Indicate significance at the 5% level

Tabla 3. Estimates of the models 6, 7 and 8. Method: W2SLS

Dependent Variable: Ln(?FDI)			
Independent Variable	Model [6] (Total sectors)	Model [7] (Manufacturing sectors)	Model [8] (Regions)
DU	1.157284 (10.11943)*	1.259680 (9.895546)*	1.079991 (8.204694)*
Ln(?PLP-?COST)	0.104908 (1.983177)*	1.308470 (8.805573)*	0.542123 (2.256655)*
Ln(?FDI(-1))	0.838355 (30.16488)*	0.353388 (5.187197)*	0.679374 (10.78925)*
Ln(FISC)	-2.170680 (-2.10291)*	-1.892702 (-0.641471)	-8.931114 (-2.469780)*
Ln(DM)	0.900402 (1.210291)	4.977487 (3.086278)*	
Ln(SPCPI)		-1.664194 (-6.885075)*	-4.109263 (-4.496141)*
Ln(SECEXP)		0.851385 (6.235611)*	
Ln(RGDP)			0.542434 (5.420707)*
