## Abstract

Isocitrate dehydrogenase 1 R132H (*IDH1*<sup>R132H</sup>) mutation is a frequent alteration and a major prognostic marker in gliomas. However, direct sequencing of highly contaminated tumor samples may fail to detect this mutation. Our objective was to evaluate the sensitivity of a newly described amplification method, coamplification at lower temperature-PCR (COLD PCR), combined with high resolution melting (HRM) for the detection of *IDH1*<sup>R132H</sup> mutation. To this end, we used serial dilutions of mutant DNA with wild type DNA. PCR-HRM assay detects *IDH1*<sup>R132H</sup> mutation at an abundance of 25%, similar to the detection limit of direct Sanger sequencing. Introducing a run of COLD PCR allows the detection of 2% mutant DNA. Using two consecutive runs of COLD PCR, we detected 0.25% mutant DNA in a background of wild type DNA, that mimicks a tumor sample highly contaminated by normal DNA. We then analyzed ten biopsies of tumor edges, considered free of tumor cells by histological analysis, and showed that immunohistochemistry of *IDH1*<sup>R132H</sup> was positive in 3 cases (30%), whereas double COLD PCR HRM was positive in the ten cases studied (100%). In summary, COLD PCR HRM analysis is 100-fold more sensitive than Sanger sequencing, rendering this rapid and powerful strategy particularly useful for samples highly contaminated with normal tissue.

**Keywords:** *IDH1*<sup>R132H</sup> mutation, COLD PCR, High Resolution Melting, glioma

## Introduction

In recent years, recurrent mutations of the gene encoding isocitrate dehydrogenase 1 (*IDH1*; MIM# 147700) have been described at a high frequency in gliomas [Balss, et al., 2008; Bleeker, et al., 2009; Hartmann, et al., 2009; Ichimura, et al., 2009; Parsons, et al., 2008; Sanson, et al., 2009; Yan, et al., 2009]. Mutations in the *IDH1* gene always affect the codon 132, which in more than 90% of cases result in a substitution of arginine by a histidine residue, *IDH1*<sup>R132H</sup> [Ichimura, et al., 2009; Sanson, et al., 2009; Yan, et al., 2009]. Since it is almost exclusively found in gliomas, *IDH1* mutation has a strong diagnostic value [Yan, et al., 2009]. *IDH1* mutation is also a powerful independent prognostic factor in gliomas [Dubink, et al., 2009; Nobusawa, et al., 2009; Sanson, et al., 2009]: patients with an *IDH1*<sup>R132H</sup> mutated tumor having a longer survival when compared with those non mutated for the same grade. Given its diagnostic and prognostic potential, the determination of *IDH1* status in glioma samples is gaining increasing attention in clinical practice.

Conventional PCR followed by Sanger sequencing is currently the gold standard in identifying *IDH1* mutations in tumor DNA. Typically, clinical tumor samples are contaminated by normal tissue, thereby diluting the total amount of genetic that is present, and techniques are often required to identify low level alterations within an excess of wild-type DNA. This is particularly true for gliomas which are highly infiltrating tumors [Furnari, et al., 2007]. Conventional PCR enables mutation detection from a very small amount of sample but does not selectively amplify the mutant sequences. Therefore, unless the mutation exceeds a 20-25% abundance relative to wild-type alleles, conventional PCR followed by downstream methods such as Sanger sequencing will fail to detect mutations in clinical samples [Li, et al., 2009; Zuo, et al., 2009]. Enrichment methods are thus necessary to increase the mutant DNA /wild type DNA *ratio*. Tumor-cell enrichment methods, such as cell

1  
2  
3 sorting or microdissection, are expensive and time-consuming [Zuo, et al., 2009], and  
4  
5 therefore inadequate for clinical routine use.  
6  
7

8  
9 Recently, co-amplification at lower denaturation temperature PCR (COLD PCR) has  
10  
11 been described as a powerful method to identify low-level mutations in the *TP53* gene [Li, et  
12  
13 al., 2008; Milbury, et al., 2009]. This approach uses a critical temperature ( $T_c$ ) during the  
14  
15 PCR process in order to enrich mutations at any position of the amplified sequence. Indeed, a  
16  
17 single nucleotide mismatch anywhere along a double-stranded DNA sequence generates a  
18  
19 small change in the melting temperature for that sequence, with mutated sequences melting at  
20  
21 a lower temperature than wild-type sequences [Li, et al., 2008]. During COLD PCR, the  
22  
23 denaturation temperature is set to  $T_c$ , thereby mutation-containing sequences are  
24  
25 preferentially denatured and available for primers binding and subsequent amplification. High  
26  
27 Resolution DNA Melting (HRM) analysis is a relatively new and rapid method for detecting  
28  
29 DNA sequence variants following an initial amplification [Erali, et al., 2008; Vossen, et al.,  
30  
31 2009; Wittwer, 2009]. Gene scanning by HRM depends on the recognition of changes in the  
32  
33 shape of the amplicon melting curve that result from heterozygous sequence alterations [Erali,  
34  
35 et al., 2008]. At the end of PCR amplification, samples are heated to 95°C to ensure a  
36  
37 complete denaturation. Next, the temperature is reduced to allow cross-hybridization between  
38  
39 wild-type and mutant sequences, leading to the formation of mismatched heteroduplexes,  
40  
41 which melt at a lower temperature than wild-type and mutant homoduplex [Vossen, et al.,  
42  
43 2009]. In this study, we evaluated the sensitivity of different COLD PCR HRM assays for the  
44  
45 detection of *IDH1*<sup>R132H</sup> mutation in glioma samples.

## Material and methods

### DNA and tumors samples

Tumor samples were selected from the Pitié-Salpêtrière brain tumor database. Tumor DNA was extracted from frozen tissues using the QIAmp DNA according to the manufacturer instructions (Qiagen). Samples used in this work have previously been tested for the presence of *IDH1* mutation (reference sequence NM\_005896.2) by direct sequencing, as already described [Parsons, et al., 2008; Yan, et al., 2009].

### Determination of $T_c$

We applied the fast COLD PCR assays for detecting *IDH1* mutation based on the methodology described in the literature [Li, et al., 2008], with several modifications. We first determined the new denaturation temperature  $T_c$  for the reaction. We used the same primers as for conventional PCR assay, which produced an amplicon of 172 bp. To identify the optimal critical denaturation temperature  $T_c$ , a series of COLD PCR reactions at graded temperatures below  $T_m$  were performed. We then set the  $T_c$  at 81°C, the lowest temperature that reproducibly yielded a substantial PCR. In fast COLD PCR, the reaction protocol began with 20 cycles of conventional amplification for an initial build-up of all amplicons, followed by 30 COLD PCR cycles to selectively enrich for  $T_m$ -reduced mutant sequences (Figure 1). COLD PCR assays were performed on a LightCycler480 (Roche Diagnostics Corporation) to ensure a precise control of temperature during the experiments.

### Comparison of sensitivities of the different assays to detect *IDH1* mutation

To determine if COLD PCR could enhance the sensitivity of *IDH1*<sup>R132H</sup> mutation detection, we compared the sensitivity of three experimental protocols. Exon 4 of the *IDH1*

1  
2  
3 gene was first amplified either by conventional PCR or by fast COLD PCR. A second round  
4  
5 of amplification was then performed either by PCR HRM, or by fast COLD PCR HRM  
6  
7 (Figure 2).  
8  
9

10  
11  
12  
13  
14  
15 To compare the sensitivity of the different assays, we performed a serial dilution study  
16  
17 using a gDNA sample from a grade II oligoastrocytoma patient containing an *IDH1*<sup>R132H</sup>  
18  
19 mutation as the source of the mutant allele. This mutation-containing gDNA sample was  
20  
21 serially diluted into wild-type gDNA (ie blood constitutive gDNA from the same patient) to  
22  
23 the following percentages: 25%, 10%, 8%, 5%, 4%, 2%, 1%, 0.5%, 0.25%, 0.1%, and 0.05%.  
24  
25 In addition, wild-type gDNAs (n=7) were included in each experiment. The same experiment  
26  
27 was reproduced with several other mutated DNA samples: another CGT→CAT mutation  
28  
29 (Arg132His), and also with other, less frequent mutations, such as CGT→CTT (Arg132Leu)  
30  
31 and CGT→AGT (Arg132Ser).  
32

34  
35  
36  
37  
38

### 39 **First round of amplification**

40  
41  
42 Each PCR amplification reaction contained 50ng gDNA. PCR cycling conditions for  
43  
44 the first round consisted of an initial denaturation step at 94°C for 5 min; 40 cycles of 94°C  
45  
46 for 30s; 60°C for 1 min; and 72°C for 1 min30; and final extension at 72°C for 7 min. The  
47  
48 reactions were carried out using a Mastercycler (Eppendorf). Conventional PCR reactions  
49  
50 contained final reagent concentrations as follows: 1x PCR Master Mix (Abgene), 0.25 μM  
51  
52 forward and reverse primers (Invitrogen; Table I) and DNA template. COLD PCR cycling  
53  
54 conditions on LightCycler480 (Roche Diagnostics Corporation) are summarized as follows:  
55  
56 96°C, 10 min; 20 cycles of 95°C, 15s; 60°C, 30s, then 30 cycles of 81°C, 15s; 60°C, 30s.  
57  
58  
59  
60

1  
2  
3 COLD PCR assays contained final reagent concentrations as follows: LightCycler480 HRM  
4  
5 Master (Roche Diagnostics Corporation), 0.25  $\mu$ M forward and reverse primers (Invitrogen),  
6  
7  
8 3 mM MgCl<sub>2</sub> and DNA template.  
9

### 14 **Second round of amplification**

17  
18 PCR amplification was performed with the LightCycler480 (Roche Diagnostics  
19  
20 Corporation). Each reaction contained diluted PCR amplicons (1/1000), 0.25  $\mu$ M forward and  
21  
22 reverse primers (Invitrogen, Table I), 3 mM MgCl<sub>2</sub> and LightCycler480 HRM Master (Roche  
23  
24 Diagnostics Corporation). PCR HRM cycling conditions were as follows: 96°C, 10min; 40  
25  
26 cycles of 95°C, 30s; 60°C, 30s. COLD PCR HRM cycling conditions are summarized as  
27  
28 follows: 96°C , 10min; 20 cycles of 95°C, 15s; 60°C, 30s, then 30 cycles of 81°C (T<sub>c</sub>), 15s;  
29  
30 60°C, 30s. After amplification, a post amplification melting curve program was initiated by  
31  
32 heating to 95°C for 1 min, cooling to 40°C for 1 min, and increasing the temperature to 95°C  
33  
34 while continuously measuring fluorescence at 25 acquisitions per degree. Each PCR run  
35  
36 contained a negative (no template) control and each amplification was duplicated.  
37  
38  
39  
40  
41

### 42 **High Resolution Melting (HRM) analysis and direct sequencing**

45  
46 At the end of the second round of amplification, fluorescent melting curves were  
47  
48 analyzed using LC480 Gene Scanning software V1.2.9 (Roche Diagnostics Corporation). All  
49  
50 curves were analyzed following normalization, temperature shifting, automated grouping, and  
51  
52 the inspection of difference plots. The grouping software uses a curve shape-matching  
53  
54 algorithm in order to identify wild type from mutant samples. The 0.2 value was chosen for  
55  
56 the grouping sensitivity in all experiments.  
57  
58  
59  
60

1  
2  
3 Products of each assay were then submitted to the sequencing reaction using the  
4 BigDye Terminator v3.1 Sequencing Kit (Applied Biosystems) as previously described  
5 [Sanson, et al., 2009]. After a purification step using BigDye Xterminator Purification Kit  
6 (Applied Biosystems), both forward and reverse sequences were determined on an ABI prism  
7 3730 DNA analyzer (Perkin Elmer).

11  
12  
13  
14  
15

### 16 **Tumor sample selection and immunohistochemical detection of *IDH1*<sup>R132H</sup>**

17

18  
19 Tumors were retrieved from the neuropathology department database according to the  
20 following criteria: histological diagnosis of WHO grade II gliomas; presence of *IDH1*<sup>R132H</sup>  
21 mutation confirmed by Sanger sequencing; availability of frozen and paraffin embedded  
22 samples of tumor core and tumor edge, with edge biopsies considered as free of infiltrated  
23 tumor cells by standard HE staining.  
24  
25  
26  
27  
28  
29  
30

31  
32 Immunohistochemical staining for *IDH1*<sup>R132H</sup> was performed on 4 µm paraffin  
33 sections of formalin-fixed tumor samples using mouse monoclonal anti-R132H-IDH1  
34 antibody culture supernatant ( a generous gift from Pr A. von Deimling), as previously  
35 published [Capper, et al., 2010; Capper, et al., 2009]. Local immunohistochemistry protocol  
36 was validated on gliomas samples which were previously analysed by Sanger sequencing for  
37 *IDH1*<sup>R132H</sup> mutation (positive and negative controls). Labelling was defined as positive (at  
38 least one cluster of positive tumor cells) or negative (no positive tumor cells detected).

## Results

### Determination of the sensitivity with dilution studies

To identify the most sensitive method for detecting *IDHI* mutation, we evaluated two techniques after a first stage of conventional PCR: the PCR HRM assay and the COLD PCR HRM assay. In a third assay, we replaced the first conventional PCR by a run of COLD PCR (Figure 2). The sensitivity of the three assays was compared using a dilution series obtained by mixing DNA from heterozygous positive control carrying the *IDHI* R132H mutation with wild-type DNA from peripheral blood.

Conventional PCR HRM assay detects mutant DNA at a concentration of 25% in a background of wild-type DNA (Figure 3A). In contrast, the COLD PCR HRM assay detects *IDHI*<sup>R132H</sup> mutation at a much lower concentration: mutant DNA diluted into wild-type DNA to a 2% abundance was still clearly differentiated from normal sequences (Figure 3B). Therefore, the COLD PCR HRM assay produced an approximately 10-fold improvement in the *IDHI* mutation detection, as compared to the conventional PCR HRM analysis. Replacing the first conventional PCR amplification by a run of COLD PCR further enhanced selective enrichment of the mutant DNA and improved the detection of *IDHI*<sup>R132H</sup> mutation. In these conditions, we were able to detect mutant DNA at a concentration as low as 0.25% in mixture with wild-type DNA (Figure 3C). Thus, the double COLD PCR HRM assay for the detection of *IDHI*<sup>R132H</sup> mutation was 100-fold more sensitive than the PCR HRM assay.

To both confirm the selective mutation enrichment and to exclude false positive results, amplicons produced at the end of the three assays were submitted to direct sequencing using the Sanger method. The sequencing chromatograms are presented in Figure 3D. In all three cases, direct sequencing confirmed the presence of the *IDHI*<sup>R132H</sup> mutation. After

1  
2  
3 double COLD PCR HRM with 0.25% of mutant DNA/wild DNA, *IDH1*<sup>R132H</sup> mutation was  
4  
5 evident as clearly as for 25% with conventional PCR HRM and 2% with COLD PCR HRM.  
6  
7

8  
9 The same results were obtained with another glioma with CGT→CAT mutation (Arg132His),  
10  
11 and also with less frequent *IDH1*<sup>132</sup> mutations CGT→CTT (Arg132Leu) and CGT→AGT  
12  
13 (Arg132Ser) (supplementary figure).

26 To definitely validate the clinical interest of our technique, we selected 10 pairs of  
27  
28 tumor core and tumor edge (one astrocytoma, 5 oligodendrogliomas, and 4  
29  
30 oligoastrocytomas), and performed *IDH1*<sup>R132H</sup> mutation detection by both  
31  
32 immunohistochemistry and molecular techniques (Table II). *IDH1*<sup>R132H</sup>  
33  
34 immunohistochemistry was positive in 3 cases (30%, 2 grade II oligodendrogliomas, and one  
35  
36 grade II oligoastrocytoma) showing a cytoplasmic granular staining as previously described  
37  
38 [Capper, et al., 2010]. Figure 4A presents the results of immunohistochemistry staining for  
39  
40 patient 8 in the tumor core and in the biopsy edge (lower panel). PCR HRM was positive in 8  
41  
42 cases out of 10 (80.0%; Figure 4B upper panel). In contrast, both COLD PCR HRM (data not  
43  
44 shown) and double COLD PCR HRM were positive in all cases (100%; Figure 4B, lower  
45  
46 panel, and table II).

## Discussion

Gliomas are characterized by a highly invasive phenotype, with tumor cells invading the brain at a distance far from the bulk of tumor [Furnari, et al., 2007]. Therefore biopsy samples are often contaminated by normal brain tissue, and mutated DNA is diluted in a the background of wild-type DNA from surrounding brain tissue, vasculature, and infiltrating lymphocytes [Dobrowolski, et al., 2009]. Because *IDH1*<sup>R132H</sup> mutation is almost restricted to gliomas [Yan, et al., 2009], it has a major diagnostic potential. Therefore a fast and reliable scanning technique to detect this mutation in clinical samples with very few tumor cells (and appearing therefore normal at neuropathological analysis) is particularly important. In addition *IDH1*<sup>R132H</sup> mutation is a major prognostic factor [Sanson, et al., 2009; van den Bent, et al., 2010]. Simple HRM has been very recently reported as a fast and sensitive strategy, detecting IDH1 and IDH2 mutations in a 90% normal DNA background [Horbinski, et al., 2010]. In this study, we used fast COLD PCR to selectively amplify *IDH1*<sup>R132H</sup> mutated DNA and we showed that double COLD PCR HRM assay is a highly reliable method to detect *IDH1* mutation in samples with very few tumor cells (up to 0.25% mutated/non mutated DNA). In addition, this assay is fast (less than three hours) and therefore particularly suitable for routine diagnosis purposes in neuropathology.

Despite *IDH1*<sup>R132H</sup> accounts for more than 90% of *IDH1* mutations reported in gliomas, other mutations have been described: CGT→AGT, CGT→CTT CGT→GGT, CGT→TGT [Balss, et al., 2008; Gravendeel, et al., 2010; Sanson, et al., 2009; Yan, et al., 2009]. Fortunately, all these mutations, except the CGT→GGT change, result in a lower T<sub>m</sub>, rendering them theoretically detectable by our simple double COLD PCR assay. Indeed we were able to detect some of these less frequent mutations (supplementary figure). For the detection of CGT→GGT, a full COLD PCR assay –allowing the enrichment of all possible

1  
2  
3 mutations- could be performed, though the selective amplification *ratio* will probably be  
4  
5 lower than in fast COLD PCR, because amplification, and thus enrichment in mutant  
6  
7 sequences, begins earlier during cycling in fast COLD PCR than in full COLD PCR [Li, et al.,  
8  
9 2008; Milbury, et al., 2009].  
10  
11

12  
13 We showed that double COLD PCR HRM (followed by sequencing in case of aberrant  
14  
15 HRM profiles) is a powerful method to evidence the presence of tumor cells with IDH1  
16  
17 mutation in apparently “blank” biopsies of grade II gliomas, and is much more sensitive than  
18  
19 immunohistochemistry for *IDH1*<sup>R132H</sup>. Such procedure may be particularly useful in lesions  
20  
21 radiologically highly suggestive of glioma, whose biopsy appears non contributive because of  
22  
23 the very low proportion of tumor cells. In such cases, finding an *IDH1* mutation will confirm  
24  
25 the diagnosis of glioma, avoiding a further invasive procedure to establish diagnosis.  
26  
27 Moreover, such approach could also be suitable for *IDH1*<sup>R132H</sup> mutation detection in the  
28  
29 cerebral spinal fluid thus confirming glioma diagnosis without the need for surgery.

## Abstract

Isocitrate dehydrogenase 1 R132H (*IDHI*<sup>R132H</sup>) mutation is a frequent alteration and a major prognostic marker in gliomas. However, direct sequencing of highly contaminated tumor samples may fail to detect this mutation. Our objective was to evaluate the sensitivity of a newly described amplification method, coamplification at lower temperature-PCR (COLD PCR), combined with high resolution melting (HRM) for the detection of *IDHI*<sup>R132H</sup> mutation. To this end, we used serial dilutions of mutant DNA with wild type DNA. PCR-HRM assay detects *IDHI*<sup>R132H</sup> mutation at an abundance of 25%, similar to the detection limit of direct Sanger sequencing. Introducing a run of COLD PCR allows the detection of 2% mutant DNA. Using two consecutive runs of COLD PCR, we detected 0.25% mutant DNA in a background of wild type DNA, that mimicks a tumor sample highly contaminated by normal DNA. We then analyzed ten biopsies of tumor edges, considered free of tumor cells by histological analysis, and showed that immunohistochemistry of *IDHI*<sup>R132H</sup> was positive in 3 cases (30%), whereas double COLD PCR HRM was positive in the ten cases studied (100%). In summary, COLD PCR HRM analysis is 100-fold more sensitive than Sanger sequencing, rendering this rapid and powerful strategy particularly useful for samples highly contaminated with normal tissue.

**Keywords:** *IDHI*<sup>R132H</sup> mutation, COLD PCR, High Resolution Melting, glioma

## Introduction

In recent years, recurrent mutations of the gene encoding isocitrate dehydrogenase 1 (*IDH1*; MIM# 147700) have been described at a high frequency in gliomas [Balss, et al., 2008; Bleeker, et al., 2009; Hartmann, et al., 2009; Ichimura, et al., 2009; Parsons, et al., 2008; Sanson, et al., 2009; Yan, et al., 2009]. Mutations in the *IDH1* gene always affect the codon 132, which in more than 90% of cases result in a substitution of arginine by a histidine residue, *IDH1*<sup>R132H</sup> [Ichimura, et al., 2009; Sanson, et al., 2009; Yan, et al., 2009]. Since it is almost exclusively found in gliomas, *IDH1* mutation has a strong diagnostic value [Yan, et al., 2009]. *IDH1* mutation is also a powerful independent prognostic factor in gliomas [Dubink, et al., 2009; Nobusawa, et al., 2009; Sanson, et al., 2009]: patients with an *IDH1*<sup>R132H</sup> mutated tumor having a longer survival when compared with those non mutated for the same grade. Given its diagnostic and prognostic potential, the determination of *IDH1* status in glioma samples is gaining increasing attention in clinical practice.

Conventional PCR followed by Sanger sequencing is currently the gold standard in identifying *IDH1* mutations in tumor DNA. Typically, clinical tumor samples are contaminated by normal tissue, thereby diluting the total amount of genetic that is present, and techniques are often required to identify low level alterations within an excess of wild-type DNA. This is particularly true for gliomas which are highly infiltrating tumors [Furnari, et al., 2007]. Conventional PCR enables mutation detection from a very small amount of sample but does not selectively amplify the mutant sequences. Therefore, unless the mutation exceeds a 20-25% abundance relative to wild-type alleles, conventional PCR followed by downstream methods such as Sanger sequencing will fail to detect mutations in clinical samples [Li, et al., 2009; Zuo, et al., 2009]. Enrichment methods are thus necessary to increase the mutant DNA /wild type DNA *ratio*. Tumor-cell enrichment methods, such as cell

1  
2  
3 sorting or microdissection, are expensive and time-consuming [Zuo, et al., 2009], and  
4  
5 therefore inadequate for clinical routine use.  
6  
7

8  
9 Recently, co-amplification at lower denaturation temperature PCR (COLD PCR) has  
10  
11 been described as a powerful method to identify low-level mutations in the *TP53* gene [Li, et  
12  
13 al., 2008; Milbury, et al., 2009]. This approach uses a critical temperature ( $T_c$ ) during the  
14  
15 PCR process in order to enrich mutations at any position of the amplified sequence. Indeed, a  
16  
17 single nucleotide mismatch anywhere along a double-stranded DNA sequence generates a  
18  
19 small change in the melting temperature for that sequence, with mutated sequences melting at  
20  
21 a lower temperature than wild-type sequences [Li, et al., 2008]. During COLD PCR, the  
22  
23 denaturation temperature is set to  $T_c$ , thereby mutation-containing sequences are  
24  
25 preferentially denatured and available for primers binding and subsequent amplification. High  
26  
27 Resolution DNA Melting (HRM) analysis is a relatively new and rapid method for detecting  
28  
29 DNA sequence variants following an initial amplification [Erali, et al., 2008; Vossen, et al.,  
30  
31 2009; Wittwer, 2009]. Gene scanning by HRM depends on the recognition of changes in the  
32  
33 shape of the amplicon melting curve that result from heterozygous sequence alterations [Erali,  
34  
35 et al., 2008]. At the end of PCR amplification, samples are heated to 95°C to ensure a  
36  
37 complete denaturation. Next, the temperature is reduced to allow cross-hybridization between  
38  
39 wild-type and mutant sequences, leading to the formation of mismatched heteroduplexes,  
40  
41 which melt at a lower temperature than wild-type and mutant homoduplex [Vossen, et al.,  
42  
43 2009]. In this study, we evaluated the sensitivity of different COLD PCR HRM assays for the  
44  
45 detection of **IDH1<sup>R132H</sup>** mutation in glioma samples.

## Material and methods

### DNA and tumors samples

Tumor samples were selected from the Pitié-Salpêtrière brain tumor database. Tumor DNA was extracted from frozen tissues using the QIAmp DNA according to the manufacturer instructions (Qiagen). Samples used in this work have previously been tested for the presence of *IDH1* mutation (reference sequence NM\_005896.2) by direct sequencing, as already described [Parsons, et al., 2008; Yan, et al., 2009].

### Determination of $T_c$

We applied the fast COLD PCR assays for detecting *IDH1* mutation based on the methodology described in the literature [Li, et al., 2008], with several modifications. We first determined the new denaturation temperature  $T_c$  for the reaction. We used the same primers as for conventional PCR assay, which produced an amplicon of 172 bp. To identify the optimal critical denaturation temperature  $T_c$ , a series of COLD PCR reactions at graded temperatures below  $T_m$  were performed. We then set the  $T_c$  at 81°C, the lowest temperature that reproducibly yielded a substantial PCR. In fast COLD PCR, the reaction protocol began with 20 cycles of conventional amplification for an initial build-up of all amplicons, followed by 30 COLD PCR cycles to selectively enrich for  $T_m$ -reduced mutant sequences (Figure 1). COLD PCR assays were performed on a LightCycler480 (Roche Diagnostics Corporation) to ensure a precise control of temperature during the experiments.

### Comparison of sensitivities of the different assays to detect *IDH1* mutation

To determine if COLD PCR could enhance the sensitivity of *IDH1*<sup>R132H</sup> mutation detection, we compared the sensitivity of three experimental protocols. Exon 4 of the *IDH1*

1  
2  
3 gene was first amplified either by conventional PCR or by fast COLD PCR. A second round  
4  
5 of amplification was then performed either by PCR HRM, or by fast COLD PCR HRM  
6  
7 (Figure 2).  
8  
9

10  
11  
12  
13  
14 To compare the sensitivity of the different assays, we performed a serial dilution study  
15  
16 using a gDNA sample from a grade II oligoastrocytoma patient containing an *IDH1*<sup>R132H</sup>  
17  
18 mutation as the source of the mutant allele. This mutation-containing gDNA sample was  
19  
20 serially diluted into wild-type gDNA (ie blood constitutive gDNA from the same patient) to  
21  
22 the following percentages: 25%, 10%, 8%, 5%, 4%, 2%, 1%, 0.5%, 0.25%, 0.1%, and 0.05%.  
23  
24 In addition, wild-type gDNAs (n=7) were included in each experiment. The same experiment  
25  
26 was reproduced with several other mutated DNA samples: another CGT→CAT mutation  
27  
28 (Arg132His), and also with other, less frequent mutations, such as CGT→CTT (Arg132Leu)  
29  
30 and CGT→AGT (Arg132Ser).

### 39 First round of amplification

40  
41  
42 Each PCR amplification reaction contained 50ng gDNA. PCR cycling conditions for  
43  
44 the first round consisted of an initial denaturation step at 94°C for 5 min; 40 cycles of 94°C  
45  
46 for 30s; 60°C for 1 min; and 72°C for 1 min30; and final extension at 72°C for 7 min. The  
47  
48 reactions were carried out using a Mastercycler (Eppendorf). Conventional PCR reactions  
49  
50 contained final reagent concentrations as follows: 1x PCR Master Mix (Abgene), 0.25 μM  
51  
52 forward and reverse primers (Invitrogen; Table I) and DNA template. COLD PCR cycling  
53  
54 conditions on LightCycler480 (Roche Diagnostics Corporation) are summarized as follows:  
55  
56 96°C, 10 min; 20 cycles of 95°C, 15s; 60°C, 30s, then 30 cycles of 81°C, 15s; 60°C, 30s.  
57  
58  
59  
60

1  
2  
3 COLD PCR assays contained final reagent concentrations as follows: LightCycler480 HRM  
4  
5 Master (Roche Diagnostics Corporation), 0.25  $\mu$ M forward and reverse primers (Invitrogen),  
6  
7  
8 3 mM MgCl<sub>2</sub> and DNA template.  
9

### 10 11 12 13 14 **Second round of amplification** 15

16  
17  
18 PCR amplification was performed with the LightCycler480 (Roche Diagnostics  
19 Corporation). Each reaction contained diluted PCR amplicons (1/1000), 0.25  $\mu$ M forward and  
20 reverse primers (Invitrogen, Table I), 3 mM MgCl<sub>2</sub> and LightCycler480 HRM Master (Roche  
21 Diagnostics Corporation). PCR HRM cycling conditions were as follows: 96°C, 10min; 40  
22 cycles of 95°C, 30s; 60°C, 30s. COLD PCR HRM cycling conditions are summarized as  
23 follows: 96°C , 10min; 20 cycles of 95°C, 15s; 60°C, 30s, then 30 cycles of 81°C (T<sub>c</sub>), 15s;  
24 60°C, 30s. After amplification, a post amplification melting curve program was initiated by  
25 heating to 95°C for 1 min, cooling to 40°C for 1 min, and increasing the temperature to 95°C  
26 while continuously measuring fluorescence at 25 acquisitions per degree. Each PCR run  
27 contained a negative (no template) control and each amplification was duplicated.

### 42 **High Resolution Melting (HRM) analysis and direct sequencing** 43 44

45  
46 At the end of the second round of amplification, fluorescent melting curves were  
47 analyzed using LC480 Gene Scanning software V1.2.9 (Roche Diagnostics Corporation). All  
48 curves were analyzed following normalization, temperature shifting, automated grouping, and  
49 the inspection of difference plots. The grouping software uses a curve shape-matching  
50 algorithm in order to identify wild type from mutant samples. The 0.2 value was chosen for  
51 the grouping sensitivity in all experiments.

### 15 16 **Tumor sample selection and immunohistochemical detection of *IDH1*<sup>R132H</sup>**

17  
18  
19 Tumors were retrieved from the neuropathology department database according to the  
20 following criteria: histological diagnosis of WHO grade II gliomas; presence of *IDH1*<sup>R132H</sup>  
21 mutation confirmed by Sanger sequencing; availability of frozen and paraffin embedded  
22 samples of tumor core and tumor edge, with edge biopsies considered as free of infiltrated  
23 tumor cells by standard HE staining.  
24  
25  
26  
27  
28  
29  
30

31  
32 Immunohistochemical staining for *IDH1*<sup>R132H</sup> was performed on 4 µm paraffin  
33 sections of formalin-fixed tumor samples using mouse monoclonal anti-R132H-IDH1  
34 antibody culture supernatant ( a generous gift from Pr A. von Deimling), as previously  
35 published [Capper, et al., 2010; Capper, et al., 2009]. Local immunohistochemistry protocol  
36 was validated on gliomas samples which were previously analysed by Sanger sequencing for  
37 *IDH1*<sup>R132H</sup> mutation (positive and negative controls). Labelling was defined as positive (at  
38 least one cluster of positive tumor cells) or negative (no positive tumor cells detected).

## Results

### Determination of the sensitivity with dilution studies

To identify the most sensitive method for detecting *IDH1* mutation, we evaluated two techniques after a first stage of conventional PCR: the PCR HRM assay and the COLD PCR HRM assay. In a third assay, we replaced the first conventional PCR by a run of COLD PCR (**Figure 2**). The sensitivity of the three assays was compared using a dilution series obtained by mixing DNA from heterozygous positive control carrying the *IDH1* R132H mutation with wild-type DNA from peripheral blood.

Conventional PCR HRM assay detects mutant DNA at a concentration of 25% in a background of wild-type DNA (**Figure 3A**). In contrast, the COLD PCR HRM assay detects *IDH1*<sup>R132H</sup> mutation at a much lower concentration: mutant DNA diluted into wild-type DNA to a 2% abundance was still clearly differentiated from normal sequences (**Figure 3B**). Therefore, the COLD PCR HRM assay produced an approximately 10-fold improvement in the *IDH1* mutation detection, as compared to the conventional PCR HRM analysis. Replacing the first conventional PCR amplification by a run of COLD PCR further enhanced selective enrichment of the mutant DNA and improved the detection of *IDH1*<sup>R132H</sup> mutation. In these conditions, we were able to detect mutant DNA at a concentration as low as 0.25% in mixture with wild-type DNA (**Figure 3C**). Thus, the double COLD PCR HRM assay for the detection of *IDH1*<sup>R132H</sup> mutation was 100-fold more sensitive than the PCR HRM assay.

To both confirm the selective mutation enrichment and to exclude false positive results, amplicons produced at the end of the three assays were submitted to direct sequencing using the Sanger method. The sequencing chromatograms are presented in Figure 3D. In all three cases, direct sequencing confirmed the presence of the *IDH1*<sup>R132H</sup> mutation. After

1  
2  
3 double COLD PCR HRM with 0.25% of mutant DNA/wild DNA, *IDH1*<sup>R132H</sup> mutation was  
4  
5 evident as clearly as for 25% with conventional PCR HRM and 2% with COLD PCR HRM.  
6  
7

8  
9 The same results were obtained with another glioma with **CGT→CAT mutation**  
10  
11 **(Arg132His), and also with less frequent *IDH1*<sup>132</sup> mutations CGT→CTT (Arg132Leu)**  
12  
13 **and CGT→AGT (Arg132Ser) (supplementary figure).**  
14

### 16 17 18 19 20 **Comparison of PCR HRM, COLD PCR HRM and double COLD PCR HRM and** 21 22 ***IDH1*<sup>R132H</sup> immunohistochemistry in biopsies of tumor edges** 23 24

25  
26 To definitely validate the clinical interest of our technique, we selected 10 pairs of  
27  
28 tumor core and tumor edge (one astrocytoma, 5 oligodendrogliomas, and 4  
29  
30 oligoastrocytomas), and performed *IDH1*<sup>R132H</sup> mutation detection by both  
31  
32 immunohistochemistry and molecular techniques (**Table II**). *IDH1*<sup>R132H</sup>  
33  
34 immunohistochemistry was positive in 3 cases (30%, 2 grade II oligodendrogliomas, and one  
35  
36 grade II oligoastrocytoma) showing a cytoplasmic granular staining as previously described  
37  
38 [Capper, et al., 2010]. **Figure 4A** presents the results of immunohistochemistry staining for  
39  
40 patient 8 in the tumor core and in the biopsy edge (lower panel). PCR HRM was positive in 8  
41  
42 cases out of 10 (80.0%; **Figure 4B** upper panel). In contrast, both COLD PCR HRM (data not  
43  
44 shown) and double COLD PCR HRM were positive in all cases (100%; **Figure 4B**, lower  
45  
46 panel, and **table II**).

## Discussion

Gliomas are characterized by a highly invasive phenotype, with tumor cells invading the brain at a distance far from the bulk of tumor [Furnari, et al., 2007]. Therefore biopsy samples are often contaminated by normal brain tissue, and mutated DNA is diluted in a the background of wild-type DNA from surrounding brain tissue, vasculature, and infiltrating lymphocytes [Dobrowolski, et al., 2009]. Because *IDH1*<sup>R132H</sup> mutation is almost restricted to gliomas [Yan, et al., 2009], it has a major diagnostic potential. Therefore a fast and reliable scanning technique to detect this mutation in clinical samples with very few tumor cells (and appearing therefore normal at neuropathological analysis) is particularly important. In addition *IDH1*<sup>R132H</sup> mutation is a major prognostic factor [Sanson, et al., 2009; van den Bent, et al., 2010]. Simple HRM has been very recently reported as a fast and sensitive strategy, detecting IDH1 and IDH2 mutations in a 90% normal DNA background [Horbinski, et al., 2010]. In this study, we used fast COLD PCR to selectively amplify *IDH1*<sup>R132H</sup> mutated DNA and we showed that double COLD PCR HRM assay is a highly reliable method to detect *IDH1* mutation in samples with very few tumor cells (up to 0.25% mutated/non mutated DNA). In addition, this assay is fast (less than three hours) and therefore particularly suitable for routine diagnosis purposes in neuropathology.

Despite *IDH1*<sup>R132H</sup> accounts for more than 90% of *IDH1* mutations reported in gliomas, other mutations have been described: CGT→AGT, CGT→CTT CGT→GGT, CGT→TGT [Balss, et al., 2008; Gravendeel, et al., 2010; Sanson, et al., 2009; Yan, et al., 2009]. Fortunately, all these mutations, except the CGT→GGT change, result in a lower T<sub>m</sub>, rendering them theoretically detectable by our simple double COLD PCR assay. Indeed we were able to detect some of these less frequent mutations (supplementary figure). For the detection of CGT→GGT, a full COLD PCR assay –allowing the enrichment of all possible

1  
2  
3 mutations- could be performed, though the selective amplification *ratio* will probably be  
4  
5 lower than in fast COLD PCR, because amplification, and thus enrichment in mutant  
6  
7 sequences, begins earlier during cycling in fast COLD PCR than in full COLD PCR [Li, et al.,  
8  
9 2008; Milbury, et al., 2009].  
10  
11

12  
13 We showed that double COLD PCR HRM (followed by sequencing in case of aberrant  
14  
15 HRM profiles) is a powerful method to evidence the presence of tumor cells with IDH1  
16  
17 mutation in apparently “blank” biopsies of grade II gliomas, and is much more sensitive than  
18  
19 immunohistochemistry for *IDH1*<sup>R132H</sup>. Such procedure may be particularly useful in lesions  
20  
21 radiologically highly suggestive of glioma, whose biopsy appears non contributive because of  
22  
23 the very low proportion of tumor cells. In such cases, finding an *IDH1* mutation will confirm  
24  
25 the diagnosis of glioma, avoiding a further invasive procedure to establish diagnosis.  
26  
27 Moreover, such approach could also be suitable for *IDH1*<sup>R132H</sup> mutation detection in the  
28  
29 cerebral spinal fluid thus confirming glioma diagnosis without the need for surgery.

**Table I:** Primers used for first and second rounds of amplification

	<b>Primer</b>	<b>Amplicon length</b>
<b>First amplification</b>	Forward	CGGTCTTCAGAGAAGCCATT
	Reverse	CACATACAAGTTGGAAATTTCTGG
<b>Second amplification</b>	Forward	CGGTCTTCAGAGAAGCCATT
	Reverse	GCAAAATCACATTATTGCCAAC

**Table II: Comparison of IDH1<sup>R132</sup> immunohistochemistry with PCR HRM and double COLD PCR HRM for the detection of IDH1<sup>R132H</sup> mutation in tumor edges.** For all techniques, results are expressed as positive (+) or negative (-). COLD PCR HRM (data not shown) gave the same results as double COLD PCR HRM.

Patients	Histology	IDH1 <sup>R132</sup> immunohistochemistry		PCR HRM		Double COLD PCR HRM	
		Tumor core	Tumor edge	Tumor core	Tumor edge	Tumor core	Tumor edge
1	OAI	+	-	+	+	+	+
2	OII	+	-	+	-	+	+
3	AI	+	-	+	+	+	+
4	OAI	+	-	+	+	+	+
5	OAI	+	+	+	+	+	+
6	OII	+	-	+	+	+	+
7	OII	+	+	+	+	+	+
8	OII	+	+	+	+	+	+
9	OAI	+	-	+	+	+	+
10	OII	+	-	+	-	+	+

All: grade II oligoastrocytoma; OAI: oligoastrocytoma; OII: oligodendroglioma.
