**Abstract.** In this paper, a decomposition method for Tobit-models is derived, which allows the differences in observed outcome variables between two groups to be decomposed into a part that is explained by differences in observed characteristics and a part attributable to differences in the estimated coefficients. Monte Carlo simulations demonstrate that in the case of censored dependent variables this decomposition method produces more reliable results than the conventional Blinder-Oaxaca decomposition for linear regression models. Finally, our method is applied to a decomposition of the gender wage gap using German data.

**JEL-Classification:** C24, J31

**Keywords:** Blinder-Oaxaca decomposition, Tobit model, gender wage gap

# 1 Introduction

The decomposition method developed by Blinder (1973) and Oaxaca (1973) and generalized by Juhn, Murphy, and Pierce (1991), Neumark (1988), and Oaxaca and Ransom (1988, 1994) is a very popular descriptive tool, since it permits the decomposition of the difference in an outcome variable between two groups into a part that is explained by differences in the observed characteristics of these groups and a part that is due to differences in the estimated coefficients.

So far, the Blinder-Oaxaca-decomposition and its various generalizations have mainly been used in linear regression models. A decomposition method for models with binary dependent variables has been developed by Fairlie (1999, 2003). In many cases, however, censoring requires the estimation of a Tobit-model because OLS yields inconsistent parameter estimates and in turn misleading decomposition results. In this paper, a Blinder-Oaxaca type decomposition method for Tobit-models is derived. To compare the results obtained from this method to the results obtained when the conventional Blinder-Oaxaca decomposition method for linear regression models is used despite a censored dependent variable, a Monte Carlo simulation is carried out. Finally, our method is applied to a decomposition of the gender wage gap using data from the German *Socio-Economic Panel* (SOEP).

## 2 Blinder-Oaxaca Decomposition for Tobit Models

Consider the following linear regression model, which is estimated separately for the groups  $g = m, f$

$$Y_{ig} = X_{ig}\beta_g + \varepsilon_{ig}, \quad (1)$$

for  $i = 1, \dots, N_g$ , and  $\sum_g N_g = N$ . For these models, Blinder (1973) and Oaxaca (1973) propose the decomposition

$$\begin{aligned} \bar{Y}_m - \bar{Y}_f &= \Delta^{OLS} = [E_{\beta_m}(Y_{im} | X_{im}) - E_{\beta_m}(Y_{if} | X_{if})] \\ &\quad + [E_{\beta_m}(Y_{if} | X_{if}) - E_{\beta_f}(Y_{if} | X_{if})] \\ &= (\bar{X}_m - \bar{X}_f)\hat{\beta}_m + \bar{X}_f(\hat{\beta}_m - \hat{\beta}_f), \end{aligned} \quad (2)$$

where  $\bar{Y}_g = N_g^{-1} \sum_{i=1}^{N_g} Y_{ig}$  and  $\bar{X}_g = N_g^{-1} \sum_{i=1}^{N_g} X_{ig}$ .  $E_{\beta_g}(Y_{ig} | X_{ig})$  refers to the conditional expectation of  $Y_{ig}$  evaluated at the parameter vector  $\beta_g$ . The first term on the right

hand side of equation (2) displays the difference in the outcome variable between the two groups due to differences in observable characteristics. The second term shows the differential that is due to differences in coefficient estimates.<sup>1 2</sup>

Given  $X_{ig}$ , the linear model is a good approximation of the expected value of the outcome variable  $E(Y_{ig}|X_{ig})$  for values of  $X_{ig}$  close to the mean. If the outcome variable  $Y_{ig}$  is censored, however, the use of OLS may lead to biased estimates of the parameter vector and hence misleading results of the decomposition. To illustrate the Blinder-Oaxaca decomposition in the presence of censoring, we consider a Tobit model, where the dependent variable takes on the values  $a_1$  and  $a_2$  with positive probability and represents a continuous random variable over values between  $a_1$  and  $a_2$ , i.e.

$$\begin{aligned}
 Y_{ig}^* &= X_{ig}\beta_g + \varepsilon_{ig}, \\
 Y_{ig} &= a_1 \quad \text{if } Y_{ig}^* \leq a_1 \\
 Y_{ig} &= a_2 \quad \text{if } Y_{ig}^* \geq a_2 \\
 Y_{ig} &= Y_{ig}^* = X_{ig}\beta_g + \varepsilon_{ig} \quad \text{if } a_1 < Y_{ig}^* < a_2, \\
 \varepsilon_{ig} &\square N(0, \sigma_g^2).
 \end{aligned} \tag{3}$$

Given that we are interested in the marginal effects of the latent censored outcome variable,  $\partial E(Y_{ig}^* | X_{ig}) / \partial X_{ig} = \beta_g$ , a solution to this problem would be the use of the Tobit estimator in the standard Blinder-Oaxaca decomposition of equation (2). However, the conventional decomposition method leads to erroneous predictions of the components of the decomposition equation if we aim at analyzing the observed outcome variable  $Y_i$  instead of the unobserved counterpart  $Y_i^*$ , i.e. the parameters of interest are given by the marginal effects of the observed outcome

<sup>1</sup> Based on this decomposition, Fairlie (1999, 2003) develops the following decomposition equation for models with binary dependent variables:  $\bar{Y}_m - \bar{Y}_f = [F(X_{im}\beta_m) - F(X_{if}\beta_m)] + [F(X_{if}\beta_m) - F(X_{if}\beta_f)]$ , where  $F(\cdot)$  is the cumulative distribution function (a logistic distribution is assumed for a Logit model and a standard normal distribution for a Probit model).

<sup>2</sup> Oaxaca and Ransom (1994) demonstrate that this decomposition may be considered as a special case of the decomposition  $\bar{Y}_m - \bar{Y}_f = (\bar{X}_m - \bar{X}_f)\hat{\beta}^* + \bar{X}_m(\hat{\beta}_m - \hat{\beta}^*) + \bar{X}_f(\hat{\beta}^* - \hat{\beta}_f)$ , where  $\hat{\beta}^* = \Omega_\beta \hat{\beta}_m + (I - \Omega_\beta)\hat{\beta}_f$  and  $\Omega_\beta$  is equal to the identity matrix  $I$ . A consideration of equation (2), however, is sufficient for the derivation of the decomposition method for Tobit-models. The generalization of the decomposition method to the equation proposed by Oaxaca and Ransom (1994) is straightforward.

variable,  $\partial E(Y_{ig} | X_{ig}) / \partial X_{ig} = \Phi(\beta_g, X_g, \sigma_g) \beta_g$ , where  $\Phi(\cdot)$  represents the cumulative standard normal density function. In this case, an alternative decomposition method must be applied.

Assuming homoscedastic and normally distributed error terms  $\varepsilon_{ig}$ , the unconditional expectation of  $Y_{ig}$  given  $X_{ig}$  consists of the conditional expectations of  $Y_{ig}$  weighted with the respective probabilities of observing  $a_1$ ,  $a_2$ , or a value between  $a_1$  and  $a_2$ :

$$E(Y_{ig} | X_{ig}) = a_1 \Phi_1(\beta_g, X_g, \sigma_g) + a_2 \Phi_2(\beta_g, X_g, \sigma_g) + \Lambda(\beta_g, X_g, \sigma_g) \left[ X_{ig} \beta_g + \sigma \frac{\lambda(\beta_g, X_g, \sigma_g)}{\Lambda(\beta_g, X_g, \sigma_g)} \right], \quad (4)$$

where  $\Phi_1(\beta_g, X_g, \sigma_g) = \Phi[\sigma_g^{-1}(a_1 - X_{ig} \beta_g)]$ ,  $\Phi_2(\beta_g, X_g, \sigma_g) = 1 - \Phi[\sigma_g^{-1}(a_2 - X_{ig} \beta_g)]$ ,  $\Lambda(\cdot) = \Phi_2(\cdot) - \Phi_1(\cdot)$  and  $\lambda(\beta_g, X_g, \sigma_g) = \varnothing[\sigma_g^{-1}(a_1 - X_{ig} \beta_g)] - \varnothing[\sigma_g^{-1}(a_2 - X_{ig} \beta_g)]$ ;  $\varnothing(\cdot)$  represents the standard normal density function.

Equation (4) shows that a decomposition of the outcome variable similar to equation (2) is not appropriate for the observed outcome variable of the Tobit-model, because the conditional expectations  $E(Y_{ig} | X_{ig})$  in the Tobit-model depend on the standard error  $\sigma_g$ . Even though the ancillary parameter  $\sigma_g$  does not affect the sign of the marginal effects, it affects their magnitudes and therefore becomes important for the decomposition. Depending on which  $\sigma_g$  is used in the counterfactual parts of the decomposition equation, several possibilities of decomposing the mean difference of  $Y_i$  between the two groups can be derived. Two possibilities are

$$\Delta_f^{Tobit} = [E_{\beta_m, \sigma_m}(Y_{im} | X_{im}) - E_{\beta_m, \sigma_f}(Y_{if} | X_{if})] + [E_{\beta_m, \sigma_f}(Y_{if} | X_{if}) - E_{\beta_f, \sigma_f}(Y_{if} | X_{if})], \quad (5)$$

$$\Delta_m^{Tobit} = [E_{\beta_m, \sigma_m}(Y_{im} | X_{im}) - E_{\beta_m, \sigma_m}(Y_{if} | X_{if})] + [E_{\beta_m, \sigma_m}(Y_{if} | X_{if}) - E_{\beta_f, \sigma_f}(Y_{if} | X_{if})], \quad (6)$$

where  $E_{\beta_v, \sigma_v}(Y_{ig} | X_{ig})$  now refers to the conditional expectation of  $Y_{ig}$  evaluated at the parameter vector  $\beta_g$  and the standard error  $\sigma_g$ . In both equations, the first term on the right hand side displays the part of the differential in the outcome variable between the two groups that is due to differences in the covariates  $X_{ig}$ , and the second term the part of the differential in  $Y_{ig}$  that is due to differences in

coefficients.

The two versions of the decomposition equation may differ from each other, if large differences in the variance of the error term between the two groups exist. Note however, that the decomposition using  $\sigma_f$  to calculate the counterfactual parts, as in equation (5), is more comparable to the OLS decomposition described in equation (2), since the counterfactual parts differ from  $E_{\beta_f, \sigma_f}(Y_{if} | X_{if})$  only by using the parameter vector for group  $m$ ,  $\beta_m$ , rather than by using the parameter vector *and* the standard error for group  $m$  in the alternative decomposition described in equation (6).

Defining the sample counterpart  $S(\cdot)$  of equation (4),

$$S(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g) \equiv N^{-1} \sum_{i=1}^N \left\{ a_1 \Phi_1(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g) + a_2 \Phi_2(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g) + \Lambda(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g) \left[ X_{ig} \hat{\beta}_g + \hat{\sigma}_g \frac{\lambda(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g)}{\Lambda(\hat{\beta}_g, X_{ig}, \hat{\sigma}_g)} \right] \right\}$$

equation (5) can be estimated by

$$\Delta_f^{Tobit} = [S(\hat{\beta}_m, X_{im}, \hat{\sigma}_m) - S(\hat{\beta}_m, X_{if}, \hat{\sigma}_f)] + [S(\hat{\beta}_m, X_{if}, \hat{\sigma}_f) - S(\hat{\beta}_f, X_{if}, \hat{\sigma}_f)]. \quad (7)$$

Similarly, equation (6) can be estimated by

$$\Delta_m^{Tobit} = [S(\hat{\beta}_m, X_{im}, \hat{\sigma}_m) - S(\hat{\beta}_m, X_{if}, \hat{\sigma}_m)] + [S(\hat{\beta}_m, X_{if}, \hat{\sigma}_m) - S(\hat{\beta}_f, X_{if}, \hat{\sigma}_f)]. \quad (8)$$

If the dependent variable is not censored, i.e. if  $a_1 \rightarrow -\infty$  and  $a_2 \rightarrow \infty$ , both equations reduce to the original Blinder-Oaxaca decomposition described in equation (2).

### 3 Monte Carlo Simulation

To examine the differences between the OLS and the Tobit decomposition, a Monte Carlo simulation with 1,000 replications is applied, departing from the following linear regression model for the two groups  $g = 1, 2$ :

$$y_{ig} = a_g + b_g v_g x_{ig} + w_g e_{ig},$$

with  $i = 1, \dots, N_1, N_1 + 1, \dots, N_1 + N_2$  and  $N_1 = 500, N_2 = 500$ . The explanatory

variable  $x$  and the error term  $e$  represent normally distributed random variables. The model parameters  $a$  and  $b$  are assumed to be equal for the two groups:  $a_1 = a_2 = 1$ ,  $b_1 = b_2 = 5$ . In order to ensure that  $y_1 > y_2$ , the random variables are weighted using the following weights:  $v_1 = 1.5$ ,  $v_2 = 1$ ,  $w_1 = 4$ ,  $w_2 = 1$ .<sup>3</sup>

Figure 1 displays the deviations of the explained and unexplained parts of the OLS and the Tobit decomposition when the dependent variable is censored from below and/or above at a certain percentile. While the gap between the original decomposition and the values estimated by the two models is zero if the dependent variable is uncensored, the decomposition estimates deviate from the original decomposition as soon as the dependent variable is censored. Moreover, the gap widens if the degree of censoring increases. Overall, the results of the Monte Carlo simulation indicate that the Tobit decomposition produces more reliable results than the decomposition based on OLS estimates. However, the differences between the components of the two decomposition methods are not statistically significant.

#### 4 Empirical Illustration: The Gender Wage Gap in Germany

In order to apply the Blinder-Oaxaca decomposition for Tobit-models empirically, we analyze the gender wage gap using data from the German *Socio-Economic Panel* (SOEP) for the year 2004. We estimate the following wage equation separately for males ( $m$ ) and females ( $f$ ):

$$\ln(w_{ig}) = X_{ig}\beta_g + \varepsilon_{ig}, \quad (9)$$

for  $g = m, f$ , where  $w_{ig}$  refers to the gross hourly wage rate of individual  $i$  in group  $g$ . The explanatory variables  $X_i$  include the years of completed schooling, potential labor market experience (calculated as  $Age - Years\ of\ Schooling - 6$ ) and potential labor market experience squared, the number of children, and dummy variables for married individuals, part-time workers, immigrants, and persons residing in East-Germany.<sup>4</sup> We restrict our sample to working individuals aged 16 to 65 and

<sup>3</sup> Note that all parameters of the model were chosen arbitrarily. Alternative simulations were also carried out using different parameters. In addition, different choices of the error term  $\sigma$  were made. The choice of model parameters and error terms, however, did not change our results significantly.

<sup>4</sup> Descriptive statistics are given in the Appendix.

1  
2  
3  
4 eliminated all observations with missing values for at least one of the variables used  
5 in the analysis. This procedure results in a sample of 3,610 observations for men  
6 and 2,465 observations for women.  
7  
8

9  
10 The wage information in the SOEP is uncensored. Therefore, we first apply the  
11 original Blinder-Oaxaca decomposition described in equation (2), using the OLS-  
12 estimates of the regression model (9). In a second step, we generate an artificial  
13 outcome variable by censoring the distribution of gross hourly wages at the lower and  
14 upper 10th percentile. We estimate equation (9) by OLS using the transformed wage  
15 information as dependent variable to show the potential bias in the estimation results  
16 and wage decomposition when ignoring the censoring of the dependent variable. In  
17 a final step, we use the transformed wage variable and estimate equation (9) using  
18 a Tobit model and apply the Tobit-Blinder-Oaxaca decompositions described in  
19 equations (7) and (8). To be able to test the different decomposition results against  
20 each other, we obtain standard errors for the decomposition parts by bootstrapping  
21 with 1000 replications.  
22  
23  
24  
25  
26  
27  
28  
29  
30

31  
32 Table 1 shows the estimates of the OLS and Tobit-models. In all cases, the  
33 estimated coefficients have the expected signs and are statistically significant at  
34 conventional levels. When using the artificially censored outcome variable, the Tobit  
35 estimates perform slightly better than the OLS-estimates in the sense that they are  
36 closer to the respective estimation results when using the original uncensored wage  
37 information.  
38  
39  
40  
41  
42

43 Based on the uncensored wage information, the estimates of the decomposition  
44 analysis reported in column 1 of Table 2 (which do not differ between the OLS  
45 and the various Tobit-decomposition methods) indicate that 67.6% of the wage  
46 differential between men and women is attributable to differences in observable  
47 characteristics.  
48  
49  
50  
51

52 When using the original Blinder-Oaxaca decomposition ( $\Delta^{OLS}$ ), censoring the  
53 dependent variable from below or from both sides of the wage distribution increases  
54 the unexplained part of the wage differential, while the decomposition results do  
55 not change very much when wages are censored just from above. Furthermore,  
56 for left-censoring and censoring from both sides of the wage distribution the Tobit  
57 decomposition methods perform better than the original Blinder-Oaxaca decompo-  
58 sition. In our example, t-tests demonstrate, however, that the differences in the  
59  
60

1  
2  
3  
4 decomposition results between the uncensored and the three censored estimations  
5 are not statistically significant.  
6  
7

## 8 9 5 Conclusion

10  
11  
12 In this paper, a decomposition method for Tobit-models is developed, which allows  
13 the decomposition of the difference in a censored outcome variable between two  
14 groups into a part that is explained by differences in the observed characteristics  
15 and a part attributable to differences in the estimated coefficients of these charac-  
16 teristics. Monte Carlo simulations reveal that this decomposition method produces  
17 more reliable results than applying the conventional Blinder-Oaxaca decomposition  
18 for linear regression models in the case of censored dependent variables. Using data  
19 of the SOEP, we find that the major part of the wage differential between men and  
20 women is attributable to differences in observable characteristics. The results further  
21 show that applying the Tobit decomposition method produces better results than  
22 the original Blinder-Oaxaca decomposition when wages are censored from below  
23 and from both sides of the wage distribution. However, in our example the differ-  
24 ences between the various decomposition methods are not statistically significant,  
25 confirming the results of the Monte Carlo simulation.
