22 **Abstract**
23

24
25
26 Equilibrium geometry parameters of the open shell PbX₂·NO and PbX₂·ON (X=F, Cl, Br, I)
27 complexes have been computed by second-order Z-averaged perturbation theory (ZAPT2)
28 with Stevens-Basch-Krauss-Jasien-Cundari (SBKJC) scalar-relativistic effective core
29 potentials (RECP) and basis sets on all atoms. Equilibrium geometries of both PbX₂·NO and
30 PbX₂·ON bonding isomers conform to C_s symmetry structure with end-on ligand
31 coordination, and are characterized by Pb-N bond length within 266.6 – 271.7 pm range, Pb-
32 O distance of 267.8 – 275.8 pm, Pb-N-O angle within 109.2 – 120.7 deg range, and Pb-O-N
33 angle of 117.1 – 127.8 deg. Anharmonic vibrational spectra of the PbX₂·NO and PbX₂·ON
34 complexes have been calculated by direct correlation-corrected vibrational self-consistent
35 field (CC-VSCF) method enhanced with second-order perturbative correction using potential
36 energy surfaces (PESs) determined at ZAPT2/SBKJC+(d) level in curvilinear (internal)
37 coordinates. Fundamental of ν(Pb-N) stretching mode has been computed at 232.8 to 209.0
38 cm⁻¹ within PbX₂·NO series whereas ν(Pb-O) stretching mode fundamental evaluation in
39 PbX₂·ON series afforded wavenumbers within 183.2 – 150.7 cm⁻¹ range. Blue shift of the
40 ν(N=O) stretching mode wavenumber upon PbX₂·NO complex formation, computed in
41 anharmonic approximation, 15.8 – 14.6 cm⁻¹, correctly reproduces the effect observed in the

1. INTRODUCTION

Blue shift of the intra-ligand stretching mode of σ -donors like CO, NO and N₂, observed in the infrared spectra of fourth row divalent metal halides MX₂ (M=Ca, Cr, Mn, Ni, Cu, Zn) upon MX₂ ·L complex formation [1,2] prompted increased interest in such complexes. Subsequently, similar effect has been detected in the low temperature Ar matrix infrared spectra of the species formed by SnX₂ and PbX₂ halides (X=F, Cl, Br, I) with carbon monoxide, dinitrogen and nitrogen monoxide [3]. Analysis of their infrared spectra led to the conclusion that the structure of SnX₂ ·L and PbX₂ ·L complexes consists of a bent MX₂ moiety with end-on coordinated ligand molecule and the blue shift of intra-ligand stretching mode can be explained in terms of electron density transfer from anti-bonding σ^* orbitals of the ligand to empty d orbitals of the metal [3]. Ab initio study of PbX₂ ·L compounds (L=CO, N₂; X=F, Cl, Br, I) at MP2 level with relativistic effective core potentials (RECP) and basis sets of SBKJC+(d) type afforded description of equilibrium geometry of these species and correctly reproduced, at anharmonic level, shift of $\nu(\text{N}\equiv\text{N})$ and $\nu(\text{C}=\text{O})$ stretching modes to higher energy upon complex formation [4]. Electronic structure of nitrogen monoxide [5] and its complexes with transition metals [6,7] have been extensively studied both experimentally and by computational chemistry methods. Interaction of NO with silver [8], gold [9], and platinum [10] small metal clusters as well as with transition metal clusters embedded in zeolites [11] has also been a subject of considerable interest with relation to heterogeneous catalysis. Variety of binding modes of the NO molecule to metal atoms, resulting in linear N-coordinated, linear O-coordinated, bent N- or O-coordinated, and side-on η^2 coordinated structures have been either observed experimentally [6-11] or investigated by quantum chemistry methods [6,12]. Amongst the computational chemistry methods employed to the elucidation of electronic structure and properties of open-shell systems like nitrogen monoxide complexes with metals and metal ions, perturbational treatment of electron

1
2
3 correlation based on restricted open-shell Hartree-Fock (ROHF) reference wave function has
4
5 been preferred to unrestricted Möller-Plesset (MP) perturbation theory because of better
6
7 convergence properties and lesser sensitivity to spin contamination [13-17]. Characteristics of
8
9 Z-averaged perturbation theory (ZAPT) [13,14], based on ROHF reference wave function,
10
11 appear particularly interesting as the computational demand of the method is comparable to
12
13 that of the closed-shell MP method [14] and it is entirely devoid of spin contamination at
14
15 second order (ZAPT2) [14]. Moreover, since the analytic gradient expressions for second
16
17 order ZAPT theory have been derived [15] and implemented in revised form within
18
19 distributed data interface [16], thus enabling parallel execution of the code on computer
20
21 clusters, the method seems even more attractive for treatment of large open-shell molecular
22
23 systems and detailed PES scans on such molecules. Binding mode of the NO molecule and
24
25 geometry of the complexes have been commonly inferred from the infrared spectra of species
26
27 trapped in low temperature rare gas matrices [3,6] aided with density functional theory (DFT)
28
29 calculations of the harmonic approximation vibrational spectra [6]. Properties of metal cluster
30
31 bound NO have been studied by DFT method [8,10,12] or first-principles based simulation
32
33 packages like VASP [9,11]. In most cases, vibrational spectra computed in the harmonic
34
35 approximation have been used to establish NO binding mode and provide support to
36
37 experimental transition assignments, except for the most recent VASP study on nitric oxide
38
39 adsorption on Pd clusters in mordenite [11], where one-dimensional treatment of NO
40
41 anharmonicity has been applied. The importance of anharmonic treatment of nitric oxide
42
43 complexes becomes evident from the analysis of the latter data [11], where the red shift of
44
45 $\nu(\text{N}=\text{O})$ stretching mode of Pd cluster bound NO is contrasted with the blue shift of this mode
46
47 in mordenite supported Pd clusters.

48
49 Vibrational self-consistent field (VSCF) theory [18-22], an analog of self-consistent field
50
51 method in electronic structure theory, provides a route to computation of anharmonic

59
60

1
2
3 approximation vibrational spectrum by taking into account intrinsic anharmonicity related to
4 vibrational motion along single normal mode in the mean field of the remaining modes, as
5 well as that originating in inter-mode coupling. PES points required by the direct VSCF
6 method are computed on a rectangular grid derived from normal mode displacements in
7 rectilinear [23,24] or curvilinear (internal) [25] coordinates along single modes and mode
8 pairs (and possibly mode triples) by electronic structure method of choice. It has been shown
9 that VSCF method based on PES grid derived from normal mode displacements in curvilinear
10 coordinates provides better description of low energy large amplitude vibrations [25] as
11 compared to that employing grid deduced from rectilinear coordinates [23,24]. Correlation
12 corrected extensions of VSCF method, termed CC-VSCF, based on either virtual
13 configuration interaction (VCI) including singly and doubly excited states [23,26] or second-
14 order non-degenerate [23,26] and degenerate [27,28] perturbation theory account for inter-
15 mode correlation effects. CC-VSCF method has been successfully applied to weakly bound
16 species like rare gas (Rg) hydrogen fluoride HRgF complexes [29], HXeI [30], HXeOH [31],
17 as well as to $\text{PbX}_2 \cdots \text{L}$ complexes ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$; $\text{L} = \text{CO}, \text{N}_2$) [4]. Noticeably, VSCF method
18 provided correct explanation of the anomalous isotope effect in the spectrum of HXeOH [31],
19 and a blue shift of $\nu(\text{N}\equiv\text{N})$ and $\nu(\text{C}=\text{O})$ stretching modes upon $\text{PbX}_2 \cdots \text{L}$ complex formation
20 [4]. Having this in mind, one can anticipate that anharmonic level description of open-shell
21 $\text{PbX}_2 \cdots \text{NO}$ and $\text{PbX}_2 \cdots \text{ON}$ species ($\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$) vibrational spectra by correlation corrected
22 VSCF method seems feasible.

isomer species. Influence of mode-mode coupling strength on anharmonic corrections is also discussed.

2. METHODS

All computations of equilibrium geometry, harmonic approximation vibrational spectra, CC-VSCF fundamentals and overtone transitions were done within electronic structure suite of programs GAMESS [32]. Equilibrium geometry parameters of $\text{PbX}_2 \cdot \text{NO}$ and $\text{PbX}_2 \cdot \text{ON}$ ($\text{X}=\text{F}, \text{Cl}, \text{Br}, \text{I}$) complexes were evaluated under C_s symmetry constraints using parallel implementation [16] of second-order Z-averaged perturbation theory (ZAPT2) [13-15] and Stevens-Basch-Krauss-Jasien-Cundari (SBKJC) scalar-relativistic effective core potentials (RECP) and valence basis sets on all atoms [33-36]. Replacement of all-electron basis sets by effective core potentials does not lead to significant loss of accuracy even in case of 2-nd and 3-rd row elements [37]. SBKJC basis set was augmented with single d-type polarization and single L-type diffuse functions, denoted as SBKJC+(d). Harmonic approximation vibrational spectra of the complexes were computed from Hessians evaluated by numerical differentiation of analytic ZAPT2 gradients. Two-mode representation of the VSCF system potential [23,26,27], including single mode (diagonal) $V_i^{\text{diag}}(Q_i)$ and mode-mode coupling $V_{ij}^{\text{coup}}(Q_i, Q_j)$ terms was assumed, based on adequate description of $\text{PbX}_2 \cdot \text{L}$ anharmonicity [4] by such truncated expression:

$$V(Q_1, \dots, Q_N) = \sum_j V_j^{\text{diag}}(Q_j) + \sum_i \sum_{j>i} V_{ij}^{\text{coup}}(Q_i, Q_j)$$

where N is the number of normal modes and Q_i and Q_j are i -th and j -th normal coordinates.

Potential energy and dipole moment surfaces were computed at ZAPT2/SBKJC+(d) level on 16 point grid (diagonal potentials) and 16x16 point square grid (coupling potentials) derived from normal mode displacements in curvilinear (internal) coordinates within $[-4\omega_i^{-0.5}, +4\omega_i^{-0.5}]$

0.5] range (where ω_i is the frequency of i-th normal mode). Direct CC-VSCF method required calculation of 9360 PES points for each species. Intensities of fundamental transitions were evaluated using ZAPT2 dipole moment surfaces and VSCF wavefunctions of the corresponding states,

$$I_i = \frac{8\pi^3 N_a}{3hc} \omega_i \left| \langle \Psi_i^{(0)}(Q_i) | \bar{\mu}(Q_i) | \Psi_i^{(m)}(Q_i) \rangle \right|^2$$

where $\psi_i^{(0)}$ and $\psi_i^{(m)}$ denote VSCF wavefunctions of the ground and the m-th excited vibrational states of i-th normal mode, ω_i is the CC-VSCF vibrational frequency of this mode, and the remaining symbols have their regular meaning [26].

3. RESULTS AND DISCUSSION

3.1. Equilibrium geometry

It seems worth noting that equilibrium bond length of free NO computed at ZAPT2/SBKJC+(d) level (Table 1) is longer than experimental bond distance of 115.1 pm [38] by 4.1 pm, and longer by 3.4 pm with relation to that calculated by ZAPT2 method using triple-zeta quality basis set TZ2P [14]. Although overestimation of $r(\text{N}=\text{O})$ distance appears significant, it seems of secondary importance in computation aimed at anharmonic level description of vibrational transitions in $\text{PbX}_2 \cdot \text{NO}$ and $\text{PbX}_2 \cdot \text{ON}$ complexes, including blue shift of $\nu(\text{N}=\text{O})$ stretching mode upon complex formation. On the other hand, equilibrium bond distances and angles of lead halides evaluated under C_{2v} symmetry by MP2 method in the same basis set (Table 1) overestimate experimental gas phase geometry parameters derived from electron diffraction [39] to a less significant extent with the exception of PbF_2 , where $r(\text{Pb}-\text{F})$ distance is longer than experimental r_g value by 1.4 pm (Table 1). Nonetheless,

1
2
3 the difference is almost negligible, even when $r_e < r_g$ relationship is taken into account [39]. A
4
5 noticeable shortening of $r(\text{N}=\text{O})$ distance upon $\text{PbX}_2 \cdots \text{NO}$ complex formation (0.2 – 0.3 pm)
6
7 occurs in concord with halide dependent lengthening of $r(\text{Pb}-\text{X})$ distance, amounting to 1.4
8
9 pm ($\text{PbF}_2 \cdots \text{NO}$) – 2.3 pm ($\text{PbI}_2 \cdots \text{NO}$) (Table 1). Opposite change or no change in $r(\text{N}=\text{O})$ bond
10
11 length is observed on formation of $\text{PbX}_2 \cdots \text{ON}$ species in accord with less pronounced increase
12
13 in $r(\text{Pb}-\text{X})$ distance (0.7 – 1.0 pm) on going from fluoride to iodide. Equilibrium geometry of
14
15 $\text{PbX}_2 \cdots \text{NO}$ species (Figure 1), characterized by $r(\text{Pb}-\text{N})$ bond distance within 266.6 – 271.7
16
17 pm, and $(\text{Pb}-\text{N}-\text{O})$ angle of 109.2 – 120.7 deg, differs considerably from that of $\text{PbX}_2 \cdots \text{N}_2$ [4]
18
19 complex by much shorter Pb-N bond length and less obtuse Pb-L-L angle (where L-L
20
21 represents ligand molecule). Moreover, computed $(\text{Pb}-\text{N}-\text{O})$ angle in $\text{PbX}_2 \cdots \text{NO}$ series nears
22
23 that characteristic of N-coordinated NO molecule with sp^2 hybridized nitrogen atom in
24
25 transition metal complexes [12]. Isomer complex molecule, $\text{PbX}_2 \cdots \text{ON}$ (Figure 2) shows
26
27 slightly longer Pb-O bond length (Table 1), varying between 267.8 and 275.8 pm, and more
28
29 obtuse $(\text{Pb}-\text{O}-\text{N})$ angle, as compared to $\text{PbX}_2 \cdots \text{NO}$ species. Despite remote similarity, it can be
30
31 noted that the longest Pb-O bond distances of $\text{Pb}_4(\text{OH})_4^{4+}$ (252 pm) [45] and $\text{Pb}_6\text{O}(\text{OH})_6^{4+}$
32
33 (267.7 pm) [46] ions, computed at MP2 level in scalar relativistic ECP basis [45,46], are very
34
35 close to those of $\text{PbX}_2 \cdots \text{ON}$ series. One can also note that lengthening of $r(\text{Pb}-\text{L})$ distance and
36
37 increase in $(\text{Pb}-\text{L}-\text{L})$ angle in both $\text{PbX}_2 \cdots \text{NO}$ and $\text{PbX}_2 \cdots \text{ON}$ isomers follows the order of
38
39 decreasing electronegativity of halogen atoms and, in consequence, decreasing positive
40
41 charge on Pb atom.
42
43
44
45
46
47
48
49

50 51 3.2. Anharmonic spectra of $\text{PbF}_2 \cdots \text{NO}$ and $\text{PbF}_2 \cdots \text{ON}$ complexes

52
53
54
55 Harmonic wavenumber of $\nu(\text{N}=\text{O})$ mode computed at ZAPT2/SBKJC+(d) level (1890.1 cm^{-1} ;
56
57 Table 2) compares favorably against that computed by the same method in triple-zeta valence
58
59 basis set, TZ2P (1895.8 cm^{-1}) [14]. VSCF computed fundamental of this mode (1869.1 cm^{-1}),
60

1
2
3 including intrinsic (diagonal) anharmonicity, appears reasonably close to the transition
4
5 wavenumber observed in the Ar matrix spectrum of NO (1875.0 cm^{-1}) [3], showing deviation
6
7 typical of VSCF method for stretching modes [23-27]. Since there is no contribution to
8
9 anharmonic correction from mean field effect or inter-mode correlation in the case of
10
11 molecule with single vibrational mode, the aforementioned wavenumber of $\nu(\text{N}=\text{O})$
12
13 fundamental will be used to evaluate anharmonic shift of $\nu(\text{N}=\text{O})$ mode upon complex
14
15 formation. VSCF computed anharmonic spectra of $\text{PbF}_2\cdot\text{NO}$ and $\text{PbF}_2\cdot\text{ON}$ complexes (Table
16
17 2) provide fundamentals corrected for intrinsic (diagonal) anharmonicity, mean field and
18
19 mode-mode coupling (VSCF), and mode correlation at degenerate second order
20
21 perturbational (DPT2-VSCF) level. For the reason stated above, $\nu(\text{N}=\text{O})$ fundamental of the
22
23 coordinated NO, corrected for intrinsic anharmonicity, will be used to assess wavenumber
24
25 shift due to complex formation. Fundamentals of PbF_2 , computed at MP2/SBKJC+(d) level
26
27 (Table 2), show negligible deviation from low temperature Ne matrix spectrum [42] whereas
28
29 those of $\nu_s(\text{Pb-F})$ and $\nu_a(\text{Pb-F})$ modes in $\text{PbF}_2\cdot\text{NO}$ complex overestimate transition
30
31 wavenumbers measured in low temperature Ar matrix [3] by $\sim 10\text{ cm}^{-1}$, partly due to matrix
32
33 polarizability effects [39]. It seems interesting to note that the harmonic approximation
34
35 provides qualitatively incorrect description of $\nu(\text{N}=\text{O})$ mode shift on $\text{PbF}_2\cdot\text{NO}$ complex
36
37 formation (-11.7 cm^{-1}) whereas the wavenumber difference of the respective fundamentals
38
39 ($+15.8\text{ cm}^{-1}$) nears that deduced from experiment ($+16.4\text{ cm}^{-1}$) [3]. Although wavenumber
40
41 shifts of $\nu_s(\text{Pb-F})$ and $\nu_a(\text{Pb-F})$ fundamentals on going from PbF_2 to $\text{PbF}_2\cdot\text{NO}$ are lower than
42
43 those estimated in the harmonic approximation, they are still larger than shifts assessed
44
45 experimentally [3]. Wavenumber of high intensity $\nu(\text{Pb-N})$ fundamental at 232.8 cm^{-1} is 10
46
47 cm^{-1} lower than its harmonic counterpart, with majority of anharmonic correction coming
48
49 from intrinsic anharmonicity and mean field / mode coupling effects. Same pattern of
50
51 anharmonic corrections can be observed for all $\text{PbF}_2\cdot\text{NO}$ fundamentals (Table 2), whereas
52
53
54
55
56
57
58
59
60

contribution to anharmonicity resulting from mode correlation appears significant only in the case of $\nu_a(\text{Pb-F})$ mode, leading to 0.8 cm^{-1} difference between VSCF and DPT2-VSCF wavenumbers. Analysis of the mode-mode coupling pattern of $\text{PbF}_2 \cdot \text{NO}$ vibrational modes, represented as a two-dimensional mapping of $V_{i,j}^{\text{coup}}(Q_i, Q_j)$ mode coupling potential (Figure 3) on $N \times N$ PES grid,

$$P(Q_i, Q_j) = \left\{ \begin{array}{l} N \sum_{p=1}^N |V(n_{ip})| \text{ if } i = j \\ \sum_{p=1}^N \sum_{q=1}^N |V(n_{ip}, n_{jq})| \text{ otherwise} \end{array} \right\}$$

where n_{ip} and n_{jq} are grid points and N is the number of grid points ($N=16$), reveals that inter-mode coupling contribution to VSCF anharmonic correction seems substantial for $\nu_s(\text{Pb-F})$ and $\nu_a(\text{Pb-F})$, $\nu(\text{Pb-N})$ and $\rho_w(\text{PbF}_2)$, $\rho_w(\text{PbF}_2)$ and $\rho_t(\text{PbF}_2)$ mode pairs. Since no experimental evidence of $\text{PbX}_2 \cdot \text{ON}$ complexes has been reported to date, their anharmonic spectra can be compared against those of $\text{PbX}_2 \cdot \text{NO}$ isomer or structurally similar lead(II) compounds. Fundamental transitions of $\text{PbF}_2 \cdot \text{ON}$ isomer (Table 2) can be viewed as characteristics of O-coordinated NO molecule, as evidenced by 33.4 cm^{-1} red shift of $\nu(\text{N=O})$ stretching mode upon complex formation and less pronounced shifts of $\nu_s(\text{Pb-F})$ and $\nu_a(\text{Pb-F})$ fundamentals on going from PbF_2 to $\text{PbF}_2 \cdot \text{ON}$. Wavenumber of $\nu(\text{Pb-O})$ fundamental, computed at 183.2 cm^{-1} , shows significant anharmonic correction due to intrinsic anharmonicity and mean field / mode coupling and appears remarkably close to the lowest energy $\nu(\text{Pb-O})$ stretching mode of $\text{Pb}_6\text{O}(\text{OH})_6^{4+}$ ion (179 cm^{-1}) [46], evaluated in the harmonic approximation at MP2/ECP level. Anharmonic corrections of $\text{PbF}_2 \cdot \text{ON}$ modes lack significant contribution from mode correlation with the exception of $\rho_t(\text{PbF}_2)$ twisting mode, where DPT2-VSCF fundamental appears 2.8 cm^{-1} above its VSCF analog. Mapping of $\text{PbF}_2 \cdot \text{ON}$ coupling potentials (Figure 4), evaluated at ZAPT2/SBKJC+(d) level, indicates that $\nu_s(\text{Pb-F})$ and $\nu_a(\text{Pb-F})$, $\nu(\text{Pb-O})$ and $\rho_w(\text{PbF}_2)$, $\rho_w(\text{PbF}_2)$ and $\rho_t(\text{PbF}_2)$ mode pairs are strongly

1
2
3 coupled, which leads in consequence to sizable VSCF anharmonic corrections of the
4
5
6 respective fundamentals. Similarity of mode coupling patterns of $\text{PbF}_2\cdots\text{NO}$ and $\text{PbF}_2\cdots\text{ON}$
7
8 implies that interaction between mode pairs does not depend substantially on NO
9
10 coordination mode, but rather involves fundamentals originating in analogous normal mode
11
12 displacements, like $\rho_w(\text{PbF}_2)$ and $\rho_t(\text{PbF}_2)$ mode pair of both isomers. Same characteristics of
13
14 the two-dimensional mapping of mode coupling potential pertain to the remaining members
15
16 of $\text{PbX}_2\cdots\text{NO}$ and $\text{PbX}_2\cdots\text{ON}$ series, so that their coupling patterns are not reported here for the
17
18 sake of brevity. VSCF computation predicts the most intense overtone and combination
19
20 transitions of $\text{PbF}_2\cdots\text{NO}$ and $\text{PbF}_2\cdots\text{ON}$ complexes (Table 2a) to originate in $\nu_s(\text{Pb-F})$, $\nu_a(\text{Pb-F})$,
21
22 $\nu(\text{Pb-N})$, $\nu(\text{Pb-O})$, $\rho_w(\text{PbF}_2)$, and $\tau(\text{N=O})$ modes, which display high intensity fundamentals
23
24 and are mutually coupled to an appreciable extent (Figures 2 and 3). Anharmonic corrections
25
26 of overtones and combination transitions (Table 2a) almost exclusively stem from diagonal
27
28 anharmonicity and mean field / coupling effects whereas contribution of inter-mode
29
30 correlation appears nearly negligible.

40

41 3.3. Anharmonic spectra of $\text{PbCl}_2\cdots\text{NO}$ and $\text{PbCl}_2\cdots\text{ON}$ complexes

42
43
44 Fundamentals of PbCl_2 , computed at MP2/SBKJC+(d) level, are reported in Table 3 as a
45
46 reference enabling evaluation of wavenumber shift of $\nu_s(\text{Pb-Cl})$ and $\nu_a(\text{Pb-Cl})$ modes resulting
47
48 from complex formation. Their wavenumbers overestimate experimental Ar matrix spectrum
49
50 [3] by 12 – 29.7 cm^{-1} due to matrix polarizability effects as well as inaccuracy of the VSCF
51
52 method itself. Vibrational transitions of $\text{PbCl}_2\cdots\text{NO}$ and $\text{PbCl}_2\cdots\text{ON}$ isomers (Table 3) are
53
54 weakly anharmonic with the exception of $\nu(\text{Pb-N})$, $\nu(\text{Pb-O})$, $\rho_w(\text{PbCl}_2)$, $\rho_t(\text{PbCl}_2)$, and
55
56 $\tau(\text{N=O})$ modes, whose DPT2-VSCF fundamentals are 4 – 10 cm^{-1} lower in energy than their
57
58 harmonic equivalents. Anharmonic corrections of $\text{PbCl}_2\cdots\text{NO}$ and $\text{PbCl}_2\cdots\text{ON}$ modes originate
59
60

1
2
3 for the most part in diagonal anharmonicity and mean field / coupling effects with minor
4 contribution from mode-mode correlation. Wavenumber shift of $\nu(\text{N}=\text{O})$ fundamental on
5
6
7
8
9
10
11 amounts to 14.2 cm^{-1} , in accord with reduced σ donation from NO molecule to less positively
12 charged lead ion [3]. Similar effect can be observed in the VSCF spectrum of $\text{PbCl}_2 \cdot \text{ON}$
13
14
15 complex, where O-coordination of NO molecule generates oppositely signed shift of $\nu(\text{N}=\text{O})$
16
17
18 fundamental by -30.7 cm^{-1} as compared to -33.4 cm^{-1} in $\text{PbF}_2 \cdot \text{ON}$ (Table 6). For the same
19
20
21 reason the change in energy of $\nu_s(\text{Pb}-\text{Cl})$ and $\nu_a(\text{Pb}-\text{Cl})$ fundamentals on going from PbCl_2 to
22

59
60
 $\text{PbCl}_2 \cdot \text{NO}$, amounting to -8.9 cm^{-1} and -8.6 cm^{-1} , respectively, is much smaller than that
computed for the fluoride analog. The same effect is also responsible for the decreased
wavenumber shifts of $\nu_s(\text{Pb}-\text{Cl})$ and $\nu_a(\text{Pb}-\text{Cl})$ fundamentals upon $\text{PbCl}_2 \cdot \text{ON}$ complex
formation. Discernible diminution of the wavenumbers of $\nu(\text{Pb}-\text{N})$ and $\nu(\text{Pb}-\text{O})$ fundamentals
in $\text{PbCl}_2 \cdot \text{NO}$ and $\text{PbCl}_2 \cdot \text{ON}$ complexes with relation to fluoride analogs (Table 3) can be
attributed to the weakening of Pb-N and Pb-O bonds on fluoride to chloride substitution
caused by diminished σ donation from NO molecule, mentioned above. Anharmonic
corrections of $\tau(\text{N}=\text{O})$ torsional mode in $\text{PbCl}_2 \cdot \text{NO}$ and $\text{PbCl}_2 \cdot \text{ON}$ isomers stem for the most
part from mean field / mode coupling effects and appear coordination mode dependent,
leading to 18.6 cm^{-1} difference between harmonic and VSCF wavenumber of this mode in the
case of O-coordinated NO molecule.

3.4. Anharmonic spectra of $\text{PbBr}_2 \cdot \text{NO}$ and $\text{PbBr}_2 \cdot \text{ON}$ complexes

The assignment of $\nu_s(\text{Pb}-\text{Br})$ and $\nu_a(\text{Pb}-\text{Br})$ stretching modes in the gas phase spectrum of
 PbBr_2 , placing antisymmetric mode at higher energy than symmetric one [43] contradicts the
order observed in other PbX_2 halides [3] and also that of VSCF computed fundamentals [4]

(Table 4). Therefore, a reversal of experimental assignment placing $\nu_s(\text{Pb-Br})$ mode higher in energy than $\nu_a(\text{Pb-Br})$ would be consistent with VSCF calculation and VSCF computed intensity pattern of these two fundamentals (Table 4). Fundamentals of $\text{PbBr}_2\cdots\text{NO}$ and $\text{PbBr}_2\cdots\text{ON}$ isomers are weakly anharmonic with no significant contribution to anharmonicity from correlation correction. Fundamental of $\nu(\text{N=O})$ mode shows blue shift of 14.6 cm^{-1} on $\text{PbBr}_2\cdots\text{NO}$ complex formation whereas creation of O-coordinated $\text{PbBr}_2\cdots\text{ON}$ species results in -28.0 cm^{-1} red shift of this mode. It can also be noted (Table 4) that significant coupling of $\nu(\text{Pb-N})$ mode of $\text{PbBr}_2\cdots\text{NO}$ to $\nu_s(\text{Pb-Br})$ symmetric stretch results in sizable increase of $\nu_s(\text{Pb-Br})$ fundamental intensity, making it almost indistinguishable from that of $\nu_a(\text{Pb-Br})$ antisymmetric stretching fundamental. Wavenumbers of $\nu_s(\text{Pb-Br})$ and $\nu_a(\text{Pb-Br})$ fundamentals in $\text{PbBr}_2\cdots\text{NO}$ are lower than those of the analogous modes in PbBr_2 by -3.0 and -6.3 cm^{-1} , respectively, while formation of $\text{PbBr}_2\cdots\text{ON}$ complex shifts both modes to lower energy by -3.1 cm^{-1} . A decrease in the energy of $\nu(\text{Pb-N})$ and $\nu(\text{Pb-O})$ fundamentals in $\text{PbBr}_2\cdots\text{NO}$ and $\text{PbBr}_2\cdots\text{ON}$ isomers with relation to those of the fluoride and chloride analogs follows the order of decreasing positive charge on lead(II) ion and, in consequence, decreasing Pb-N and Pb-O bond strengths. Interestingly, sensitivity of the vibrational modes involving PbBr_2 moiety as a whole, $\rho_w(\text{PbBr}_2)$ and $\rho_t(\text{PbBr}_2)$, to the NO coordination mode can be viewed as a demonstration of difference in Pb-N and Pb-O bond strengths.

3.5. Anharmonic spectrum of $\text{PbI}_2\cdots\text{ON}$ complex

Fundamental transitions of PbI_2 computed by DPT2-VSCF method (Table 5) are weakly anharmonic and their wavenumbers do not differ appreciably from Ar and Kr matrix spectra extrapolated to zero matrix polarizability [39]. **Since the VSCF procedure did not converge in the case of $\text{PbI}_2\cdots\text{NO}$ complex, only anharmonic spectrum of $\text{PbI}_2\cdots\text{ON}$ species is reported in**

Table 5. The red shift of $\nu(\text{N}=\text{O})$ fundamental on $\text{PbI}_2 \cdot \text{ON}$ complex formation (-30.4 cm^{-1}) exceeds that calculated in the harmonic approximation (-25.5 cm^{-1}), revealing the importance of anharmonic correction in the case of $\nu(\text{N}=\text{O})$ mode. The wavenumber of $\nu(\text{Pb}-\text{O})$ fundamental (150.7 cm^{-1}) differs from its harmonic counterpart by 8.6 cm^{-1} due to nearly equal diagonal and mean field / mode coupling contributions to anharmonic correction. The energy of that mode is the lowest in $\text{PbX}_2 \cdot \text{ON}$ series, in agreement with the trend observed for other members of the series. VSCF computed shifts of $\nu_s(\text{Pb}-\text{I})$ and $\nu_a(\text{Pb}-\text{I})$ fundamentals upon complex formation, -1.4 and -2.1 cm^{-1} , respectively, are significantly lower than those evaluated for the other $\text{PbX}_2 \cdot \text{ON}$ species, due to dramatically weakened σ -donation from the ligand. In line with the characteristics of $\text{PbF}_2 \cdot \text{ON}$ and $\text{PbCl}_2 \cdot \text{ON}$ anharmonic spectra, the lowest energy $\tau(\text{N}=\text{O})$ torsional mode fundamental shows exceptionally large anharmonic correction, stemming mostly from intrinsic anharmonicity with smaller contributions arising from VSCF and mode correlation effects.

4. CONCLUSIONS

Equilibrium geometry parameters of the open-shell $\text{PbX}_2 \cdot \text{NO}$ and $\text{PbX}_2 \cdot \text{ON}$ species, evaluated at ZAPT2/SBKJC+(d) level, depict both isomers as NO molecule end-on coordinated to PbX_2 halide with NO molecular axis nearly parallel to the PbX_2 plane (Figures 1 and 2). Computation of the anharmonic approximation vibrational spectra of $\text{PbX}_2 \cdot \text{NO}$ ($\text{X}=\text{F}, \text{Cl}, \text{Br}$) and $\text{PbX}_2 \cdot \text{ON}$ ($\text{X}=\text{F}, \text{Cl}, \text{Br}, \text{I}$) complexes by DPT2-VSCF method at the same level of theory afforded satisfactory description of the experimental Ar matrix spectrum of $\text{PbF}_2 \cdot \text{NO}$ species [3] and provided sensibly consistent predictions of the spectra of the remaining compounds. Harmonic approximation based wavenumber shift of the $\nu(\text{N}=\text{O})$ mode upon $\text{PbX}_2 \cdot \text{NO}$ complex formation (Table 6) appears qualitatively incorrect as being oppositely signed to the experimental one, whereas that computed from VSCF fundamentals

1
2
3 agrees with experiment within a fraction of a wavenumber ($\text{PbF}_2 \cdot \text{NO}$). VSCF computed
4
5 wavenumbers of $\nu(\text{Pb-N})$ and $\nu(\text{Pb-O})$ stretching mode fundamentals of the respective
6
7 bonding isomers decrease in accord with the decreasing ionic character of Pb-X bond,
8
9 following the order: $\text{F} > \text{Cl} > \text{Br} > \text{I}$. Energy changes of $\nu_s(\text{Pb-X})$ and $\nu_a(\text{Pb-X})$ fundamentals
10
11 on going from PbX_2 to $\text{PbX}_2 \cdot \text{NO}$ and $\text{PbX}_2 \cdot \text{ON}$ species conform to the same trend (Table 6),
12
13 with VSCF computed values being closer to the experiment. Despite substantial
14
15 overestimation of $r(\text{N=O})$ bond length at ZAPT2/SBKJC+(d) level, the fundamental of
16
17 $\nu(\text{N=O})$ mode, corrected for intrinsic anharmonicity, provided satisfactory description of
18
19 coordination mode dependent changes in $\nu(\text{N=O})$ mode wavenumber upon complex
20
21 formation.
