Abstract

Background: This survey aims to describe current practice in ambulatory care among pediatric anesthesiologists in France.

Methods: Members of the French-speaking Pediatric Anesthesiologists Association (ADARPEF) were sent a questionnaire examining the proportion of pediatric ambulatory anesthesia practiced by each responder, the level of adherence to pediatric ambulatory anesthesia guidelines, and responder consensus in decision making when faced with common case scenarios in pediatric ambulatory anesthesia. For the latter, consensus was defined as a >80 % opinion.

Results: 145 pediatric anesthesiologists replied (43%). Ambulatory anesthesia appears underused in France. Recent French pediatric ambulatory anesthesia guidelines are being applied. Post operative pain is poorly managed. The choice of scheduling children for ambulatory anesthesia appears to be more heavily influenced by practitioners' subjective evaluation than evidence from the literature.

Conclusion: A better commitment for ambulatory care must be found amongst anesthesiologists. Further studies are required to improve coherence, safety and efficiency of children selection for ambulatory anesthesia.

Key-words: children, pediatric anesthesia, outpatient procedures, ambulatory

Introduction

Ambulatory pediatric anesthesia has substantial benefits over inpatient anesthesia, provided care is high quality and patient selection is appropriate. In 2008, experts from National Council of Pediatric Surgery (Conseil national de Chirurgie de l'Enfant : CNCE) and from the French-speaking Pediatric Anesthesiologists Association (Association des Anesthésistes Réanimateurs Pédiatriques d'Expression Française : ADARPEF) conjointly examined updated data on ambulatory pediatric surgery. Quality and safety guidelines regarding good anesthetic practice in patients aged < 18 years scheduled for ambulatory procedures were drafted from the data. The guideline recommendations related to issues around having dedicated ambulatory care units, specific medical skills, patient selection and peri-operative management. These guidelines were field tested in a limited number of hospitals, approved by the CNCE and ADARPEF, officially adopted by the French Ministry of Health, and published electronically on both institutions' websites in May 2009 (1; 2). The guidelines defined ambulatory anesthesia as "every mode of planned anesthesia given by an anesthesiologist during a stay < 1 day's duration".

Six months after e-publication, the ADARPEF performed a survey aiming to examine pediatric ambulatory anesthesia practice in France. The survey had two related aims: (i) determine the level of adherence to the above mentioned pediatric ambulatory anesthesia guidelines (ii) gather further information about what pediatric anesthesiologists thought were suitable cases for ambulatory anesthesia by eliciting clinician responses to theoretical case scenarios in pediatric ambulatory anesthesia.

Materials and Methods

In November 2009, 341 ADARPEF members, all of whom were practicing in France, were e-mailed a questionnaire that remained available on the ADARPEF web-site for a further month. Non-responding members were sent a reminder 15 days later.

The questionnaire was in 3 sections. The 1st (table 1) inquired the practitioners' seniority, the proportion of their anesthesia activity that was pediatric, and, for children aged < 18 years, their

1
2 annual number and percentage of cases that were performed in ambulatory mode. The type of
3
4 medical structure was defined (teaching/university, public, private, etc), as was the level of pediatric
5
6 activity, and the presence or absence of dedicated pediatric surgery and day care units.
7

8
9 The 2nd section (table 2) asked the lowest accepted age for ambulatory care, most commonly
10
11 performed ambulatory procedures, and descriptions of peri-anesthetic management.
12

13
14 The 3rd section (table 3) presented responders with 24 different pediatric anesthesia case-scenarios
15
16 drawn up by the ADARPEF Scientific Committee. Scenarios presented common ambulatory
17
18 procedures in children, with or without common or clinically important symptoms, illnesses, or pre-
19
20 existing co-morbidities. Symptoms and co-morbidities included asthma, diabetes mellitus,
21
22 malignant hyperthermia susceptibility, morbid obesity, obstructive sleep apnea (OSA), sickle-cell
23
24 disease, fever, signs of upper respiratory tract infection. Responders were asked for a yes/no
25
26 response as to suitability for ambulatory care for each scenario. An 80% majority opinion was
27
28 chosen as a consensus. A dedicated pediatric anesthesiologist was defined as one whose clinical
29
30 practice included more than 50% of patients < 18 years of age.
31
32
33

34 35 **Subjects studied**

36
37 Completed questionnaires were descriptively analyzed. Correlation between guidelines
38
39 recommendations, responders' medical structures and peri-operative management was assessed.
40
41 Responder consensus to proceed with ambulatory care for patients according to clinical case
42
43 scenarios was analyzed.
44
45

46 47 **Results** (tables 1, 2, 3)

48
49 Only 145 of 341 members (43%) replied over the one month period. All were included in analysis.

50
51 Only 42 of a total of 3480 questions were left unanswered (1%).
52

53
54 Almost $\frac{3}{4}$ of responders (72%) were experienced pediatric anesthesiologists according to the study
55
56 definition. Almost $\frac{1}{2}$ (47%) practiced exclusively in pediatrics, predominantly in
57
58 university/teaching hospitals. Ambulatory anesthesia represented around $\frac{1}{3}$ of overall clinical
59
60 practice and commonly involved imaging, endoscopic, orthopedic and ENT procedures. Over 90%

1
2 of responders reported practicing in structures with dedicated pediatric inpatient, pediatric surgery,
3
4 and ambulatory care units as recommended by the guidelines.
5

6
7 Almost 60% of responders worked in units that hold regular meetings to discuss the pertinence of
8
9 choices made between ambulatory and inpatient care in a selection of patients. This is
10
11 recommended by the guidelines. These meetings assess whether the type of care chosen
12
13 (ambulatory or hospitalization) was adapted to each patient given age, pathology and type of
14
15 procedure. The aim is to improve future admission selection. Further, in accordance with the
16
17 guidelines, 6 months was the predominant lowest acceptable age for ambulatory care in 43% of
18
19 responders, and the majority of parents were given documentation describing the peri-operative
20
21 period. A minority of responders (25%) prescribed systematic anticipatory analgesia, and 1/3
22
23 prescribed rescue analgesia.
24
25
26

27
28 Only 42% of case scenarios resulted in consensus for proceeding with or deciding against
29
30 ambulatory care. One third resulted in 40 to 60% agreement - a strong lack of consensus.
31
32

33 Discussion

34
35 The results must be discussed in the light of the survey's limits: (i) most responders work
36
37 predominantly in teaching/university hospitals, unrepresentative of the French ambulatory pediatric
38
39 anesthesia as a whole, which is mainly ENT procedures in private clinics; (ii) the responder rate is
40
41 low; this may be due partly to indifference for ambulatory mode, partly to the short survey duration,
42
43 and partly to dedicated member practice in fields unconcerned by ambulatory pediatric anesthesia
44
45 (Neurosurgery, Cardiac Surgery, Critical Care, Pain Medicine); (iii) case scenario descriptions were
46
47 limited to yes/no responses which facilitated analysis but excluded many variables; (iv) socio-
48
49 familial or discharge criteria were not explored. Despite these weaknesses, the results described in
50
51 this study probably do reflect pediatric anesthesiologists' practice in France.
52
53
54

55
56 Despite the advantages of ambulatory anesthesia for children, ambulatory care is underutilized in
57
58 France. The overall ambulatory rate is lower than the $\geq 50\%$ reported from many other countries (3-
59
60 5). Children are generally well suited to ambulatory anesthesia, given the disturbance that

1
2 hospitalization represents to them, and the relatively benign nature of many pediatric surgical
3
4 procedures (6). With well managed pediatric ambulatory care, demonstrating expertise and building
5
6 patient and parent confidence, more complex patients can also be managed in an ambulatory setting.
7
8 Consequently, ambulatory care should be the preferred choice in children, and physicians should
9
10 have to justify overnight hospitalization.
11
12

13
14 The main findings of the study were that most responders respect CNCE/ADARPEF guideline
15
16 recommendations in terms of care structures, parent information and review of ambulatory care.
17
18 Broadest agreement for a minimum age of pediatric ambulatory anesthesia also corresponds with
19
20 guidelines. Low prescription rates of discharge analgesics are a major concern, previously reported
21
22 elsewhere (4; 7). Subsequent fear of inadequate analgesia felt by children or parents may even
23
24 reduce acceptance of ambulatory care.
25
26

27
28 Compared to other similar studies, the consensus rates to case scenarios asking whether patients
29
30 were suitable for ambulatory care were low, although higher than in a similar Canadian study of 64
31
32 responders (8). One reason may be that the definition of an 80% majority opinion as consensus was
33
34 more severe than the 65% used by the ASA, the 70% used in the Canadian study, and the 75% used
35
36 in other surveys (9). To give an informed yes or no answer as to the appropriateness of ambulatory
37
38 care, responders needed to be knowledgeable about the anesthetic complications of the pathologies
39
40 described in case scenarios, and to allow for patient age and type of procedure. They also needed to
41
42 know whether complications were likely to be immediate or delayed, the latter invoking caution.
43
44

45
46 Case scenarios responses indicate that practitioners are more likely to decide upon ambulatory care
47
48 subjectively rather than using evidence in the literature. For instance, the fact that diabetes mellitus
49
50 is not a predictor of increased morbidity in pediatric anesthesia, provided that peri-operative fasting
51
52 is reduced (10; 11), does not seem well known. There seems little other explanation for the
53
54 incoherence of results in two case scenarios involving diabetes mellitus with consensus for
55
56 ambulatory care in a diabetic child scheduled for inguinal hernia repair, but complete lack of
57
58 consensus for the simpler myringotomy and tube placement. Similar conclusions may be drawn as
59
60

1
2 to lack of knowledge regarding the fact that ambulatory anesthesia does not increase the risk of
3
4 developing a malignant hyperthermia in patients with malignant hyperthermia susceptibility (10-
5
6 12). The only consensus found in three scenarios involving malignant hyperthermia susceptibility
7
8 was that against ambulatory care in the context of fever of 38°C and strabismus repair, and the fever
9
10 may well have influenced the consensus against ambulatory care as much as malignant
11
12 hyperthermia susceptibility. Nor was there was consensus for ambulatory care in a scenario
13
14 involving isolated morbid obesity, despite the lack of evidence that it increases unanticipated
15
16 admission rates following ambulatory care in children, or that inpatient care improves outcomes.
17
18 This may be due to extrapolation of data describing predominantly respiratory peri-operative
19
20 complications in obese adults undergoing ambulatory anesthesia (10).
21
22
23
24

25
26 The survey did not identify consensus on the subject of fever, whether in isolation or associated
27
28 with co-morbidities. This is unsurprising as the literature is unhelpful on this subject. Similarly, no
29
30 consensus was found for children with active or recent upper respiratory tract infections. Although
31
32 increased peri-operative respiratory complications are observed in these contexts (13; 14), baseline
33
34 respiratory complication rates are low, uncommonly associated with serious morbidity (15) and
35
36 unaffected by the mode of anesthetic practices (16).
37
38
39

40 There was no consensus for or against ambulatory care for a toddler with OSA undergoing
41
42 circumcision. In contrast, OSA related morbidity in ENT patients seems well known, resulting in
43
44 consensus against ambulatory anesthesia. Indeed, OSA clearly increases peri-operative risk and
45
46 requires caution, particularly when associated with ENT surgery. OSA remains the most frequent
47
48 indication for unexpected readmission after tonsillectomy (17), although no increase in post
49
50 tonsillectomy complications has been demonstrated prospectively. A higher incidence of
51
52 postoperative respiratory complications requiring medical intervention has also been retrospectively
53
54 found in children with OSA aged < 2 years (18). Accordingly, the American Academy of Pediatrics
55
56 recommends inpatient mode for children with OSA aged < 36 months, and all children with severe
57
58 OSA (19), while the French Society of Anesthesia and Intensive Care (Société Française
59
60

1
2 d'Anesthésie et de Réanimation : SFAR) and the ADARPEF both recommend inpatient care for
3
4 tonsillectomies in children with severe OSA (20).
5

6
7 The recent literature on sickle-cell disease and pediatric ambulatory care is limited to 1 paper
8
9 claiming that specific high risk situations including anesthesia requires “adequate responses” (21).
10
11 Responders reported consensus against ambulatory anesthesia in a child with 58% HbS scheduled
12
13 for adeno-tonsillectomy & bilateral myringotomy and tube placement.
14

15
16 No consensus was found for cases involving isolated unclassified encephalopathy and minor
17
18 laparoscopic surgery in a toddler (the latter probably too uncommon given the patient's age). There
19
20 was however consensus to proceed with ambulatory anesthesia in scenarios involving aggressive
21
22 autism, Lowe's syndrome (a rare disease seemingly known to responders despite 7 non-responses),
23
24 and an adolescent given non-steroidal anti-inflammatories the day before an arthroscopy. Consensus
25
26 was also found against an asthmatic child having suffered an attack the day before adeno-
27
28 tonsillectomy.
29
30

31
32 In summary, although the literature is often unhelpful in deciding for or against ambulatory care,
33
34 pediatric anesthesiologists also seemed uninformed about the information that does exist. Despite
35
36 studies showing that peri-operative surgical complication rates are higher than those related to
37
38 previous medical conditions (22), lack of knowledge with respect to specific pathologies and their
39
40 impact upon risk in ambulatory anesthesia seems to hinder the employment and development of
41
42 ambulatory pediatric anesthesia. The findings from this section of the survey imply more education
43
44 is needed in determining suitability for pediatric ambulatory surgery. Although life-threatening
45
46 complications are rare in ambulatory pediatric anesthesia, indications for inpatient care should be
47
48 systematically reviewed using relevant journals, and cross-referenced with morbidity/mortality
49
50 studies in order to improve patient selection criteria and peri-operative management and reduce
51
52 unnecessary hospitalizations. However, although there is room for education for cases where there
53
54 is good evidence, the majority of non-consensual scenarios involved situations for which the
55
56 literature is ambiguous implying opinions vary and thus it would be inappropriate to proscribe
57
58
59
60

1
2 practice in these situations. In these scenarios, further studies are required in the field of pertinent
3 complications, their incidence, and associated risk factors.

4
5
6
7 Fear of ambulatory care planning failure seems to negatively influence care providers. Failure and
8 cancellation have consequences, including the economic and emotional impact upon children and
9 parents (23), surgical team underemployment, and futile administrative effort. A balance needs to
10 be found, maximizing the use of ambulatory care for appropriate patients, while scheduling
11 inpatient care for patients with risk factors for complications requiring hospitalization, thus
12 avoiding the costs and stress associated with unplanned admissions.
13
14
15
16
17
18
19

20 **Conclusion**

21
22 Despite its limits, this survey reveals that ADARPEF members practicing in France: (i) in general
23 follow French CNCE/ADARPEF guideline recommendations, but, (ii) do not sufficiently use
24 ambulatory anesthesia in children, (iii) prescribe post-operative analgesics poorly, and (iv)
25 generally demonstrate lack of consensus as to the appropriateness of ambulatory care in common
26 clinical situations.
27
28
29
30
31
32
33

34
35 More information must be provided to pediatric anesthetists to improve the quality and use of
36 ambulatory pediatric anesthesia.
