ABSTRACT: Leber Congenital Amaurosis (LCA), the most severe inherited retinal dystrophy, is genetically heterogeneous, with 14 genes accounting for 70% of patients. Here, 91 LCA probands underwent LCA chip analysis and subsequent sequencing of 6 genes (*CEP290*, *CRB1*, *RPE65*, *GUCY2D*, *AIP1* and *CRX*), revealing mutations in 69% of the cohort, with major involvement of *CEP290* (30%). In addition, 11 patients with early-onset retinal dystrophy (EORD) and 13 patients with Senior-Loken syndrome (SLS), LCA-Joubert syndrome (LCA-JS) or cerebello-oculo-renal syndrome (CORS) were included. Exhaustive re-inspection of the overall phenotypes in our LCA cohort revealed novel insights mainly regarding the *CEP290*-related phenotype. The *AHI1* gene was screened as a candidate modifier gene in three patients with the same *CEP290* genotype but different neurological involvement. Interestingly, a heterozygous novel *AHI1* mutation, p.Asn811Lys, was found in the most severely affected patient. Moreover, *AHI1* screening in five other patients with *CEP290*-related disease and neurological involvement revealed a second novel missense variant, p.His758Pro, in one LCA patient with mild mental retardation and autism. These two *AHI1* mutations might thus represent neurological modifiers of *CEP290*-related disease. ©2010 Wiley-Liss, Inc.

INTRODUCTION

Leber Congenital Amaurosis (LCA, MIM[204000]) was first described as a congenital type of retinitis pigmentosa (RP). Approximately 20% of all blind children are thought to suffer from this disease. Phenotypic features include a congenital onset, severely reduced or absent electroretinogram (ERG), nystagmus, the oculo-digital sign, and a fundus aspect varying from normal to severely atrophic. Two main types of LCA have been reported, based on the presence or absence of photophobia, night blindness, hyperopia, macular/peripheral retinal abnormalities and measurable visual acuity (Hanein et al., 2004; Hanein et al., 2006). LCA displays variable expression, and seems to represent the extreme and severe end of a spectrum of inherited retinal disease.

LCA is predominantly inherited in an autosomal recessive manner. So far, one locus - *LCA9* (Keen et al., 2003) - and the following 14 genes have been identified: *GUCY2D* (Perrault et al., 1996), *RPE65* (Marlhens et al., 1997), *CRX* (Freund et al., 1998), *AIPL1* (Sohocki et al., 2000a), *RPGRIPI* (Dryja et al., 2001), *CRB1* (den Hollander et al., 2001), *RDH12* (Perrault et al., 2004), *IMPDH1* (Bowne et al., 2006), *CEP290* (den Hollander et al., 2006), *RD3* (Friedman et al., 2006), *LCA5* (den Hollander et al., 2007) and *SPATA7* (Wang et al., 2009), with the involvement of *TULP1* (Hagstrom et al., 1998) and *LRAT* (Thompson et al., 2001) under debate. Mutations in these genes account for ~70% of all LCA cases. Several of them are also implicated in other retinal dystrophies: *CRB1*, *RPE65*, *RDH12* and *SPATA7* are associated with both LCA and early-onset retinal dystrophy (EORD), which often overlap (Gu et al., 1997; den Hollander et al., 1999; Janecke et al., 2004; Wang et al., 2009).

Several subtypes of LCA can be considered part of the ciliopathies, as four disease genes - *TULP1*, *RPGRIPI*, *CEP290* and *LCA5* - encode ciliary proteins. Since cilia are present throughout the whole body, mutations in these genes may cause a broad phenotypic spectrum. One of the best examples is *CEP290*, the most frequently mutated gene in the western European LCA population. In addition to LCA, *CEP290* is associated with Joubert syndrome (JS, MIM[213300]), Senior-Loken syndrome (SLS, MIM[266900]), Meckel-Grüber syndrome (MKS, MIM[249000]) and Bardet-Biedl syndrome (BBS, MIM[209900]); a range of clinically and genetically heterogeneous ciliopathies (Sayer et al., 2006; Valente et al., 2006b; Baala et al., 2007; Brancati et al., 2007; Helou et al., 2007; Leitch et al., 2008). Recent studies suggest that modifiers may play a role in the pathogenesis of ciliopathies (Leitch et al., 2008; Khanna et al., 2009; Louie et al., 2010).

Establishing a molecular diagnosis for LCA is not only important in the context of genetic counselling and clinical prognosis, but is also essential in view of future gene therapy. Recent Phase I clinical trials for *RPE65* gene replacement therapy provide hopeful prospects for the treatment of inherited retinal dystrophies (Bainbridge et al., 2008; Hauswirth et al., 2008; Maguire et al., 2008; Cideciyan et al., 2009; Maguire et al., 2009). As such therapies are likely to be gene-specific, the development of robust clinical testing and efforts toward gene identification are of utmost importance.

Current diagnostic testing for LCA generally involves chip analysis that contains known mutations in the known LCA and EORD genes (Asper Ophthalmics, Estonia). Depending on the population, causal mutations are found in approximately 55% of all cases (Yzer et al., 2006). Only a limited number of laboratories subsequently screen an additional number of genes (Stone, 2007; den Hollander et al., 2008).

This study includes an extensive genetic survey in order to identify the molecular cause in 91 LCA probands mainly of Belgian origin, using LCA chip analysis for 8 to 13 genes and subsequent sequencing of the following genes: *CEP290* (MIM[610142]), *CRB1* (MIM[604210]), *RPE65* (MIM[180069]), *GUCY2D* (MIM[600179]), *AIPL1* (MIM[604392]) and *CRX* (MIM[602225]). In addition, exhaustive phenotyping was performed in all patients carrying mutation(s), and the *AHII* gene was screened for modifier alleles of *CEP290*-related disease.

MATERIALS AND METHODS

Patients

Ninety-one consenting subjects initially diagnosed with LCA were referred for molecular testing by an ophthalmologist and/or geneticist, mainly associated with the University Hospitals of Ghent, Leuven or Brussels. Eleven probands are born from a consanguineous marriage. The inclusion criteria for LCA were bilateral visual loss before the age of 6 months accompanied by nystagmus and an undetectable or significantly reduced ERG.

4 Coppieters et al.

Twelve patients presented with additional mental retardation and/or autistic behaviour. For 18 patients with an available Magnetic Resonance Imaging (MRI), the absence of a molar tooth sign (MTS) excluded the diagnosis of JS. In addition, genotyping was performed on 11 probands with EORD, (disease diagnosed beyond the first six months of life but before the age of three) and 13 with a retinal dystrophy in the context of JS (LCA-JS), SLS or cerebello-oculo-renal syndrome (CORS). These patients were not included during calculations of gene-specific contributions in isolated LCA. Genomic DNA and RNA were extracted from leukocytes using the Puregene DNA isolation kit (Gentra, Minneapolis, USA) and the RNeasy Mini kit (Qiagen) respectively, followed by cDNA synthesis with the iScript cDNA Synthesis kit (Bio-Rad). If available, parents and/or siblings were also genotyped. Seven of the patients were reported previously (Yzer et al., 2006; Brancati et al., 2007; Perrault et al., 2007). Patient notation was performed according to their clinical diagnosis (prefixes LCA, SLS, LCA-JS, CORS and EORD), with consecutive numbering in the order of the genes involved.

Genotyping

As a pre-screening method, all patients with either isolated LCA or EORD were analysed with a microarray containing 344 to 641 mutations in 8 (*GUCY2D*, *CRX*, *RPE65*, *CRB1*, *RPGRIP1*, *AIPL1*, *LRAT* and *MERTK*) to 13 (addition of *TULP1*, *LCA5*, *RDH12*, *CEP290* and *SPATA7*) LCA and EORD genes (LCA chip Versions 2004-2009; Asper Ophthalmics, Estonia) (<http://www.asperbio.com>) (Zernant et al., 2005). Each of the mutations found by the LCA chip was subsequently confirmed through Sanger sequencing. In case of a heterozygous mutation, the coding exons and intron-exon boundaries of the involved gene were sequenced.

Patients in whom no mutations were identified after LCA chip analysis were analysed through sequencing of all coding exons and intron-exon boundaries of *CEP290*, *CRB1*, *RPE65*, *GUCY2D*, *AIPL1* and *CRX*, the first five genes being the most frequently mutated in LCA. At the time the LCA chip did not yet include *CEP290* variants, stepwise targeted mutation analysis was performed prior to sequencing of the total coding region. We initially screened for the frequent c.2991+1655A>G mutation followed by four additional mutations: c.4723A>T (p.Lys1575X), c.5587-1G>C (splice site), c.5163del (p.Thr1722GlnfsX2) and c.3310-1_3310delinsAA (splice site). The first three mutations occurred multiple times in a previous study (Perrault et al., 2007); the latter was found in three patients with a heterozygous c.2991+1655A>G mutation in our population. *CEP290* was also screened at cDNA level in patients with only a single mutation in *CEP290*. To this end, cDNA screening using 16 overlapping primer sets was optimized. Four patients with *CEP290*-related LCA who presented with mental retardation, two patients with SLS, one patient with CORS and one patient with LCA-JS underwent sequencing of the *AHII* gene. For 13 patients with SLS/LCA-JS/CORS, molecular testing of *CEP290* was requested. Supp. Table S1 includes all primer sequences used in this study.

Mutation nomenclature

Mutation nomenclature uses numbering with the A of the initiation codon ATG as +1 (www.hgvs.org/mutnomen), based on the following RefSeqs: NM_201253.1 (*CRB1*), NM_000329.2 (*RPE65*), NM_000180.3 (*GUCY2D*), NM_014336.3 (*AIPL1*), NM_000554.4 (*CRX*), NM_025114.3 (*CEP290*), NM_152443.2 (*RDH12*), NM_020366.3 (*RPGRIP1*) and NM_001134831.1 (*AHII*) (<http://www.ncbi.nlm.nih.gov/nuccore>). All mutations and variants found in *CEP290* were submitted to the Locus-Specific Mutation Database *CEP290base* (<http://medgen.ugent.be/cep290base>) (Coppieters et al., 2010).

Evaluation of sequence changes

The presence of all mutations was confirmed on a second PCR product. Segregation analysis of disease alleles was performed if possible. Genomic DNA obtained from > 340 unrelated ethnically matched healthy individuals was used as a control panel. Thorough bio-informatic evaluation of novel variants was done using Alamut software (v.1.5). Variants were designated as "unclassified variant (UV)" if no consensus was seen in all prediction programs used. The Alamut output for missense changes was listed in Supp. Table S2.

Clinical evaluation of patients

After identification of the molecular cause, the clinical records were revisited, based on a clinical checklist comprising data on visual function, retinal appearance and associated (extra-) ocular features. When possible, ERG, fundus pictures, autofluorescence (AF) images and optical coherence tomography (OCT) were obtained. In

case of *CEP290*-related LCA, neurological (MRI) and nephrological data (kidney ultrasound [US], urinary and blood parameters) were obtained and evaluated.

RESULTS

Mutation screening strategy of known LCA genes

As a first step, 102 probands were subjected to LCA chip analysis (91 LCA and 11 EORD). In total, 30 sequence changes assigned as mutations by Asper Ophthalmics were identified in 47 individuals. Homozygous and compound heterozygous variants in one gene were each found in 13 patients; a single heterozygous variant was identified in 17 individuals. In addition, variants within two distinct genes were found in four patients. The zygosity of p.Glu1330X (*CRBI*) could not be determined in LCA-36. Confirmation of each mutation through direct sequencing identified two inconsistencies. At first, LCA-58 was genotyped heterozygously for the *AIPLI* mutation p.Trp278X by chip, while she was in fact homozygous. Secondly, a heterozygous p.Arg38AlafsX3 mutation in *AIPLI* (LCA chip version 2006) could not be confirmed in LCA-23. Instead, a heterozygous c.111C>T (p.=) variant was identified on the same nucleotide position. This miscall has previously been described (Henderson et al., 2007). In addition, subsequent sequencing of *GUCY2D* in LCA-51 revealed a heterozygous c.389del mutation that was not detected on the LCA chip. The variants c.2101C>T (p.Pro701Ser) (*GUCY2D*), c.3341A>G (p.Asp1114Gly) (*RPGRIP1*) (Vallespin et al., 2007a), c.286G>A p.Val96Ile (*AIPLI*) (Yzer et al., 2006) and c.1301C>T (p.Ala434Val) (*RPE65*) (Morimura et al., 1998) have already been reported as polymorphisms and were therefore discarded as mutations. Moreover, identification of the *GUCY2D* p.Pro701Ser variant in a homozygous state in both healthy parents from an LCA patient further supported its non-pathogenic nature. After the exclusion of these polymorphisms, variants were assigned to be mutations in 45 patients (39 LCA and 6 EORD).

Secondly, all patients with a heterozygous mutation identified through chip analysis were subjected to screening of the relevant gene. In addition, all patients with negative chip results underwent sequencing of 6 LCA genes. In the following sections, the molecular results are discussed in detail for each of the genes.

CEP290. *CEP290* was found to be the most frequently mutated gene in our cohort, accounting for 30% (27/91) of cases with isolated LCA (Table 1). Since the LCA chip did not contain *CEP290* variants at the onset of this study, only a fraction of currently known mutations were detected using this technique. The c.2991+1655A>G, c.4723A>T (p.Lys1575X) and c.3310-1_3310delinsAA mutations were the most recurrent, with gene-specific allele frequencies of 49%, 11% and 6%, respectively. Similar to previous studies, most of the mutations are either nonsense, frameshift or splice site mutations. Only two missense variants were identified, of which the pathogenic effect is currently uncertain (p.Ala1566Pro and p.Leu1694Pro) (Supp. Table S2). Overall, 13 novel *CEP290* mutations were identified to cause LCA. The complex allele c.3310-1_3310delinsAA has a predicted effect on splicing, which was confirmed by cDNA analysis (data not shown). The silent c.1824G>A change affects the last nucleotide of exon 18 and was also predicted to alter splicing (data not shown).

Since *CEP290* mutations may cause a phenotypic spectrum ranging from isolated LCA to more complex disorders, we analysed 13 additional probands suffering from LCA-JS, SLS or CORS. *CEP290* harbored mutations in seven of them (Table 1). Six probands carried known mutations, whereas a novel p.Thr2457AlafsX27 mutation segregated in family LCA-JS-2.

Sequencing of the entire coding region did not reveal a second mutation in LCA-27, while the pathogenic effect of one variant was uncertain in LCA-25 and LCA-26. Subsequent cDNA screening in LCA-25 and LCA-27 was normal, thereby making deep intronic splice site mutations or large exon deletions/duplications very unlikely. No RNA was available for LCA-26.

CRBI. Mutations in *CRBI* were found in 15 families with LCA (16%) and 5 families with EORD (Table 1). The LCA chip allowed the identification of a homozygous or compound heterozygous *CRBI* mutation in 15 probands (12 LCA and 3 EORD), and a heterozygous *CRBI* mutation in 3 patients. Sequencing of the whole coding region of *CRBI* in the latter revealed a known and novel mutation, respectively (LCA-29, p.Gln362X and LCA-34, c.4006-1G>T), and a novel unclassified variant (EORD-3, p.Asp491Val) on the second allele (Supp. Table S2). Sequencing of the total coding region identified compound heterozygous mutations in two additional

proband. In one of them, *CRBI* screening was exceptionally performed without prior LCA chip analysis, given clear clinical indications for a *CRBI*-related phenotype (EORD-2). Indeed, this patient was compound heterozygous for the known p.Cys948Trp mutation, and the novel p.Cys310Tyr variant, which is predicted to disrupt a disulfide bridge (Supp. Table S2). In addition, two sisters with LCA carried two novel frameshift mutations (LCA-41). As previously described, the p.Lys801X and p.Cys948Trp mutations were most frequent, showing gene-specific allele frequencies in the LCA cohort of 27% and 23%, respectively.

RPE65. Eight cases with LCA showed mutations in *RPE65* (9%) (Table 1). LCA chip analysis identified a homozygous *RPE65* mutation in LCA-43 and LCA-47, and two compound heterozygous mutations in LCA-49. In addition, a heterozygous mutation was detected in four patients through LCA chip analysis. Sequencing of *RPE65* in these individuals identified three novel mutations and the known p.Phe530LeufsX40 mutation which was not yet present on the LCA chip at the time (LCA-48). Although the evidence for a pathogenic nature of the novel mutation p.Trp331dup is not conclusive, segregation in patient LCA45a, her affected aunt LCA45b and her (healthy) parents sustains a causal role. The two other novel mutations result in a frameshift (LCA-46 and LCA-50). Following sequencing of the total coding region, one additional proband was found to be homozygous for the novel *RPE65* mutation p.Pro181Leu (LCA-44) (Supp. Table S2). Interestingly, segregation analysis of the mutations found in LCA-46 could only confirm segregation of p.Leu341Ser in the mother, suggesting that p.Ser121LeufsX6 occurred *de novo* (paternity confirmed).

GUCY2D. Mutations in *GUCY2D* were found in seven probands with LCA (8%) (Table 1). Five of them were identified with *GUCY2D* mutations using the LCA chip. One was homozygous for p.Phe565Ser (LCA-52), while three others carried p.Arg768Trp. One of the latter was homozygous (LCA-53); the other two were compound heterozygous for p.Phe565Ser (LCA-54) and the novel missense change p.Lys866Asn (LCA-55), respectively (Supp. Table S2). In addition, LCA-57 was heterozygous for the p.Pro575Leu variant that was previously identified in the mother of an LCA patient (Koenekoop et al., 2002). However, no second mutation was found. LCA-56 was compound heterozygous for the novel missense changes p.Glu196Val and p.Pro711Leu (Supp. Table S2). In addition, a novel splice site mutation was identified in LCA-51 (c.2577-2A>C).

AIPL1. Only two distinct *AIPL1* variants were detected through LCA chip analysis in five LCA patients (5%) (Table 1). The p.Trp278X mutation occurred homozygously in four probands (LCA-58 to LCA-61). In addition, a heterozygous p.Thr114Ile variant was found in proband LCA-62. Direct sequencing of the *AIPL1* gene identified the known variant p.Pro376Ser (missing signal on LCA chip). Segregation analysis in the parents, however, revealed a *cis*-allelic inheritance from the mother. No further mutations were detected following additional sequencing of *AIPL1* in other patients.

CRX. LCA chip analysis identified 2 *CRX* missense variants in two LCA patients (Table 1). The p.Tyr142Cys variant was previously described as a mutation (Vallespin et al., 2007a). Stone and colleagues, however, considered this variant as a polymorphism based on the estimate of pathogenic probability and the identification of this variant in a patient with two disease-causing alleles in another LCA gene (Stone, 2007) (LCA-63). The pathogenicity of the second variant p.Val242Met also remains unclear (LCA-64) (Swain et al., 1997; Rivolta et al., 2001; Chen et al., 2002). Given their uncertain pathogenic potential, both variants were discarded as mutations for further calculations.

RDH12. Mutation screening of *RDH12* was performed downstream of LCA chip results involving this gene. A heterozygous p.Ala269GlyfsX2 mutation was identified in two probands with EORD. Subsequent sequencing *RDH12* identified an additional novel missense change in both patients, p.Val233Asp (EORD-6) and p.Ser175Leu (EORD-7) respectively (Supp. Table S2). According to UniProt, the Ser175 residue might be a substrate binding site (<http://www.uniprot.org/uniprot/Q96NR8>). A known mutation located in the same codon, p.Ser175Pro, lacks the ability to catalyze the reduction of retinaldehyde to retinol *in vitro* (Lee et al., 2007). In addition, a homozygous p.Ala269GlyfsX2 mutation was identified in patient EORD-8, for which *RDH12* sequencing was performed prior to LCA-chip analysis (upon request).

RPGRIP1. Similarly, screening of *RPGRIP1* was performed in the context of LCA chip analysis. In one LCA patient, a heterozygous mutation was identified. Sequencing of *RPGRIP1*, however, did not identify a second mutation (LCA-65).

Deleted: As for *RDH12*, mutation

Deleted: (1%)

Deleted: the total coding region

Mutations in multiple LCA genes. For the assessment of the potential involvement of a second gene in LCA, only variants with significant pathogenic potential were taken into account (see above). Two patients with *CEP290*-related LCA displayed a heterozygous mutation in another LCA gene: LCA-16 was heterozygous for the known p.Arg85Cys mutation in *RPE65*, while LCA-20 carried the common p.Lys801X mutation in *CRB1*.

Deleted: considered

Identification of potential modifier alleles in the *AH1* gene

The *AH1* gene was sequenced as a candidate modifier gene in eight patients with *CEP290*-related LCA who presented with mental retardation. Four of them were diagnosed with LCA (LCA-3, LCA-20, LCA-23 and LCA-24); two patients also suffered from NPHP (SLS-2 and SLS-3) and in two other cases, the LCA phenotype was part of a JS diagnosis (CORS-1 and LCA-JS-3). A MTS was absent on brain imaging in two isolated patients with LCA (no data were available for LCA-20, LCA-24, SLS-2 and SLS-3).

A heterozygous novel *AH1* p.Asn811Lys mutation was found in the most severely affected patient CORS-1, out of three patients with the same *CEP290* genotype but different neurological involvement (SLS-2, SLS-3 and CORS-1). Moreover, *AH1* screening in the five remaining patients revealed a second heterozygous missense variant, p.His758Pro, in LCA-3. Conservation and *in silico* predictions for both changes suggest a possible effect on protein structure/function (Supp. Table S2). Interestingly, exonic splicing enhancer (ESE) predictions point to a change in ESEs for both variants (data not shown). Moreover, both changes are located in a conserved WD-40 repeat (<http://www.uniprot.org/uniprot/Q8N157>) and were absent in > 340 Belgian control individuals.

Deleted: 170

In addition, SLS-2 was found to be heterozygous for the known p.Ser1123Phe change. Although it concerns a potentially pathogenic variant that affects a phosphorylation site and is located in a highly conserved region (Dephoure et al., 2008), this change was considered a polymorphism because of its high frequency in the Dutch population and the observation that this change did not segregate in a family with JS (Valente et al., 2006a; Kroes et al., 2008).

Table 1: Mutations identified in 80 unrelated patients with LCA, using LCA chip analysis and direct sequencing of *CEP290*, *CRB1*, *RPE65*, *AIPL1*, *GUCY2D* and *CRX*.

Clinical findings

Extensive ophthalmological data (best corrected visual acuity [BCVA], refraction, ERG, visual fields, color vision testing, fundus aspect both with white light and autofluorescence imaging and the presence of nystagmus, night blindness, photophobia and additional features) as well as associated manifestations in patients with *CRB1*, *RPE65*, *GUCY2D*, *AIPL1*, *CRX*, *RPGRIP1* and *RDH12* mutations are summarized in detail in [Supp. Table S3](#). In addition, Figure 1 depicts several representative fundi from patients with an established molecular diagnosis. An MTS due to midbrain abnormalities with cerebellar vermis aplasia was demonstrated in five patients with JS-LCA/CORS and *CEP290* mutations (Figure 2).

Special attention was paid to the *CEP290*-related ocular phenotype, since this has been described in only a few LCA studies so far. It appeared that this phenotype displays only limited fundus alterations in the first few years of life. In a small subset of patients, no fundus abnormalities were obvious early on, while in the majority a marbled fundus and/or salt and pepper aspect was seen during the first decade. This aspect further evolved from young adulthood into progressive outer retinal atrophy in the midperiphery with relative sparing of the central macula. Abnormalities of the central macula were absent in our patient cohort, despite the impression that *CEP290*-related disease is probably of a cone-rod type (based on ERG findings and the occurrence of photophobia). Of note is the presence of a hyperautofluorescent ring around the central macula on AF imaging, observed in four patients starting from the age of six (LCA-2, LCA-3, LCA-7 and LCA-25). Mild intraretinal spicular pigment migration occurred in three patients at an age between 7 and 33 years old (LCA-JS-1, LCA-6 and LCA-7). This aspect became even more pronounced at the age of 49 in patient LCA-7, where a predominant spicular pigmentation was mixed with less frequent intraretinal pigment migration with a nummular aspect. Visual acuity of this group was mostly limited to light perception. In the few patients with better preserved central vision, basic color vision was present and visual fields varied from severely concentrically constricted (LCA-8) to sparing of the central 30° at an age of 49 (LCA-7) ([Supp. Table S3](#)).

Figure 2: Magnetic resonance imaging (MRI) showing characteristic molar tooth sign (MTS) in five patients with Joubert syndrome/cerebello-oculo-renal syndrome due to mutations in *CEP290* (all are axial sections through midbrain).

Images organized from left to right; arrows indicate MTS of midbrain present in all due to midbrain malformation with hypoplastic cerebellar vermis and midline cleft (all images are T1 weighted except for panel D, which is T2 weighted). A) CORS-1 at age 5 years; B) LCA-JS-1 at age 7 years; C) LCA-JS-2 II-1 at age 14 years; D) LCA-JS-2 II-2 at age 17 years and E) LCA-JS-3 at age 2 years.

age; mild predominantly spicular intraretinal pigmentation also increases with age; however, preservation of patches of normal peripheral retina are most striking feature; these patches remain over time.

DISCUSSION

Genotypes of the Belgian LCA population

In a cohort of 91 unrelated LCA patients, mainly originating from Belgium, a total of 61 different mutations (including 9 UVs) were found in 7 genes. **Homozygous or compound heterozygous mutations were detected in 65% (59/91) of probands, whereas only one heterozygous mutation could be identified in 4% (4/91) of probands.** In addition to isolated LCA, this study also identified mutations in eight probands with EORD and seven probands with syndromic LCA (SLS, LCA-JS and CORS) (Table 1).

LCA chip analysis proved to be a powerful initial tool as mutations were found in 41% (37/91) of patients with LCA. Subsequent sequencing of 6 genes (*CEP290*, *CRB1*, *RPE65*, *GUCY2D*, *AIPL1* and *CRX*) enabled us to identify mutations in an additional 28% of cases. **Of note, the majority of mutations found in the latter probands are now included in the LCA chip, increasing its detection rate to 65% if our cohort would have been analyzed using the latest version (v8, 641 variants).**

Segregation of disease alleles was demonstrated in 41 out of 43 families available, with two exceptions. The first one is LCA-62, in which the *AIPL1* variants p.Thr114Ile and p.Pro376Ser were located in cis on the maternal chromosome. This finding challenges a previous study proposing this genotype as causal in an LCA patient (Sohocki et al., 2000b). In the second case, only one of two mutations identified in LCA-46 was found in the mother but not in father, suggesting that the other mutation arose de novo (p.Ser121LeufsX6, non-paternity excluded) (Table 1). Of note, two different mutations in *CEP290* were identified in CORS-1, originating from a consanguineous marriage, which illustrates that assuming homozygosity in offspring from a consanguineous mating can be a potential pitfall for the identification of the causal defect (Table 1).

Our data demonstrate a key role for *CEP290* in the Belgian LCA population, as *CEP290* mutations were identified in 27 probands (30%). Although the prevalence of *CEP290* mutations is not this high worldwide (Simonelli et al., 2007; Vallespin et al., 2007b; Seong et al., 2008; Li et al., 2009; Sundaresan et al., 2009), this study corroborates the importance of *CEP290* in the Northwestern European population (den Hollander et al., 2006; Perrault et al., 2007). The second most frequently mutated gene in our LCA population was *CRB1* (16%), followed by *RPE65* (9%), *GUCY2D* (8%) and *AIPL1* (5%), which is in agreement with previous data (den Hollander et al., 2008). **The *RPGRIPI* gene – in this study only investigated with the LCA chip – accounted for less than 1% of the LCA population.**

In total, 30 novel mutations/variants were identified in this study (Table 1, Supp. Table S2). Interestingly, 5 out of 16 novel mutations in *CEP290* are located nearby known changes: c.384_385del (c.384_387del, c.381_382delinsT) (Baala et al., 2007; Perrault et al., 2007), c.2218-2A>C (c.2218-4_2222del and c.2218-15_2220del) (Sayer et al., 2006; Stone, 2007), c.3310-1_3310delinsAA (c.3310-1G>C) (Tory et al., 2007), c.5519_5537del (c.5515_5518del) (Sayer et al., 2006) and c.5865_5867delinsGG (c.5866G>T) (den Hollander et al., 2006). A similar observation was made for *RDH12*, in which the novel mutation p.Ser175Leu affects the same codon as the known mutation p.Ser175Pro (Perrault et al., 2004). Overall, these regions/codons might be more prone to mutational events.

For several genes, a limited number of recurrent mutations made up the majority of mutated alleles. This was certainly the case for *CEP290*, in which c.2991+1655A>G was found in 89% of all LCA patients with *CEP290*-related pathology. Together with p.Lys1575X and c.3310-1_3310delinsAA, a significant fraction of mutated alleles was identified in the LCA population (35/53 alleles). So far, p.Lys1575X has only been found in patients originating from northern France (Perrault et al., 2007) or Belgium (Brancati et al., 2007). This potential founder effect is supported by our study, since all patients who carry p.Lys1575X live in Flanders (northern part of Belgium). A similar regional prevalence was seen for p.Alal832ProfsX19, which was inherited from the Greek father of LCA-16. The same mutation occurred in an Italian patient with CORS (Brancati et al., 2007) and in two consanguineous families of Kosovar-Albanian and Kosovar origin with MKS, sharing a common haplotype (Frank et al., 2008). For the other genes, the following mutations presented with a gene-specific allele-frequency of at least 20% in the LCA population: p.Lys801X (*CRB1*, 27%), p.Cys948Tyr (*CRB1*, 23%), p.Phe530LeufsX40

(*RPE65*, 25%), p.Arg768Trp (*GUCY2D*, 31%), p.Phe565Ser (*GUCY2D*, 23%) and p.Trp278X (*AIPL1*, 89%). The presence of all but one of these mutations on the LCA chip significantly contributed to its high detection rate.

In six LCA patients, only one mutation was found after sequencing of the gene apparently involved following chip testing. Notably, we might have failed to detect deep intronic and regulatory mutations or multi-exon deletions, as [were](#) recently demonstrated in *CEP290* (Travaglini et al., 2009). In addition, it cannot be excluded that the phenotype is caused by mutations in a different gene, as [was](#) the case for LCA-20. Furthermore, new mutations in the other known genes cannot be [ruled out](#) here. Their contribution is expected to be limited however, taking into account the high detection rate obtained using the current strategy. Finally, these patients may carry mutations in as yet unknown genes.

Phenotypes of the Belgian LCA population

In addition, the phenotypes of patients with a molecular diagnosis were extensively studied. For all genes, nystagmus and hypermetropia were recurrent features. The oculodigital sign (plus [enophthalmos](#)) was often seen in all but *RPE65*-related LCA patients. A relatively higher incidence of both keratoconus and cataract was seen in the *CRB1*-related group, which may reflect secondary effects of a more severe retinal dystrophy compared to other genes. Indeed, several retinal abnormalities such as macular atrophy and intraretinal pigment migration already became apparent in the first decade of life in patients with *CRB1*-related disease, [being](#) earlier than generally seen for the other genes. In addition, a yellowish discoloration of the central macula was often observed. However, this feature is not entirely gene-specific, since it also occurred in a patient carrying *RDH12* mutations (EORD-7). This feature may be due to more severe outer retinal atrophy in the macula in *CRB1*- and *RDH12*-related disease, which may cause more intense scleral light reflection due to less absorption by the atrophic retinal pigment epithelium, with consequent highlighting of the macular luteal pigment.

The *RPE65*-related phenotype proved to be typically associated with a fundus appearance which is essentially normal during first years and displays only later on fundus alterations which are initially mild. Visual acuity is generally somewhat better than that seen in *CRB1*-related LCA. However, it seems to be the relatively slow evolution of the phenotype which makes it particularly suitable for therapeutic intervention (Bainbridge et al., 2008; Hauswirth et al., 2008; Maguire et al., 2008). For two patients from our cohort ([LCA-47 and LCA-49](#)), *RPE65* gene-replacement therapy resulted in better visual function (Maguire et al., 2009). In addition, two patients with *RPE65* mutations reported a period of increased visual function, possibly reflecting postnatal physiological cone maturation (LCA-44 and LCA-47) (Koenekoop et al., 2007). Hanein et al. classified both *CRB1*- and *RPE65*-related LCA as rod-cone dystrophies because of a predominant occurrence of night blindness (Hanein et al., 2004). All *RPE65*-related phenotypes in this study correspond to this classification. In the *CRB1*-group, however, six patients with LCA and two with EORD also suffered from photophobia, [even](#) before the onset of night blindness in EORD-3.

Similarly, the *GUCY2D*-related phenotype was found to have only limited fundus abnormalities. Although this phenotype was previously categorized as cone-rod dystrophy, one patient in our cohort had severe night blindness before photophobia became apparent (LCA-54).

In the patients with *AIPL1* mutations, an RP-like phenotype emerged by their teenage years at the latest, and a maculopathy with (partial) outer retinal atrophy was typically present in the majority of cases (Dharmaraj et al., 2004).

A unique feature of *RDH12*-related early-onset dystrophy was the occurrence of areas with complete preservation of the chorioretina in the retinal periphery, alternating with regions of total atrophy (EORD-7).

Notably, our study is one of the first reporting on the ocular phenotype of a larger group of LCA patients with *CEP290* mutations ([Supp. Table S3](#)). In keeping with previously reported findings (Perrault et al., 2007), it appeared to be that of a severe cone-rod type retinal dystrophy. Visual acuity was mostly limited to light perception, as recently described (Walia et al., 2010). Interestingly, a limited subset of patients displayed no obvious retinal abnormalities in the first years of life. In general, the fundus contained either small white dots or, more frequently, a marbleized or salt and pepper aspect in the first to second decade. In two patients aged 18 and 49, predominant spicular pigment migration was observed (LCA-6 and LCA-7), in contrast to the reported nummular pigmentation in one patient in the fourth decade (den Hollander et al., 2006). In one patient, nummular pigmentation was [described](#) in the first decade (LCA-10). Interestingly, a more severe phenotype was seen in LCA-20, who carried a heterozygous *CRB1* null allele on top of two mutations in *CEP290*.

Extra-ocular features of *CEP290*-related LCA and potential modifier alleles in *AH11*

Several patients with *CEP290*-related retinal dystrophy showed additional systemic features. Two patients with isolated LCA had several symptoms suggestive of renal dysfunction (LCA-3 and LCA-23, [Supp. Table S3](#)). LCA-3 suffered from growth retardation, polydipsia, enuresis nocturna and diurnal incontinence. Kidney US at the age of seven, however, was normal. In LCA-23, kidney US at the age of three revealed increased echogenicity and kidneys without clear cortico-medullary differentiation. Despite this observation, no clinical nephrological manifestations were present at the age of 17. Since the age of onset of end-stage renal disease caused by *CEP290* mutations may exceed the age of 20 (Helou et al., 2007; Tory et al., 2007), a close nephrological follow-up of these patients is required. Interestingly, both of these patients carry the recurrent c.2991+1655A>G mutation, which so far has only been reported in LCA patients without any other associated pathology. Of note, kidney US was available for only a subset of patients, and in general performed very early in life, when developing kidney disease might be difficult to detect.

In addition, four patients suffered from recurrent otitis media (OM) (LCA-5, SLS-1, SLS-3 and CORS-1, [Supplementary Table 2](#)). Although this is common in childhood, it is worth mentioning that it is also a clinical manifestation often seen in primary ciliary dyskinesia (PCD), a genetically heterogeneous disorder of motile cilia (Leigh et al., 2009). In a few cases, PCD with OM was associated with X-linked RP, caused by mutations in *RPGR* (Shu et al., 2007). Notably, *RPGR* is a centrosomal protein that interacts with *CEP290* (Chang et al., 2006). Moreover, loss-of-function experiments of *CEP290* in zebrafish caused developmental abnormalities of the otic cavity (Sayer et al., 2006).

Strikingly, 33% of patients with *CEP290*-related isolated LCA presented with mental retardation and/or autism, in contrast to only 8% of patients with mutations in the other genes. Subtle brain abnormalities such as broadened lateral ventricles were seen on MRI in some patients. Of note, brain imaging was not available for a subset of patients. Additional neurological manifestations included movement abnormalities (LCA-21), and dyspraxia and balance/coordination problems (LCA-18), the latter of which was also evident in two patients with syndromic *CEP290*-related LCA (SLS-2 and CORS-1) ([Supp. Table S3](#)).

Taken together, these extra-ocular manifestations fit well into the broad clinical spectrum of *CEP290* mutations, varying from isolated LCA to the lethal MKS. In addition, the *CEP290* allelic spectrum is highly complex. Mutations associated with isolated LCA in this study were previously reported in other ciliopathies (Table 1), albeit always in compound heterozygosity with a different mutation in the distinct phenotypes. Moreover, identical *CEP290* genotypes can display interfamilial variable expressivity and intrafamilial variation of the neurological phenotype was observed in several families with *CEP290*-related pathology (Coppieters et al., 2010). The complexity of *CEP290*-related disease is further illustrated by two cases from this study.

The first one is SLS-1, homozygous for p.Trp7Cys. Valente and coworkers identified the same mutation in patient with CORS, also of Pakistani origin (COR22, II:1). Despite a similar ocular and renal phenotype, both patients significantly differ in their neurological phenotype. A second and even more pronounced example is the variability in both nephrological and neurological involvement in three unrelated patients with the same p.Lys1575X/p.Arg1465X genotype (SLS-2, SLS-3 and CORS-1). Patients SLS-3 and CORS-1 displayed a similar clinical course of renal disease, with renal failure at the age of 16 and 14 years, respectively. In contrast, renal insufficiency in patient SLS-2 was not substantiated until the age of 30 ([Supp. Table S3](#)). Neurological signs of these three patients ranged from a mild mental handicap (SLS-2) over severe autism in combination with moderate mental retardation (SLS-3) to severe mental retardation associated with ataxia and a MTS (CORS-1). An MRI was not available for the other two patients, however.

The *AH11* gene was screened as a candidate modifier gene in these three patients. Strikingly, CORS-1, with the most severe nephrologic and neurologic phenotype, carries a heterozygous novel p.Asn811Lys mutation in *AH11*, which was absent in the two other patients. Upon screening of *AH11* in five additional patients with *CEP290*-related disease and neurological involvement, a novel missense variant, p.His758Pro, was identified in LCA-3. Mutations in *AH11* encoding Joubertin are responsible for JS, with retinal involvement in 75% and renal involvement in less than 10% of all *AH11*-associated patients (Kroes et al., 2008). Interestingly, both p.Asn811Lys and p.His758Pro affect conserved residues and are located in the predicted WD40-repeat, a domain conserved across all eukaryotes, mediating functions such as vesicular trafficking (Li and Roberts, 2001). Since *AH11* and *CEP290* appear to be in the same pathway through their interaction with *rab8a*, mutations in one of both genes

may modify a phenotype caused by the other (Kim et al., 2008; Tsang et al., 2008; Hsiao et al., 2009). Tory and colleagues already suggested a similar potential epistatic effect of *CEP290* and *AH11* mutations on phenotypes related to *NPHP1*, encoding another interactor of AH11 (Tory et al., 2007; Eley et al., 2008). Strikingly, one of the *AH11* variants they described as a potential modifier for neurological involvement in patients with *NPHP1* mutations, p.Arg830Trp, was recently identified as a modifier allele for retinal degeneration in patients with *NPHP1*, independent of a primary *NPHP1* mutation (Louie et al., 2010). Of note, four out of seven patients in the study from Tory and coworkers carrying p.Arg830Trp displayed visual impairment, with one blind individual (Tory et al., 2007). The p.Arg830Trp variant might affect AH11 complex stability/formation (Louie et al., 2010). The variants identified here, assumed to represent a neurological modifier in patients with LCA, might disrupt interactions with other proteins, thereby influencing AH11 function in other organ systems.

Overall, a molecular diagnosis of *CEP290* mutations might have considerable consequences towards the clinical prognosis of an individual. Given the potential involvement of ciliary modifiers and the presence of cilia throughout the whole body, the development of various additional clinical manifestations should be taken into account. As for LCA, both children and (young) adults should have a long-term close clinical neurological and nephrological follow-up, since some features have a later onset.

In conclusion, molecular testing identified mutations in 69% of our LCA cohort, with a major involvement of CEP290. Detailed phenotyping of all patients with a molecular diagnosis revealed novel insights, mainly into the *CEP290*-related retinal phenotype, which is well documented for the first time in a larger patient group. The variable age-of-onset of the extra-ocular features emphasizes the importance of long-term clinical follow-up of LCA patients with *CEP290* mutations. Moreover, the identification of potential modifiers of *CEP290*-related disease might contribute to a refined prognosis based on a molecular diagnosis. Finally, our findings fit with previous observations suggesting that the phenotype of ciliopathies is most likely determined by the synergistic effect of all variants occurring in the ciliary proteome.

Supplementary Table S1: Exon-flanking primers for the amplification of the human *CEP290*, *CRB1*, *RPE65*, *GUCY2D*, *AIPL1*, *CRX*, *RDH12*, *RPGRIP1* and *AH11* genes and for the c.2991+1655A>G mutation in *CEP290*.

MUTATION IN BRIEF

HUMAN MUTATION

Supplementary Table S2

Gene	Nucleotide change	Amino acid change	Domain/Region	PolyPhen		SIFT			Grantham score	Nucleotide conservation	Amino acid conservation	Remarks
				Prediction	PSIC score difference	Prediction	Score	Median sequence conservation				
<i>CEP290</i>	c.5081T>C	p.Leu1694Pro UV	Coiled coil	Possibly damaging	1.995	Affect protein function	0.00*	3.44	98	Weakly conserved (score: 0.0)	Moderately conserved (considering 12 species)	
<i>CEP290</i>	c.4696G>C	p.Ala1566Pro UV	Coiled coil	Possibly damaging	1.638	Tolerated	0.10	3.44	27	Highly conserved (score: 1.0)	Highly conserved, up to Frog (considering 12 species)	
<i>CRB1</i>	c.929G>A	p.Cys310Tyr	EGF-like 8, extracellular domain	Probably damaging	3.761	Affect protein function	0.00*	3.96	194	Highly conserved (score: 1.0)	Highly conserved, up to Cow (considering 8 species)	Disruption of annotated bond formation site (PolyPhen)
<i>CRB1</i>	c.1472A>T	p.Asp491Val UV	Laminin G-like 1, extracellular domain	Benign	1.410	Affect protein function	0.01*	3.96	152	Highly conserved (score: 1.0)	Weakly conserved (considering 8 species)	
<i>RPE65</i>	c.253C>T	p.Arg85Cys		Probably damaging	2.476	Tolerated	0.05	2.90	180	Highly conserved (score: 1.0)	Moderately conserved (considering 18 species)	
<i>RPE65</i>	c.542C>T	p.Pro181Leu		Probably damaging	2.956	Affect protein function	0.04	2.90	98	Highly conserved (score: 1.0)	Highly conserved, up to Fruitfly (considering 18 species)	Located next to metal ion binding site (UniProtKB)
<i>GUCY2D</i>	c.587A>T	p.Glu196Val UV	Extracellular domain	Possibly damaging	1.650	Affect protein function	0.00*	4.32	121	Weakly conserved (score: 0.3)	Highly conserved, up to Opossum (considering 10 species)	
<i>GUCY2D</i>	c.1724C>T	p.Pro575Leu	Cytoplasmic	Benign	1.433	Affect	0.00*	4.32	98	Weakly	Highly	rs28743021

Supplementary Table S2: *in-silico* predictions of the novel missense variants and known unclassified variants identified in this study using the Alamut software.

Alamut provides for each variant the HGVS nomenclature and a nucleotide conservation score which was computed at UCSC from 17 vertebrates and has a range between 0 and 1 (<http://genome.ucsc.edu/cgi-bin/hgTrackUi?g=multiz17way>). For missense variants, Alamut calculates the Grantham distance and automatically fills in queries for PolyPhen and SIFT prediction servers, based on the UniProt protein identifiers and FASTA sequences of several orthologs, respectively. In addition, information on topological as well as functional domains and variations (VAR) was extracted from the UniProtKB database using the following identifiers: O15078 (*CEP290*), P82279 (*CRB1*), Q16518 (*RPE65*), Q02846 (*GUCY2D*), Q9NZN9 (*AIPL1*), O43186 (*CRX*), Q96NR8 (*RDH12*) and Q8N157 (*AHII*) (<http://www.uniprot.org/uniprot/>). Variants were designated as “unclassified variant (UV)” if no consensus was seen in all prediction programs used. *These substitutions may have been predicted to affect function just because the sequences used were not diverse enough.

Supplementary Table S3 – Part I

Gene	Patient n°	Gender	Night Blindness	Photophobia	ERG	Color vision	Fundus aspect	Other features
CEP290 p.[Cys998X]+ [Cys998X]	LCA-1	M			Absent (4mo)		Optic disc pallor Retinal vessel attenuation Normal macula	
CEP290 p.[Cys998X]+ [Cys998X]	LCA-2	M		Mild	Absent (5mo & 1.5yrs)		Pigmentary retinopathy Normal macula (6yrs) Retinal vessel attenuation Salt and pepper alterations Pseudopapilledema HyperAF ring around macula (14yrs)	Eyepoking
CEP290 p.[Cys998X]+ [Arg108X]	LCA-3	M	+	+	Absent (4mo)	+ (6yrs)	Normal optic discs Retinal vessel attenuation Normal peripheral retina Beginning of hyperAF around macula (6yrs)	Eyepoking Enophthalmos
CEP290 p.[Cys998X](+ [Gln899X]	LCA-4	F			Absent (2yrs)		Retinal vessel attenuation Tapetal reflex of posterior pole Pseudopapilledema

Supplementary Table S3: Clinical data of 80 patients with mutation(s) in one of the LCA genes.

If available, the age of the first and last measurement is mentioned between brackets. A question mark indicates an uncertain status. [Blank fields indicate features for which no information could be obtained.](#) Clinical data on the two patients included in the Phase I clinical trial for *RPE65* gene-replacement therapy (LCA-47 and LCA-49) concern the period preceding therapy. Characteristics described in "Other features" are binocular, if not mentioned otherwise.

Abbreviations used: N°, number; cons, consanguinity; nyst, nystagmus; BCVA, best corrected visual acuity; OD, right eye; OS, left eye; ODS, both eyes; ERG, electroretinogram; VF, visual field; MTS, molar tooth sign; [MRI, magnetic resonance imaging](#); MR, mental retardation; NPHP, nephronophthisis; SE, spherical equivalent; +, present; -, absent; yr(s), year(s); mo, month(s); W, week(s); REM, roving eye movements; HM, hand motion; LP, light perception; NLP, no light perception; CF, counting fingers; AF, autofluorescence; OCT, optical coherence tomography; US, ultrasound; SIDS, sudden infant death syndrome; conc constr, concentrically constricted; G, green; B, blue; R, red; O, orange; P, pink; RPE, retinal pigment epithelium; PPRPE, preserved para-arteriolar retinal pigment epithelium; astigm, astigmatism; loc, localization; CRD: cone-rod dystrophy; SCP: subcapsularis posterior; dev del: developmental delay; MEI: middle ear infections; RDI: renal diabetes insipidus; CKD5: renal failure; RTx: transplantation.
