Abstract—Broadband access to the Internet at home was the first step in the emergence of so called Home Networks. In a close future, the number of appliance connected will rise and the network will become the home backbone. This lead us to a mesh architecture, in which routing will be mandatory. This paper introduces a complete system to, first, pilot the forwarding in order to ensure a proper quality of experience; and secondly to monitor and diagnosis the network from the ISP-network in order to reduce OPEX. The system is based on the knowledge plane composed of agents embedded on devices.

Index Terms—Home Network, WiFi, HomePlug AV, Agent, QoS, Knowledge Plane, Ontology, Throughput estimation, Supervision

INTRODUCTION

The spread of broadband accesses and of digital TVs at home is boosting the emergence of so called Home Networks. Currently, Home Networks are only composed of a broadband gateway, a set-top box and the domestic PC. We expect in a close future IPTV, VoIP WiFi phones, PDA, mobile phones, sensors and even domestic appliances (refrigerator, security devices) to be connected as well.

Contrary to classical networks, the Home Network is not monitored nor configured by an administrator. The end-user is supposed to be a neophyte, without any network skills. This implies strong constraints and the network needs to implement self-* functionalities, mainly:

- self-configuration: a new device should be easy to connect;
- self-healing: link disruption or device failures must be transparent for the end-user, if possible;
- self-optimizing: the network must reconfigure itself to tackle potential resource shortage.

Those functionalities lead us to autonomic networks techniques, and mainly distributed ones.

In this paper, we first, in section I present a widely accepted Home Network architecture. However, to fit the requirements of self-* capabilities, he have used *Distributed Artificial Intelligence* as explained in II. In III we are presenting in details our solution and illustrate the testbed implemented IV, which complete the work presented in [1], [2]. The multi-agent system involved in those solutions is mostly the same which permits us, in V, to compare them and also classical ones. Finally, we are concluding this paper by pointing out some work that remain to be achieved in section VI.

I. HOME NETWORK DEFINITION

Major initiatives are working on the Home Network for several years now, in order to identify this emerging network, the use-case, the technologies to be involved and so on. The Home Network cannot be treated separately from its broadband access to the Internet.

A. Home Network overview

The Broadband Forum is one of the oldest workgroup that mainly focuses on the broadband access. However, since the last years, the Home Network evolution has been taken into account in terms of management. Therefore, the TR-069 [3] jointly with the TR-098 [4] describe and complete and powerful management architecture that tackles both the Home Gateway and others in-home devices. For instance the TR-104 [5] describe a data model for a VoIP end device. However, the Home Network architecture remains out of the scope of the Broadband Forum.

However, this last point is covered by the Home Gateway Initiative (HGI) which is working on defining a wide set of use cases, and on enumerating technical solutions that could be used in a future Home Network. The purpose of this initiative is to mutualize development effort. The main idea is to enable a user to connect all its devices smoothly. For instance, an user must be able to watch a movie stored on the living room DVR directly on its bedroom TV.

Regarding the application, the DLNA [6] (Digital Living Network Alliance) is focusing on the software part of the upcoming use. Devices, DLNA compliant, are able to communicate and exchange content, like in the previously mentioned use case. It is an extension of the UPnP architecture, where the service discovery and management is implemented. Moreover, it defines how audio or video stream should be transported on the network, for instance in terms of codecs.

B. Architecture

In nowadays architecture, several independant technologies are running, such as WiFi, DECT . . . However, the IP convergence is in progress, and the number of appliances connected will rise pointing out limitation of the star topology. Moreover, the Home Network will have to handle multiple technologies, such as WiFi, HomePlug AV, ZigBee, Ethernet, Bluetooth. . .

At the same time, the huge bandwidth increase of the broadband access enable users to enjoy 100 Mb/s or even more till the gateway. However, the WiFi alone cannot support such bandwidth, with a wide coverage. A simple and usual way to increase the overall bandwidth is to decrease even more cell range.

The foreseen architecture is taking into account those points, as *HNID*¹ are introduced. They have several functionalities, such as realizing a transparent bridge between technologies, and to extend wireless coverage. This defines 2 stages in the network.

The first level is a full-mesh backbone of those bridging devices. They can connect to each other using Ethernet, PLC, MoCA, or any wireless technology. Connection diversity introduces several path to reach any other bridge. A smart routing scheme can be used to ensure a proper QoS. Those devices can be seen as wireless extenders.

The second level is for end devices, that can connect directly to any bridge. The connection can be either wireless, or wired. The figure 1 presents a typical instantiation of the architecture.

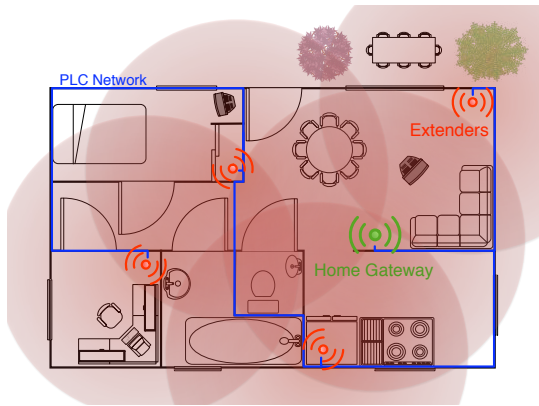

Fig. 1. Home Network architecture

C. Routing concerns

In the section I-B we have presented a mesh-hybrid architecture and the shared and perturbation sensitive transmission technology are tricky for the routing scheme.

Providing a routing protocol into such networks is not something difficult. There is a lot of routing protocols in the ad-hoc networks literature. The two mains are AODV [7] or OLSR [8]. Both are providing connectivity but without any QoS concerns. Some QoS extensions has been proposed, and recently the Hybrid Wireless Mesh Protocol (HWMP) has been standardized in the 802.11s. It introduces the Air Metric in order to introduce QoS in the routing protocol. Unfortunately, this protocol is only for WiFi ad-hoc networks, and does not encompass our problematic.

Moreover, in the Home Network we have to ensure a good Quality of Experience for the end user, so the HWMP approach is not sufficient anyway. Indeed, the network should

¹HNID: Home Network Infrastructure Device

not only select the best path available, but must spread out the load over different link so that each flow can enjoy the appropriate QoS.

As HWMP, we have adopted a layer 2 approach, based on STP, patched to permit our system to benefit from diversity. The STP is computing the main path and our system is able to change some path to avoid problematic situations, in which WiFi or HPAV links capacity is fading down, due to electromagnetic perturbations.

II. AGENT-BASED SOLUTION

As the architecture is complexe, we focus on autonomic networking, and more precisely on the knowledge plane concept implemented using a multi-agent system.

A. Knowledge plane

Introduced by [9], the knowledge plane can handle this complexity with a reasonable computation overhead. This plane was defined as

[...] a distributed and decentralized construct within the network that gathers, aggregates, and manages information about network behavior and operation.

The knowledge plane enables the network to implement the *self-** capabilities. Those requirements can be satisfied by a multi-agent system, which provides a decentralized approach to solve problems in complex environments [10]. The followings sections are introducing the agent (see II-B). We are finishing with section II-C and II-D in which we are describing the platform developed.

B. Agent overview

According to J. Ferber in [11], an *agent* can be a physical entity that can perceive and act on its environment. However, in our solution, we are using *intelligent agents* which can be defined as:

[an intelligent agent can] communicate with others, is autonomous and has skills to achieve its goals and tendencies.

Given this definition, we can exhibit some fundamental characteristics that must have an agent, as the work done by M. Wooldridge, in [12]. We denote autonomicity, social ability, reactivity and pro-activity. Developed agent are fitting most of those characteristics.

C. Ginkgo MAS

An intelligent agent, as defined in section II-B, is embedded on each network device as shown on figure 3. As previously explained, the Ginkgo agent, as an environment entity, has a knowledge representation, a perception of its environment which are both stored in a *situated view*, which is defined in [13].

It is mandatory to have a common vocabulary, both for the inter-agent communication and for the knowledge representation. Therefore an ontology has been developed. The figure 2 is

Fig. 2. Extract of the developed ontology

representing a subpart of the ontology using Unified Modeling Language (UML).

The inter-agent communication in the Ginkgo MAS is done via the *situated view* exchange. In other words, there is no *speaking act*², but only knowledge exchange. In a MAS, each agent has a partial view of its environment, the Ginkgo MAS has been designed so that an agent can only exchange his *situated view* with its directly connected neighbors (1-hop neighbors), as shown on figure 3.

D. Agent description

As shown on figure 4, agent capabilities are known as *behaviors* in the Ginkgo agent and are implemented using plug-in module. This set of behaviors is orchestrated by the *dynamic planner* which can start, stop, configure or even modify *behaviors*. The agent's knowledge is stored in the *situated view* which gather both remote and local knowledge. A *behavior* can sense or act on the hosting node using the *effector* and *sensor* interfaces.

III. GINKGO AGENT IN THE HOME NETWORK

In a Home Network context, agent's goal is to change quickly a path when the available resources does not meet flows requirements anymore. For now we have selected 2 different situations:

²A *speech act* is a intentional action performed within a communication. There are 5 types of *speaking act*: representative (*it's sunny*), directive (*Open the window*), commissive (*I'll assist to the meeting*), expressive (*I'm happy!*) and declarative (*The court declares the defendant not guilty*)

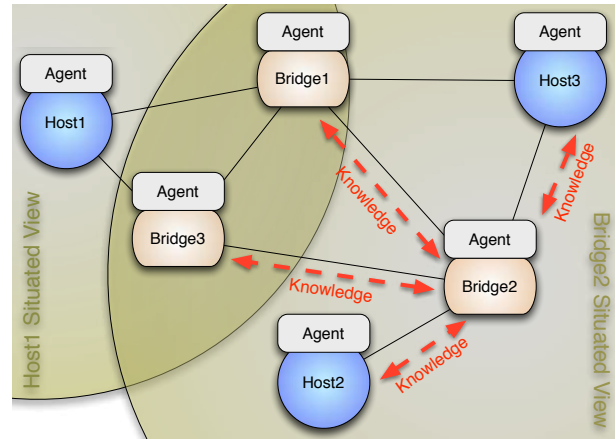

Fig. 3. Agents situated view concept

- link disruption: agents must change the path as soon as a link failure is detected;
- link quality degradation: agents must monitor the link quality, which means the available bandwidth³. If a noticeable degradation occurs, agents should change the path.

³This is an approximation to consider the QoS as a matter of bandwidth, but in most cases, the delay can be converted into extra bandwidth. This works if the delay is considered to be caused only by the serialization problem on the link.

Fig. 4. Agent operation

A. Building alternatives routes

In order to ensure a proper QoS in the Home Network, agents are maintaining alternatives routing tables so that they can switch quickly on those alternative if the main route does not succeed in carrying flows with the proper QoS. Those alternative are computed proactively, before any problem occurs.

The alternative route computation problem is similar to a task allocation one in a multi-agent system. Indeed, we can consider that finding an alternative route for a given destination, for a given service is a task. One the most used mechanism is a auction process. We have designed a sealed first-price auction, which is the auction in the common sense except that bidders can do only one bid without knowing other bids.

In more details, when an agent is detecting a new flow transiting through itself, he starts an auction which is then diffused through the situated view. In the meanwhile, when an agent is detecting a new auction in the situated view he tries to make a bid, regarding its resources. The first agent is waiting, and then selects the best bid available and registers the bidder as alternative next hop.

B. Link monitoring

Agents have to monitor the link status and performance in realtime, since they have to change as fast as possible the route. These constraints prevent us from using any active measurement methods. Everything must be done locally, in the hosting equipment. Moreover, the computation cost must be taken into account. In a first step of our work, we have elaborated methods as simple as possible⁴ to have references for any further works. This section discusses quickly the link status of each interface, and then the maximum available bandwidth estimation on WiFi, and finally on HomePlug AV links.

⁴The strongest approximation is the CSMA/CA effect on shared mediums.

1) *WiFi capacity estimation*: The algorithm used to estimate the WiFi bandwidth is at this step of our work very simple. In digital communication on noisy channel, the physical layer has to optimize the tradeoff between transmission bit rate and noise resilience on the channel. Some algorithms exist to approach this optimality, such as *Atsushi Onoe* [14] algorithm or *SampleRate* described in [15]. We are using this last one in our experiments⁵.

In order to operate successfully, this algorithm tries each modulation regularly to compute performance metric. In average, it generally uses to best modulation. The tricky point is to test appropriate modulations while not noticeably degrading overall performances. Our capacity estimation is based on those statistics, which are preprocessed before being input of a neural network which outputs the estimation.

The neural networks designed allows us to compute in real-time, with a quite small computation overhead, the available capacity on the link. The figure 5 shows the real value and the estimated one on the same graph.

2) *HomePlug AV capacity estimation*: As for the WiFi, the HomePlug AV physical layer as to adapt to the channel conditions by adjusting the modulation. However, despite the WiFi, there are 1152 frequencies available for the communication (see [16] for more information). The resulting modulation table is called the Tone Map, from which we can compute the channel capacity, called cap_c .

The HomePlug AV chip is also maintaining statistics on successfully transmitted frames⁶ and unsuccessfully ones. We are calling p_{suc} the proportion of successfully transmitted frames.

Since there is a high binary error rate on power lines, the HomePlug AV is using a powerful FEC⁷ system based on Turbo Codes. This adds overhead in blocks, so that the payload bandwidth is reduced by a factor p_{FEC} . As explained in [17], the factor value is $p_{FEC} = \frac{1}{2}$.

Finally, the bandwidth can be computed by the formula 1:

$$hpav_bw_{max} = p_{suc} \cdot p_{FEC} \cdot cap_c \quad (1)$$

In practice, we are smoothing this value so that high frequency variation are filtered out. The figure 5 is showing the performance of our bandwidth estimation.

C. Home Network supervision

The agent embedded on each device is acquiring knowledge, so it is simple to process knowledge so that the agent can extract noticeable changes. Those changes generates *events*, which are stored in each agent knowledge base. A dedicated neighborhood is defined in the situated view, so that each agent has the gateway as neighbor. This virtual neighborhood allows us to propagate event to the gateway. The gateway is then proposing a web-service API, as shown in figure 4.

⁵There is no strict limitation in using *SampleRate*, since most of the rate selection algorithm are using the same principle.

⁶In HomePlug AV, we prefer talking of blocks

⁷FEC: Forward Error Correction

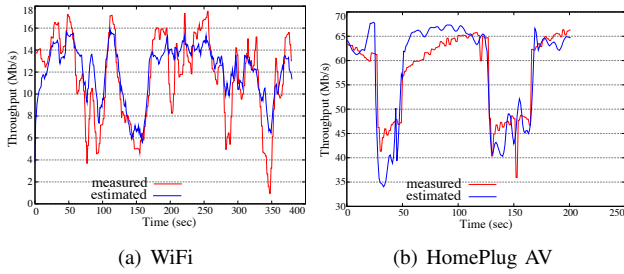

Fig. 5. Capacity estimation performance measurements.

Based on this knowledge distribution, any kind of webservice-enabled interface can access to this knowledge. In our system we are it in order the trace the network topology evolution along the network existence. This point is very helpful to diagnosticate problems, and identify the HNID from which it originates. The figure 6 is presenting some possible location of such interfaces, either, in the home, user-oriented, either, in the ISP network technician-oriented.

Fig. 6. Supervision architecture

IV. EXPERIMENTAL SET-UP

To experiment previous concepts, we have decided to setup a real testbed instead of using a simulator because many potential problems can be caused by implementation shortcuts. We have simplified the architecture to only 4 PC running GNU/Linux, in order to isolate problems quickly. The figure 7 is illustrating the testbed. This testbed implement both a basic (yet fonctionnal) supervision system and a QoS management one. This last one can support congestion scenario, or even perturbation ones, or even link disruption.

The testbed has already been presented in details in previous work, as perturbation scenarios. This paper will focus a the congestion scenario and the supervision implementation, as described in III-C.

Fig. 7. Testbed network

V. RESULTS

Given the network architecture presented in IV, we have realized two sets of experimentations which completes the one done in [2]. The first one was performed to check agents ability on detecting congestion on a link. The second was to check agents fonctionnality in their supervision task, such as history recording for instance.

A. Dealing with congestions

The system is able to monitor and to prevent from congestion over a given link. In this use-case, we are generating 2 flows, one video flow and one data flow. The video flow has to be protected from any congestion⁸. The figure 8 is illustrating the steps of the scenario.

Fig. 8. Congestion scenario

We have subjectively meseasured that the recovery time is under the half second. A complete measurement system has not been implemented yet. However, this is unperceivable on the video.

B. Supervision

We have developed a GUI to test our agent in the supervision function. Given the current topology and a list of noticeable events that had occur in the network, this interface is able to bactrace topology change, which mean that it can display the topology at any time.

⁸This is a goal given to the agent, via the dynamic planner

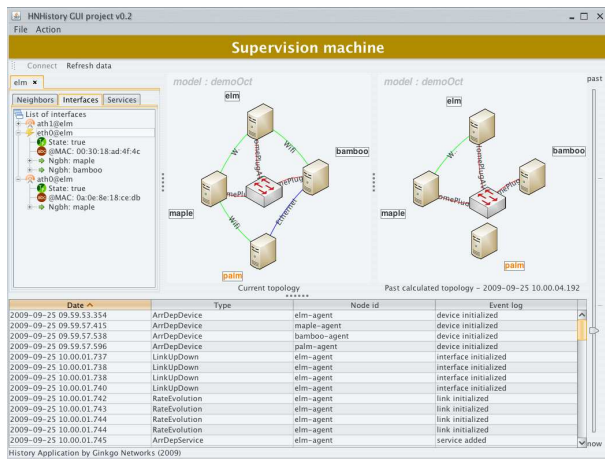

Fig. 9. Screenshot of supervision interface

VI. FUTURE WORKS

In previous sections, we have presented the fourth step of our work. The first one was to simulate the knowledge plane on an hand-made simulator to validate agents operations. We have setup, as a second step, a real testbed using a layer 3 routing protocol. Then we switch to the layer 2 approach of routing, and finally we have refined our system and added the supervision part. However a lot of work remains to be done, mainly regarding devices, extensive measurements and validation.

The architecture used for these experimentations is not yet complete, and one or two more PC will be added soon. This will enable more complex scenario, where agents will have to cooperate more intensively.

The passive QoS measurements both for WiFi or Home-Plug AV is still under study to improve the confidence in the estimator in one hand, and in the other hand to handle the CSMA/CA effect. At the same time the agent framework is used to simulate the CSMA/CA behavior. Moreover a statistical validation of the work is in progress to ensure that the routing is consistent in any situation.

For the WiFi, the WDS allows horizontal handovers but it has been eluded. Next work will be to integrate an algorithm to optimize the handover decision based on several criteria, such as the number of stations connected, the required bandwidth... The paper [18] presents the handover work on the same SMA platform that can be integrated with this work.

VII. CONCLUSION

Home Networks are using perturbation sensitive technologies due to their low deployment costs. However, users are requiring high quality of service as this network is the backbone of tomorrow homes. Dealing with this antagonism is not as simple as elaborating a new protocol. It as been experimented in V that a multi-agent system is able to master such complex environments.

Futhermore, if the number of device increase, the complexity is rising which may lead to unacceptable OPEX for the ISP.

An efficient supervision system has to designed at the same time. Our first work are already conclusive and points out that an autonomic solution based on a MAS is able to perform in those networks.

Our first real experimentations are quite satisfying as they can solve partially many problems. The real field is still far, but we believe that this work is nice first step, so that we will work to reach real Home Network devices.

ACKNOWLEDGMENT

The authors would like to thank the Ginkgo Networks developer team that helps them in implementing this solution, and one of our closest CELTIC/AutHoNe partner, Orange Labs for their guidelines and expertise on such networks.
