WATER WAVES OVER A ROUGH BOTTOM IN THE SHALLOW WATER REGIME

WALTER CRAIG, DAVID LANNES AND CATHERINE SULEM

Abstract. This is a study of the Euler equations for free surface water waves in the case of varying bathymetry, considering the problem in the shallow water scaling regime. In the case of rapidly varying periodic bottom boundaries this is a problem of homogenization theory. In this setting we derive a new model system of equations, consisting of the classical shallow water equations coupled with nonlocal evolution equations for a periodic corrector term. We also exhibit a new resonance phenomenon between surface waves and a periodic bottom. This resonance, which gives rise to secular growth of surface wave patterns, can be viewed as a nonlinear generalization of the classical Bragg resonance. We justify the derivation of our model with a rigorous mathematical analysis of the scaling limit and the resulting error terms. The principal issue is that the shallow water limit and the homogenization process must be performed simultaneously. Our model equations and the error analysis are valid for both the two- and the three-dimensional physical problems.

1. Introduction

Studies of the Euler equations for free surface water waves are important to understanding the dynamics of ocean waves. The case of an idealized flat bottom and the resulting model equations has been widely studied for many years. The more realistic situation of varying bathymetry is less well known, despite its fundamental importance to studies of ocean wave dynamics in coastal regions, and there is not a complete consensus as to the appropriate model equations. In the case of topography there are many asymptotic scaling regimes of interest, including long-wave of modulational hypotheses for the evolution of the free surface, and short scale and/or long scale variations in the variable bottom fluid boundary.

In this paper we address the evolution of waves in the shallow water regime, for which we investigate the effect of the roughness of the bottom topography. The simplest situation is where the bottom varies periodically and rapidly with respect to the typical surface wavelength, a regime which can be described in the context of homogenization theory. Ideally, wave motion in this regime of rapid periodic bottom variations is described in terms of a long wave effective component, which is then adjusted by a smaller multi-scale corrector at the next order of approximation. In terms of the initial value problem for this regime, initial configurations consisting of large scale data with a multi-scale corrector term are expected to give rise to solutions with the same character, up to a smaller error term. In this paper we derive a system of model equations for such multi-scale approximate solutions. While other authors have looked at similar situations, as far as we know this system is new, consisting of a version of the shallow water equations for a mean field or effective components of the surface elevation and the fluid velocity, which then drive a nonlocal system of two additional equations for the evolution of a more rapidly oscillating corrector term. Because of the number of other models that have been proposed to describe this setting, we justify the derivation of our system with a rigorous analysis, giving error estimates for our approximate solutions. In cases in which there is a resonance between the effective velocity and the periodic bottom, the solution of the corrector equation can exhibit secular growth at a linear rate. This phenomenon can be viewed as a nonlinear generalization of the classical Bragg resonance between the bottom topography and the free surface. This is a local phenomenon.

Key words and phrases. Water waves, shallow water, rough bathymetry.
which may occur when the local Froude number is subcritical. In the absence of resonances, our analysis is valid over time intervals of existence of the effective component.

The literature on models of free surface water waves over a variable depth is extensive, including the paper of Miles [21] on its Hamiltonian formulation, and that of Wu [29] on models which are valid in long wave scaling regimes. The paper of Rosales & Papanicolaou [27] studies the long wave regime in which the bottom is rapidly varying, in the sense that the typical wavelength of surface waves is taken to be much longer than typical lengthscale of the variations of the bottom depth. When the latter are periodic, or more generally when they are given by a stationary ergodic process, the techniques of homogenization theory are used to obtain effective long wave model equations. The two most important examples are of periodic bottom topography, and of topography given by a stationary random process. Recently there has been a renewal of interest in this problem, both from the point of view of modeling of water waves in asymptotic scaling regimes, and of mathematical analysis. A central question is the validity of the homogenization approximation, and the character of the resulting model equations. Following [27], the paper of Nachbin & Solna [22] studies the deformation of surface waves by the effects of propagation over a rough bottom, taken in the shallow water scaling regime. In this work the bottom is given by a random process, and the authors treat both the two- and three-dimensional cases. The paper of Craig et al [10] considers large periodic bottom variations, again for dimensions $n = 1 + d$ ($d = 1, 2$), deriving model equations to quite high order of accuracy for the profiles which describe weak limits of surface waves in the homogenization limit of the nonlinear long wave regime. Similarly, the paper of Garnier, Kraenkel & Nachbin [12] studies the long wave scaling limits of water waves over a periodic bottom (for $d = 1$), deriving an effective KdV equation, for which they describe the dependence of the coefficients of nonlinearity and dispersion on the topography of the bottom. This study continues in Garnier, Grajales & Nachbin [13] in the case of random bathymetry. There are other studies of surface wave propagation over periodic bathymetry, that focus on regimes which are not homogenization theoretic. Namely, there is the case in which the typical wavelength of surface waves is comparable or smaller than the typical bottom variations. Among these, Choi & Milewski [6] consider periodic solutions of systems of KdV equations which are coupled through resonant interactions with a periodic bottom. The paper by Nahoulima et al [23] considers shallow water theory with and without dispersive corrections, for a periodic and piecewise constant bottom of very long wavelength.

The paper of Grataloup & Mei [14] considers the propagation of modulational solutions over a random seabed in dimension $d = 1$, which is extended to the case $d = 2$ in Pihl, Mei & Hancock [26]. In this work, the typical wavelengths represented in the surface and the topography are comparable, and the effort is to derive envelope equations for the free surface and to understand its statistical properties, given the ensemble of realizations of the random bathymetry.

There is also a long history of study of resonant interaction between water surface waves with periodic bottom. The paper of Mei [20] gives the theory of linear Bragg resonances between surface waves and bottom variations of the same spatial scale. This is extended to nonlinear resonances in Liu & Yue [19]. The difference between these references and our work is that, in the latter, short scales perturbations of the free surface are generated by interaction of the bottom with long waves on the free surface, a feature typical of homogenization theory.

None of the references above, however, give a mathematical theorem which justifies on a rigorous basis the model equations that are derived. After the derivation of the shallow water model in the present paper, the second main point of our work is to provide a rigorous justification of this derivation. There is a history of results on the mathematical verification of the model equations for free surface water waves, starting in fact with the papers of Ovsjannikov [24, 25] and Kano & Nishida [17] which give existence theorems for the full water wave equations and as well a proof of convergence of solutions in the shallow water scaling limit. In both cases the bottom is assumed to be flat, and the authors work with initial data given in spaces of analytic functions. Results on long wave scaling limits of the water waves problem in dispersive regimes
include Craig [8] and Schneider & Wayne [28] and their treatment of the two-dimensional problem, a long-
time existence theory, and the Boussinesq and KdV limits in Sobolev spaces. More recently, the paper of
Lannes [18] gives an existence theory for solutions of the water wave problem for fluid domains with smooth
variable bathymetry, and the further paper of Alvarez-Samaniego & Lannes [2] gives rigorous results on a
number of long wave scaling limits of the same problem (see also Iguchi [15] and earlier papers of Bona et al [4]
and Chazel[5]), all papers working with Sobolev space initial data. In the context of this body of work, what
distinguishes the present paper is the oscillatory nature of the bottom boundary of the fluid domain, which
has the implications that the solutions themselves are oscillatory, and principally, that the homogenization
theory Ansatz giving the form of solutions must be justified. Our analysis has several features in common
with the results of [11] on the justification of the nonlinear Schrödinger equation and the Davey – Stewar
ton system as envelope equations for modulation theory, the most important of which being that the principal
theorem is a consistency result rather than a full fledged limit theorem for solutions. Nonetheless, as far as
we know this is the first rigorous result which justifies with a rigorous analytic argument the application of
homogenization theory to the water wave problem with rapidly varying periodic bathymetry. In the present
framework, precise error estimates are needed because the shallow water limit and the homogenization limit
do not commute. More precisely, shallow water expansions are derived for slowly varying bottoms, neglecting
some terms that are relevant for rough bottoms. Conversely, homogenization limits are usually performed
with low regularity estimates on solutions, that place them outside of the regime of high order shallow
water asymptotics (see for instance [7] for a recent homogenization result at leading order for the Dirichlet-
Neumann operator). The point of our work and the source of many of its technical difficulties is that we
perform the homogenization and shallow water limit simultaneously, thereby retaining the full complement of
relevant terms from the original water waves equations. The (local) effects of this infinity of terms neglected
in previous studies add up to create the nonlocal effects present in our approximation.

1.1. General setting. The time-dependent fluid domain consists of the fluid domain \( \Omega(b, \zeta) = \{(x, z) \in \mathbb{R}^{d+1}, -H_0 + b(x) < z < \zeta(x, t)\} \) in which the fluid velocity is represented by the gradient of a velocity
potential \( \Phi \). The dependent variable \( \zeta(x, t) \) denotes the surface elevation and \( b(x) \) denotes the variation of
the bottom of the fluid domain from its mean value. We use the Hamiltonian formulation due to Zakharov [30]
and Craig & Sulem [9] in the form of a coupled system for the surface elevation \( \zeta \) and the trace of the velocity
potential at the surface \( \psi = \Phi_{|z=0} \), namely

\[
\begin{align*}
\partial_t \zeta - G[\zeta, b] \psi &= 0, \\
\partial_t \psi + g \zeta + \frac{1}{2} |\nabla \psi|^2 - \frac{(G[\zeta, b] \psi + \nabla \zeta \cdot \nabla \psi)^2}{2(1 + |\nabla \zeta|^2)} &= 0.
\end{align*}
\]

The quantity \( G[\zeta, b] \) is the Dirichlet-Neumann operator, defined by

\[
G[\zeta, b] \psi = \sqrt{1 + |\nabla \zeta|^2} \partial_n \Phi_{|z=\zeta},
\]

where \( \Phi \) is the solution of the elliptic boundary value problem

\[
\begin{align*}
\Delta \Phi + \partial_n^2 \Phi &= 0 \quad \text{in} \quad \Omega(b, \zeta), \\
\Phi_{|z=\zeta} &= \psi, \quad \partial_n \Phi_{|z=-H_0} = 0.
\end{align*}
\]

Writing the equations of evolution in terms of nondimensional variables, different asymptotic regimes of
this problem are identified by scaling regimes of the associated dimensionless parameters. Denote by \( A \)
the typical amplitude of surface waves, with \( \lambda \) their typical wavelength. Similarly let \( B \) denote the typical
amplitude of the variations of the bottom from its mean value \( H_0 \), with \( \ell \) their typical wavelength. From
these quantities we define the dimensionless variables as follows:

\[
\begin{align*}
x &= \lambda X', & z &= H_0 z', & t &= \frac{\lambda}{\sqrt{g H_0}} t', \\
\zeta &= A \zeta', & \Phi &= \frac{1}{\ell^2} \lambda \sqrt{g H_0} \Phi', & b &= B b'(\frac{x}{\lambda}).
\end{align*}
\]
Stemming from this change of variables there are four dimensionless parameters,
\begin{equation}
\mu = \frac{H^2}{\lambda^2}, \quad \epsilon = \frac{A}{H_0}, \quad \beta = \frac{B}{H_0}, \quad \gamma = \frac{\ell}{\lambda}.
\end{equation}

Our analysis is concerned with the shallow water regime $\mu \ll 1$. The relative amplitude of solutions is governed by $\epsilon$. In addition to this, the relative amplitude of the bathymetry is given by $\beta$, the parameter $\gamma$ determines the relative length of bottom perturbations with respect to the typical wavelength of surface waves, and the bottom variations $b'(\cdot)$ are assumed to be $2\pi$-periodic in all variables. We consider relatively large amplitude surface waves, meaning that no smallness assumption is made on $\epsilon$. As usual for this regime, we therefore set $\epsilon = 1$ for the sake of simplicity. With regard to the bottom variations, we set
\begin{equation}
\beta = \sqrt{\mu} = \gamma \ll 1.
\end{equation}

The fact that $\beta = \gamma$ corresponds to small bathymetry slope in this regime, while the roughness strength $\rho := \sqrt{\mu}/\gamma = 1$. For clarity of notation we drop this ‘prime’ notation for the remainder of the paper.

### 1.2. Presentation of results

The first result of this paper is the construction of an approximate solution $(\zeta_a, \psi_a)$ of the water waves problem in the form of the Ansatz
\begin{align}
\zeta_a &= \zeta_0(X,t) + \gamma \zeta_1(X,X/\gamma,t/\gamma) \\
\psi_a &= \psi_0(X,t) + \gamma^2 \psi_1(X,X/\gamma,t/\gamma).
\end{align}

**Remark 1.1.** The factor of $\gamma^2$ in front of the corrector $\psi_1$ is natural; indeed, this yields a $O(\gamma)$ corrector for the velocity, which is the physical relevant quantity.

Setting $V_0 = \nabla \psi_0$ and $h_0 = 1 + \zeta_0$, we show that $(\zeta_0, V_0)$ satisfies the classical shallow water system with flat bottom,
\begin{equation}
\begin{aligned}
\partial_t \zeta_0 + \nabla \cdot (h_0 V_0) &= 0 \\
\partial_t V_0 + \nabla \zeta_0 + (V_0 \cdot \nabla) V_0 &= 0,
\end{aligned}
\end{equation}

while the corrector terms $(\zeta_1, \psi_1)$ satisfy a linear nonlocal coupled system of equations in the fast variables $(\tau = t/\gamma, Y = X/\gamma)$
\begin{equation}
\begin{aligned}
\partial_\tau \zeta_1 + V_0 \cdot \nabla Y \zeta_1 - |D_Y| \tanh(h_0 |D_Y|) \psi_1 \\
&= V_0 \cdot \nabla \text{sech}(h_0 |D_Y|) b \\
\partial_\tau \psi_1 + V_0 \cdot \nabla Y \psi_1 + \zeta_1 &= 0.
\end{aligned}
\end{equation}

In system (1.10), the functions $\zeta_1, \psi_1$ are periodic in the variables $Y$, while the variables $(t, X)$ are to be treated as parameters. The above system represents the linearized water wave equations in a fluid region of depth $h_0$, with a background flow given by the velocity field $V_0$. The source term of the RHS is due to the effect of scattering of the background flow from the variable bottom.

The second result of this paper is a mathematical justification of the derivation of the above system of model equations (1.9)(1.10). Our proof is in the form of a consistency analysis of the Euler equations of free surface water waves, for which we show that the functions $(\zeta_a, \psi_a)$ whose constituents satisfy (1.9)(1.10) are approximate solutions of the Euler equations. They are not in general an exact solution, but they satisfy the equations (1.1) up to an error term $E_a$, and we show that this error is small. Namely, we prove that
\begin{equation}
|E_a|_{H^s} < C \gamma^{3/8},
\end{equation}
where the appropriate norm $|\cdot|_{H^s}$ is defined as $|E_a|_{H^s} = |E_{a1}|_{L^2} + \gamma^{-3/8}|E_{a2}|_{H^{1/2}}$, and $E_a = (E_{a1}, E_{a2})$. In particular, the error is small for the usual Hamiltonian norm of the water waves equations. The most striking point of our analysis is that this result is valid for the natural time scale $t = O(1)$ associated to (1.9).
only if the free surface does not resonate with the rapidly varying bottom. Such a resonance is obtained if there exist \((t,X)\) such that
\[
(k \cdot V_0(X,t))^2 = |k| \tanh(b_0(X,t)|k|)
\]
for some \(k \in \mathbb{Z}\) corresponding to a nonzero mode of the Fourier decomposition of the bottom parametrization \(b\). This condition can be viewed as a nonlinear generalization of the classical Bragg resonance which is obtained when the wavelengths of the free surface and of the bottom are of the same order, while here, the latter is much smaller. In absence of such resonances, it is possible to find \textit{locally stationary} solutions for the corrector terms, that is, solutions to (1.10) that do not depend on the fast time variable \(\tau\). When such resonances occur, the dependence of the correctors on \(\tau\) cannot be removed, and this induces secular growth effects that destroy the accuracy of the approximation (it is only valid on a much smaller time scale, \(t = o(1)\), than the relevant one). It is likely that in this case, the dynamics of the leading term \((\zeta_0, V_0)\) is affected, but this point is left for a future study.

The Ansatz (1.7)(1.8) and the error estimates for the quantity \(E_\alpha\) represent a problem in homogenization theory. The principal terms \((\zeta_0, \psi_0)\) are solutions of an effective equation, and the multiscale terms \((\zeta_1, \psi_1)\) are the first corrector terms. The dynamics of the Euler equations require solving an elliptic equation at each instant of time, on an unknown domain \(\Omega(\gamma, \zeta)\) whose boundaries are defined by oscillatory functions. The approach we take in this paper to the analysis of this elliptic problem and its asymptotic behavior is to transform this domain to a reference domain \(\Omega_0\), resulting in an elliptic problem with rapidly varying periodic coefficients. The principal (effective) term and the correctors are derived from this problem, with the principal term solving an effective equation, and the corrector solving an appropriate cell problem. These are then used to express the Dirichlet – Neumann operator on the free surface of the fluid domain, which in turn is used to express the evolution equations (1.1). The dynamics of the short spatial scales are separated from the evolution of the long scales using the concept of convergence on two scales [1]. The principal part of our mathematical analysis is to control the error estimates of the homogenization approximation (1.7)(1.8) in describing the solutions of this elliptic boundary value problem and the associated expression for the Dirichlet – Neumann problem.

2. \textbf{Euler Equations}

Zakharov showed that the water wave problem can be written in the Hamiltonian form [30]

\[
\partial_t \begin{pmatrix} \zeta \\ \psi \end{pmatrix} = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix} \begin{pmatrix} \delta_\zeta H \\ \delta_\psi H \end{pmatrix},
\]

where the canonical variables are the surface elevation \(\zeta\) and the trace of the velocity potential on the free surface \(\psi = \Phi|_{z=\zeta}\), and the Hamiltonian \(H\) is given by

\[
H(\zeta, \psi) = \frac{1}{2} \int_{\mathbb{R}^d} \psi G[\zeta, b] \psi + g\zeta^2 \, dX.
\]

The system for \((\zeta, \psi)\) is written as (1.1), which in dimensionless form becomes

\[
\begin{cases}
\partial_t \zeta - \frac{1}{\mu} G[\zeta, \beta b] \psi = 0, \\
\partial_t \psi + \zeta + \frac{1}{2} |\nabla \psi|^2 - \mu \frac{\nabla \zeta \cdot \nabla \psi^2}{2(1 + \mu |\nabla \zeta|^2)} = 0,
\end{cases}
\]

where \(b_\gamma(\cdot) = b(\cdot/\gamma)\) and where \(G[\zeta, \beta b]\) is the nondimensionalized Dirichlet – Neumann operator defined by

\[
G[\zeta, \beta b] \psi = \sqrt{1 + |\nabla \zeta|^2} \partial_n \Phi|_{z=\zeta}
\]
and where $\Phi$ is the potential function, satisfying
\begin{equation}
\begin{aligned}
\mu \Delta \Phi + \partial_2^2 \Phi &= 0 \text{ in } \Omega, \\
\Phi_{|_{\xi = \zeta}} &= \psi, \\
\partial_n \Phi_{|_{\xi = -1 + \beta b_\gamma}} &= 0,
\end{aligned}
\end{equation}
in the fluid domain $\Omega(b_\gamma, \zeta)$.

$\Omega(b_\gamma, \zeta) = \{(X, z) \in \mathbb{R}^{d+1}, -1 + \beta b(X/\gamma) < z < \zeta(X)\}.$

The operator $\partial_n$ is the outwards conormal derivative associated with the operator $\mu \Delta + \partial_2^2$. One can rewrite (2.3) in Hamiltonian form (2.1), replacing the Hamiltonian $H$ given by (2.2) by its nondimensional form
\begin{equation}
H(\zeta, \psi) = \frac{1}{2} \int_{\mathbb{R}^d} \left( \psi \frac{1}{\mu} G_{\mu}[\zeta, \beta b_\gamma] \psi + \zeta^2 \right) dX.
\end{equation}

2.1. Notation. We denote by $d = 1$ or 2 the horizontal dimension of the fluid domain, and by $X \in \mathbb{R}^d$ the horizontal variables, while $z$ is the vertical variable. We denote by $e_z$ the unit upward vertical vector.

The domain and the potential function will depend upon both regular and rapidly oscillating variables, which we denote $X \in \mathbb{R}^d$ and $Y \in \mathbb{T}^d = \mathbb{R}^d/(2\pi \mathbb{Z})^d$, respectively. That is, we will give data for the water wave problem which is of a multiscale nature, with the fixed multiscale bottom variations as well, and we will seek solutions which have a well defined asymptotic expansion in terms of multiscale quantities. To express this, we use the classical notation of a multiscale function, namely, a function $f$ we use the classical notation of a multiscale function that is, a function $f = f(X, Y, z)$ is a multiscale function whose realization is the trace $f|_{Y = 0} = f(X, X/\gamma)$. [3]. In the problem we consider, there are other variables as well, such as the vertical variable $z \in [-1, 0]$, for which $f = f(X, Y, Z)$ is a multiscale function defined on $\mathbb{R}^d$ by its nondimensional form (2.2).

The differential operators $\nabla$ and $\Delta$ act on functions of the horizontal variable $X$. The operator $\Lambda$ is defined by $\Lambda := (1 - \Delta)^{1/2}$. We use the standard notation for Fourier multipliers, namely $D = \frac{1}{i} \nabla$ and $\hat{f}(D)u(k) = f(k)\hat{u}(k)$. When applied to multiscale functions, we distinguish this fact using the notation $\nabla_Y$, $\Delta_Y$, $D_Y$, when differential operators act specifically on the fast variables $Y$, and $\nabla_X$, $\Delta_X$, $D_X$ when they act on the long scale $X$ variables. Finally, the notation $\nabla^\mu$ stands for $\nabla^\mu = (\sqrt{\mu} \nabla, \partial_2)^T$.

We encounter functions defined on the fluid domain $\Omega(b_\gamma, \zeta)$ or the reference domain $\Omega_0 = \mathbb{R}^d \times (0, 1)$, as well as functions defined on the free surface, parametrized by $X \in \mathbb{R}^d$. The notation used for function space norms is that $\| \cdot \|_{L^2}$, $\| \cdot \|_{H^m}$ is used for the classical Sobolev space norms over $\Omega_0$, while for norms defined over the boundary $X \in \mathbb{R}^d$ we use the notation $\| \cdot \|_{L^2}$, $\| \cdot \|_{H^m}$. Norms of multiscale functions are given similarly, for example $\| \cdot \|_{L^2(C^r)}$.

For all $r_1, r_2 \geq 0$, we also define the space $H^{r_1, r_2} = H^{r_1, r_2}(\mathbb{R}^d \times \mathbb{T}^d)$ by
\begin{equation}
H^{r_1, r_2}(\mathbb{R}^d \times \mathbb{T}^d) = \{ f \in L^2(\mathbb{R}^d \times \mathbb{T}^d), \| f \|_{H^{r_1, r_2}} < \infty \},
\end{equation}
with $\| f \|_{H^{r_1, r_2}} = \| (1 - \Delta_X)^{r_1/2} (1 - \Delta_Y)^{r_2/2} f \|_{L^2(\mathbb{R}^d \times \mathbb{T}^d)}$.

2.2. Change of variables and domain. The first component of the Hamiltonian (2.6) corresponds to the nondimensionalized kinetic energy. It follows from the definition of $G_{\mu}[\zeta, \beta b_\gamma]$ and Green’s identity that
\begin{equation}
\int_{\mathbb{R}^d} \psi \frac{1}{\mu} G_{\mu}[\zeta, \beta b_\gamma] \psi \, dX = \frac{1}{\mu} \int_{\Omega} |\nabla^\mu \Phi|^2 \, dz \, dX,
\end{equation}
where $\Phi$ is the velocity potential (2.5). Since this expression depends on $\beta$ and $\gamma$ through the domain of integration $\Omega(b_\gamma, \zeta)$, it is convenient to transform it into an integral over a fixed domain independent of the parameters and of the perturbations $\zeta$ and $b$. Under the assumption that the fluid height $h = 1 + \zeta - \beta b_\gamma$ is always non-negative, namely
\begin{equation}
3\alpha > 0, \quad 1 + \zeta - \beta b_\gamma \geq \alpha \text{ on } \mathbb{R}^d.
\end{equation}
an explicit diffeomorphism $S$ mapping the flat strip $\Omega_0$ onto the fluid domain $\Omega$ is given by

$$S : \quad \Omega_0 \rightarrow \Omega \quad \text{where} \quad (X, z) \mapsto (X, z + \sigma(X, z)),$$

where $\sigma(X, z) = (z + 1)\zeta(X) - z\beta\gamma(X)$. We have in particular $h = 1 + \partial_z \sigma$.

Defining $\phi$ on $\Omega_0$ by $\phi = \Phi \circ S$, one can check (see Prop. 2.7 of [18] and §2.2 of [2]) that the new potential function $\phi$ solves

$$\begin{cases}
\nabla^\mu \cdot P[\sigma] \nabla^\mu \phi = 0, \\
\phi_{\mid_{z=0}} = \psi, \\
\partial_n \phi_{\mid_{z=-1}} = 0,
\end{cases}$$

where $\partial_n \phi_{\mid_{z=-1}}$ is the outward conormal derivative in the new variables

$$\partial_n \phi_{\mid_{z=-1}} = -\mathbf{e}_z \cdot P[\sigma] \nabla^\mu \phi_{\mid_{z=-1}},$$

and where the matrix $P[\sigma]$ is given by

$$P[\sigma] = \begin{pmatrix}
\frac{hI}{\sqrt{\mu \nabla} \sigma} & -\frac{\sqrt{\mu \nabla} \sigma}{1 + \mu |\nabla \sigma|^2} \\
-\frac{1}{h} & \frac{1 + \mu |\nabla \sigma|^2}{h}
\end{pmatrix}, \quad \text{with} \quad h = 1 + \zeta - \beta \gamma.$$

### 3. Multiple scale asymptotic expansions

#### 3.1. Ansatz and decomposition of the solutions

This section is devoted to the study of the elliptic problem (2.11) where $(\zeta, \psi)$ are given; the time is fixed and appears as a parameter. We pose the multiscale Ansatz on $(\zeta, \psi)$:

$$(3.1) \quad \begin{align*}
\zeta &= \zeta_0(X) + \gamma \zeta_1(X, X/\gamma) \\
\psi &= \psi_0(X) + \gamma^2 \psi_1(X, X/\gamma).
\end{align*}$$

Recalling that $\beta = \gamma = \sqrt{\mu}$, this leads to the decomposition of the height function of the fluid domain

$$h = h_0 + \beta h_1, \quad \text{where} \quad h_0 = 1 + \zeta_0 \quad \text{and} \quad h_1 = \zeta_1 - b \gamma.$$

Similarly, the new vertical deformations are posed in terms of this Ansatz

$$\sigma = \sigma_0 + \beta \sigma_1, \quad \text{where} \quad \sigma_0 = (z + 1)\zeta_0 \quad \text{and} \quad \sigma_1 = (z + 1)\zeta_1 - z b \gamma.$$

The coefficients $P[\sigma]$ are then written as

$$P[\sigma] = P_0 + \beta P_1,$$

with

$$(3.2) \quad P_0 = P[\sigma_0] \quad \text{and} \quad \beta P_1 = P[\sigma] - P_0.$$

Explicitly

$$P_1 = \begin{pmatrix}
(\zeta_1 - b)I & -\frac{1}{\sqrt{\mu \nabla} \sigma_1} \\
-\frac{1}{\sqrt{\mu \nabla} \sigma_1} & \frac{1 + \mu |\nabla \sigma_1|^2}{h_0}
\end{pmatrix}.$$

We accordingly decompose the potential function $\phi$ as

$$(3.3) \quad \phi = \phi_0(X, z) + \beta \gamma \chi(X, z; \gamma) = \phi_0(X, z) + \mu \chi(X, z; \gamma)$$

where all the contributions coming from the roughness are contained in $\chi$. This section is devoted to deriving asymptotic expansions, with accompanying error estimates on the two components $\phi_0$ and $\chi$, in the limit $\mu \to 0$. In order to do so, we must augment (2.9) with the assumption that

$$(3.4) \quad \exists \alpha_0 > 0, \quad 1 + \zeta_0 \geq \alpha_0 \text{ on } \mathbb{R}^d.$$
Proposition 3.1. Let $\zeta, b \in W^{1,\infty}(\mathbb{R}^d)$ and assume that (2.9) and (3.4) are satisfied. Then for all $\psi$ such that $\nabla \psi \in H^{1/2}(\mathbb{R}^d)$, there exists a unique solution $\phi$ to (2.11) such that $\nabla^\mu \phi \in H^1(\Omega_0)^{d+1}$. Moreover, $\phi_0$ and $\chi$ solve
\[
\begin{cases}
\nabla^\mu \cdot P_0 \nabla^\mu \phi_0 = 0, \\
\phi_0 |_{z=0} = \psi_0, \\
-\nabla_\mathbf{e} \cdot P_0 \nabla^\mu \phi_0 |_{z=-1} = 0,
\end{cases}
\]
and
\[
\begin{cases}
\nabla^\mu \cdot P[\sigma] \nabla^\mu \chi = -\frac{1}{\gamma} \nabla^\mu \cdot P_1 \nabla^\mu \phi_0, \\
\chi |_{z=0} = \psi_1, \\
-\nabla_\mathbf{e} \cdot P[\sigma] \nabla^\mu \chi |_{z=-1} = \frac{1}{\gamma} \nabla_\mathbf{e} \cdot P_1 \nabla^\mu \phi_0 |_{z=-1} .
\end{cases}
\]

Proof. The existence of a unique solution $\phi$ such that $\nabla^\mu \phi \in H^1(\Omega_0)^{d+1}$ to (2.11) is a classical result, and we thus omit the proof. Similarly, there exists a unique solution $\phi_0$ such that $\nabla^\mu \phi_0 \in H^1(\Omega_0)^{d+1}$ to (3.5) since the boundary condition on the lower boundary is the conormal derivative associated to the elliptic operator $\nabla^\mu \cdot P_1 \nabla^\mu$. It remains to prove that $\chi$ solves (3.6). A calculation gives that
\[
\partial_\omega \phi |_{z=-1} = -\nabla_\mathbf{e} \cdot P[\sigma] \nabla^\mu \phi |_{z=-1} = \frac{1}{\gamma} \nabla_\mathbf{e} \cdot P_1 \nabla^\mu \phi |_{z=-1} .
\]
Since by assumption one also has $\partial_\omega \phi |_{z=-1} = 0$ and $-\nabla_\mathbf{e} \cdot P_0 \nabla^\mu \phi |_{z=-1} = 0$, one has
\[
-\nabla_\mathbf{e} \cdot P[\sigma] \nabla^\mu \chi |_{z=-1} = \frac{1}{\gamma} \nabla_\mathbf{e} \cdot P_1 \nabla^\mu \phi |_{z=-1} .
\]
It is straightforward to check that $\chi |_{z=0} = \psi_1$ and that
\[
\nabla^\mu \cdot P[\sigma] \nabla^\mu \chi = \frac{1}{\gamma} \nabla^\mu \cdot P[\sigma] \nabla^\mu \phi - \nabla^\mu \cdot P[\sigma] \nabla^\mu \phi_0
\]
and the result follows. 

3.2. Asymptotic analysis with estimates of $\nabla^\mu \phi_0$. In this section we prove an estimate on $\nabla^\mu \phi_0$, and we give the first terms of its asymptotic expansion in the limit as $\mu \to 0$. For purposes of understanding the $H^{-1/2}$-norm of the trace of $\nabla^\mu \phi_0$ on the free surface $\{z = 0\}$, we use $L^2$ estimates on $\Omega_0$ of both $\nabla^\mu \phi_0$ and its generalized Riesz transform, given by $\nabla^\mu \cdot P_1 \nabla^\mu \phi_0$. This is generalized to higher order norms.

Proposition 3.2. Let $r \in \mathbb{N}$ and $\zeta_0 \in W^{1+r,\infty} \cap W^{2,\infty}(\mathbb{R}^d)$ and assume that (3.4) is satisfied for some $\alpha_0 > 0$. Then

(i.) For all $\mu \in (0,1)$ and all $\psi_0$ such that $\nabla \psi_0 \in H^r(\mathbb{R}^d)$, the solution $\phi_0$ to (3.5) satisfies
\[
\|\nabla^\mu \phi_0\|_{L^2} \leq \mu C(1, \zeta_0) |\psi_0|_{W^{1+r,\infty}} \|\nabla \psi_0\|_{H^r} ,
\]
\[
\|\nabla^{r-1} \partial_\omega \nabla^\mu \phi_0\|_{L^2} \leq \mu C(1, \zeta_0) |\psi_0|_{W^{1+r,\infty}} |\phi_0|_{W^{2,\infty}} \|\nabla \psi_0\|_{H^r} ,
\]

(ii.) If $\nabla \psi_0 \in H^{r+1}(\mathbb{R}^d)$, one also has
\[
\|\nabla^\mu \phi_0 - \nabla^\mu \psi_0\|_{L^2} \leq \mu C(1, \zeta_0) |\psi_0|_{W^{1+r,\infty}} \|\nabla \psi_0\|_{H^{r+1}} ,
\]
\[
\|\nabla^{r-1} \partial_\omega (\nabla^\mu \phi_0 - \nabla^\mu \psi_0)\|_{L^2} \leq \mu C(1, \zeta_0) |\psi_0|_{W^{1+r,\infty}} |\phi_0|_{W^{2,\infty}} \|\nabla \psi_0\|_{H^{r+1}} ,
\]

(iii.) Suppose that $\zeta_0 \in W^{2+r,\infty}(\mathbb{R}^d)$ and $\Delta \psi_0 \in H^{2+r}(\mathbb{R}^d)$, and set
\[
\phi_0^{(1)} = -h_0^2 \left( \frac{2}{z} + z \right) \Delta \psi_0 , \quad (h_0 := 1 + \zeta_0) .
\]
as the next term of the asymptotic expansion. Then there are estimates of the remainder, in the form
\[
\|\Lambda^r (\nabla^\mu \phi_0 - \nabla^\mu (\psi_0 - \mu \phi_0^{(1)}))\|_{L^2} \leq \mu^2 C\left(\frac{1}{\alpha_0}, |\zeta_0|_{W^{2+r,\infty}}\right) |\Delta \psi_0|_{H^{2+r}}; \\
\|\Lambda^{r-1} \partial_2 \nabla^\mu (\phi_0 - \psi_0 - \mu \phi_0^{(1)})\|_{L^2} \leq \mu^2 C\left(\frac{1}{\alpha_0}, |\zeta_0|_{W^{2+r,\infty}}\right) \Delta \psi_0|_{H^{2+r}}.
\]

Proof. The first inequality of the proposition is obtained by standard elliptic estimates for \(\|\nabla^\mu \phi_0\|_{L^2}\) (see Corollary 2.2 of [2]). The Riesz transform of \(\nabla^\mu \phi_0\) has components \(\Lambda^{-1} \partial_2 \nabla^\mu \phi_0 = (\sqrt{\mu} \Lambda^{-1} \nabla \partial_2 \phi_0, \Lambda^{-1} \partial_2 \phi_0)\); estimates of the first component come from the first inequality of (i), since \(\Lambda^{-1} \nabla\) is \(L^2\) bounded. Estimates of the second component are obtained through the equation (3.5) itself. Namely one has an expression for \(\partial_2 \phi_0\) in the form
\[
\partial_2^2 \phi_0 = \mu \frac{h_0}{1 + \mu |\nabla \sigma_0|^2} \left[ - \frac{\partial_2 |\nabla \sigma_0|^2}{h_0} \partial_2 \phi_0 + \partial_2 (\nabla \sigma_0 \cdot \nabla \phi_0) + \nabla \cdot (\nabla \sigma_0 \partial_2 \phi_0) - \nabla \cdot (h_0 \nabla \phi_0) \right].
\]

In order to get an estimate on \(\|\Lambda^{r-1} \partial_2 \phi_0\|_2\), we need the following lemma.

Lemma 3.3. Let \(r \in \mathbb{N}\) and \(F\) and \(G\) \(\geq 0\) be such that \(\Lambda^{r-1} F \in L^2(\Omega_0)\) and \(G \in L^\infty((-1,0); W^{r-1,\infty}(\mathbb{R}^d))\). Then
\[
\|\Lambda^{r-1} (\frac{F}{1+G})\|_{L^2} \leq C\left(\|G\|_{L^\infty W^{r-1,\infty}}\right) \|\Lambda^{r-1} F\|_{L^2}.
\]

Proof. Just write \(\frac{F}{1+G} = F - F \frac{G}{1+G}\). Recalling that one has \(|f|_{H^{r-1}} \lesssim |f|_{H^{r-1}} |g|_{W^{r-1,\infty}}\), we get
\[
\|\Lambda^{r-1} (\frac{F}{1+G})\|_{L^2} \lesssim \|\Lambda^{r-1} F\|_{L^2} (1 + \|\frac{G}{1+G}\|_{L^\infty W^{r-1,\infty}}) \lesssim C\left(\|G\|_{L^\infty W^{r-1,\infty}}\right) \|\Lambda^{r-1} F\|_{L^2}.
\]

Applying this lemma to (3.7) with \(G = \mu |\nabla \sigma_0|^2\), one easily gets
\[
\|\Lambda^{r-1} \partial_2^2 \phi_0\|_{L^2} \leq \mu C\left(\frac{1}{\alpha_0}, |\zeta_0|_{W^{r+1,\infty}}\right) \|\Lambda^{r} \nabla^\mu \phi_0\|_{L^2},
\]
and the estimate follows from the control on \(\|\Lambda^r \nabla^\mu \phi_0\|_{L^2}\) established above.

For the second point of the proposition, we write \(\phi_0 = \psi_0 + \mu \chi_0^{(1)}\). The resulting system for \(\chi_0^{(1)}\) is
\[
\begin{cases}
\nabla^\mu \cdot P_0 \nabla^\mu \chi_0^{(1)} = -\frac{1}{\mu} \nabla^\mu \cdot P_0 \nabla^\mu \psi_0 \\
\chi_0^{(1)}|_{z=0} = 0, \quad -\mathbf{e}_z \cdot P_0 \nabla^\mu \chi_0^{(1)}|_{z=-1} = \frac{1}{\mu} \mathbf{e}_z \cdot P_0 \nabla^\mu \psi_0|_{z=-1}.
\end{cases}
\]

A calculation shows that
\[
-\frac{1}{\mu} \nabla^\mu \cdot P_0 \nabla^\mu \psi_0 = -\nabla \cdot (h_0 \nabla \psi_0) + \partial_z (\nabla \sigma_0 \cdot \nabla \psi_0) = -h_0 \Delta \psi_0
\]
and that \(\mathbf{e}_z \cdot P_0 \nabla^\mu \psi_0|_{z=-1} = 0\), we obtain
\[
\begin{cases}
\nabla^\mu \cdot P_0 \nabla^\mu \chi_0^{(1)} = -h_0 \Delta \psi_0, \\
\chi_0^{(1)}|_{z=0} = 0, \quad -\mathbf{e}_z \cdot P_0 \nabla^\mu \chi_0^{(1)}|_{z=-1} = 0.
\end{cases}
\]

Multiplying the equation by \(\chi_0^{(1)}\) and integrating by parts, we get
\[
\int_{\Omega_0} \nabla^\mu \chi_0^{(1)} \cdot P_0 \nabla^\mu \chi_0^{(1)} \, dzdX = \int_{\Omega_0} \chi_0^{(1)} h_0 \Delta \psi_0 \, dzdX.
\]
Using the coercivity of the matrix \( P_0 \) (Prop. 2.3.iii of [2]), the Cauchy-Schwarz inequality and Poincaré inequality (in order to control \( \| \chi_0^{(1)} \|_{L^2} \) by \( \| \nabla \mu \chi_0^{(1)} \|_{L^2} \)), one gets
\[
\| \nabla \mu \chi_0^{(1)} \|_{L^2} \leq C(\frac{1}{\alpha_0}, |\varphi_0|_{W^{1,\infty}}) |\Delta \psi_0|_{L^2}
\]
and the result follows. Higher order estimates are handled similarly and only require the control of additional commutator estimates. We omit these classical details. The estimate of the generalized Riesz transform \( \Lambda^{-1} \partial_x \nabla \mu (\phi_0 - \psi_0) \) is similar to the analog estimate in (i) of this proposition.

For the third point of the proposition, we solve (3.9) at lowest order in \( \mu \). We write \( \chi_0^{(1)} = \phi_0^{(1)} + \mu \chi_0^{(2)} \), or equivalently
\[
\phi_0 = \psi_0 + \mu \phi_0^{(1)} + \mu^2 \chi_0^{(2)}
\]
with \( \phi_0^{(1)} = -h_0^2(\sqrt{z} + z) \Delta \psi_0 \). The correction \( \chi_0^{(2)} \) satisfies the system
\[
\begin{align*}
\nabla \mu \cdot P_0 \nabla \mu \chi_0^{(2)} &= -\nabla \cdot (h_0 \nabla \phi_0^{(1)} - \nabla \sigma_0 \partial_z \phi_0^{(1)}) + \partial_z (\nabla \sigma_0 \cdot \nabla \phi_0^{(1)} - \frac{\nabla \sigma_0^2}{h_0} \partial_z \phi_0^{(1)}), \\
\chi_0^{(2)}|_{\gamma=0} &= 0, \\
-\mathbf{e}_z \cdot P_0 \nabla \mu \chi_0^{(2)}|_{\gamma=1} &= 0,
\end{align*}
\]
where we used the fact that \( \mathbf{e}_z \cdot P_0 \nabla \mu \phi_0^{(1)}|_{\gamma=1} = 0 \) to obtain the bottom boundary conditions. Proceeding as above, we get the result. \( \square \)

3.3. Asymptotic analysis with estimates of \( \chi \). To find an asymptotic expansion of \( \chi \), our starting point is the equation (3.6) for \( \chi \). Decompose the solution as the sum of a multiscale function and a correction term,
\[
\chi = \phi_1^{(0)}(X, Y, z)|_{Y=\frac{\sqrt{\mu}}{2}} + \sqrt{\mu} \chi_1^{(1)}(X, z; \gamma) .
\]
When acting on a multiscale function of the variables \( (X, X/\gamma) \), the operator \( \nabla \mu \) becomes \( \nabla_{Y,z} + \nabla_X^{\mu} \), where \( \nabla_X = \left( \sqrt{\mu} \nabla_X \right) \):
\[
\nabla \mu (f(X, Y)|_{Y=\frac{\sqrt{\mu}}{2}}) = [(\nabla_{Y,z} + \nabla_X^{\mu}) f(X, Y)]|_{Y=\frac{\sqrt{\mu}}{2}}.
\]
We can therefore write
\[
\nabla \mu \cdot P[\sigma] \nabla \mu \chi = (\nabla_{Y,z} + \nabla_X^{\mu}) \cdot P_0 (\nabla_{Y,z} + \nabla_X^{\mu}) \phi_0^{(1)}|_{Y=\frac{\sqrt{\mu}}{2}} + \beta \nabla \mu \cdot P_1 \nabla \mu \phi_0^{(1)} + \sqrt{\mu} \nabla \mu \cdot P[\sigma] \nabla \mu \chi_1^{(1)},
\]
so that (3.6) becomes (recall that \( \beta = \sqrt{\mu} \))
\[
\begin{align*}
\nabla_{Y,z} \cdot P_0 \nabla_{Y,z} \phi_0^{(1)}|_{Y=\frac{\sqrt{\mu}}{2}} + \sqrt{\mu} \nabla \mu \cdot P[\sigma] \nabla \mu \chi_1^{(1)} \\
&= -\frac{1}{\gamma} \nabla \mu \cdot P_1 \nabla \mu \phi_0 + \sqrt{\mu} \nabla \mu \cdot \tilde{A} + \sqrt{\mu} \tilde{g} , \\
(\phi_0^{(1)}|_{Y=\frac{\sqrt{\mu}}{2}} + \sqrt{\mu} \chi_1^{(1)})|_{\gamma=0} &= \psi_1|_{Y=\frac{\sqrt{\mu}}{2}} , \\
( -\mathbf{e}_z \cdot P_0 \nabla_{Y,z} \phi_1^{(0)}|_{Y=\frac{\sqrt{\mu}}{2}} )|_{\gamma=1} &= -\sqrt{\mu} \mathbf{e}_z \cdot P[\sigma] \nabla \mu \chi_1^{(1)}|_{\gamma=1} , \\
&= \frac{1}{\gamma} \mathbf{e}_z \cdot P_1 \nabla \mu \phi_0|_{\gamma=1} - \sqrt{\mu} \mathbf{e}_z \cdot \tilde{A}|_{\gamma=1}
\end{align*}
\]
Proof.

\[
\gamma \text{ and, using that Lemma 3.4.}
\]

\[
\text{and}
\]

\[
\tilde{g} = - \left( \nabla X_0 \right) \cdot (P_0 \nabla Y_0 \phi_1^{(0)})|_{Y = \tilde{X}}.
\]

In order to make the leading order terms in (3.12) explicit, we further decompose \( P_0 \) as \( P_0 = P_0^{(0)} + \sqrt{\mu} P_0^{(1)} \) and \( P_1 = P_1^{(0)} + \sqrt{\mu} P_1^{(1)} \), with

\[
P_0^{(0)} = \begin{pmatrix} h_0 I & 0 \\ 0 & h_0 I \end{pmatrix}, \quad P_0^{(1)} = \begin{pmatrix} 0 & -\nabla \sigma_0 \sqrt{\frac{1}{\mu}} \\ -\nabla \sigma_0 \sqrt{\frac{1}{\mu}} & h_0 \end{pmatrix}
\]

and

\[
P_1^{(0)} = \begin{pmatrix} (\zeta_1 - b) I & -\nabla Y \sigma_1 \\ -\nabla Y \sigma_1 & h_0 I \end{pmatrix}, \quad P_1^{(1)} = \begin{pmatrix} 0 & -\nabla Y \sigma_1 \\ -\nabla Y \sigma_1 & h_0 \end{pmatrix}
\]

where the \((2,2)\)-coefficient of \( P_1^{(1)} \) is

\[
p_{22}^{(2)} = \mu^{-1/2} \left( \beta^{-1} \left( \frac{1 + \mu |\nabla \sigma|^2}{h} - 1 + \mu |\nabla \sigma_0|^2 \right) - \frac{b - \zeta_1}{h_0} \right).
\]

**Lemma 3.4.** The coefficient matrix \( P_1 = P_1(\sigma) \) has multiscale functions as coefficients. Considered as \( P_1 = P_1(X, X/\sqrt{\mu}) \), the following estimates hold for all \( r \in \mathbb{N} \):

\[
\| P_1^{(0)} \|_{L_{X,Y}^{\infty} W_{r}^{\infty}} + \| \partial_2 P_1^{(0)} \|_{L_{X,Y}^{\infty} W_{r}^{\infty}} \leq \mu^{-r/2} C \left( \frac{1}{\alpha_0}, |\zeta_0| C^{r+1}, |\zeta_1| C^r + |\nabla Y \zeta_1| C^r + |b| C^{r+1} \right),
\]

\[
\| P_1^{(1)} \|_{L_{X,Y}^{\infty} W_{r}^{\infty}} + \| \partial_2 P_1^{(1)} \|_{L_{X,Y}^{\infty} W_{r}^{\infty}} \leq \mu^{-r/2} C \left( \frac{1}{\alpha_0}, \frac{1}{\alpha_3}, |\zeta_0| C^{r+1}, |\zeta_1| C^r, |\nabla X \zeta_1| C^r, |\nabla Y \zeta_1| C^r, |b| C^{r+1} \right).
\]

**Proof.** The proof follows by inspecting the elements of \( P_1 \), \( P_1^{(0)} \) and \( P_1^{(1)} \). \( \square \)

Given the above decompositions of \( P_0 \) and \( P_1 \), the first term of the LHS of (3.12) is

\[
\nabla Y \cdot P_0 \nabla Y \cdot \phi_1^{(0)} = \nabla Y \cdot P_0^{(0)} \nabla Y \cdot \phi_1^{(0)} + \sqrt{\mu} \nabla Y \cdot P_1^{(1)} \nabla Y \cdot \phi_1^{(0)}
\]

and, using that \( \gamma = \sqrt{\mu} \), the first term of the RHS of (3.12) is

\[
\frac{1}{\gamma} \nabla^\mu \cdot P_1 \nabla^\mu \phi_0 = \frac{1}{\gamma} \nabla^\mu \cdot P_0^{(0)} \nabla^\mu \psi_0 + \frac{1}{\gamma} \nabla^\mu \cdot P_1^{(0)} \nabla^\mu (\phi_0 - \psi_0) + \nabla^\mu \cdot P_1^{(1)} \nabla^\mu \phi_0
\]

\[
= \nabla Y \cdot P_1^{(0)} \left( \nabla \psi_0 \right)
\]

and

\[
\left. \nabla Y \cdot P_1^{(1)} \left( \nabla \psi_0 \right) \right|_{Y = \tilde{X}} + \nabla X \cdot P_1^{(0)} \left( \nabla \psi_0 \right) \left. \right|_{Y = \tilde{X}} + \nabla^\mu \cdot P_1^{(1)} \nabla^\mu \phi_0.
\]

Extracting the principal term from these two expressions, we deduce that

\[1\text{The operator } \nabla^\mu \text{ always acts on multiscale functions on the two variables } X \text{ and } z \text{ (and not on } Y). \text{ The notation } \nabla^\mu \phi_1^{(0)} \text{ is therefore a shortcut for } \nabla^\mu (\phi_1^{(0)})|_{Y = \tilde{X}}.]
Assume that variable The cell problem.

\[
\begin{align*}
\nabla_{Y,z} \cdot P_0^{(0)} \nabla_{Y,z} \phi_1^{(0)}|_{Y=\frac{\pi}{2a}} + \sqrt{\mu} \nabla^\mu \cdot P[\sigma] \nabla^\mu \chi_1^{(1)} |_{Y=\frac{\pi}{2a}} &= - \nabla_{Y,z} \cdot P_1^{(0)} \left( \nabla \phi_0 \right) |_{Y=\frac{\pi}{2a}} + \sqrt{\mu} \nabla^\mu \cdot A + \sqrt{\mu} g |_{Y=\frac{\pi}{2a}},
\end{align*}
\]

(3.13)

with

\[
A = \tilde{A} - \frac{1}{\gamma \sqrt{\mu}} P_0^{(0)} \nabla^\mu (\phi_0 - \psi_0) - \frac{1}{\sqrt{\mu}} P_1^{(0)} \nabla^\mu \phi_0 + \left( 2 \nabla \sigma_0 \cdot \nabla \phi_0 - \sqrt{\mu} \frac{\nabla^2 \sigma_0}{\gamma} \partial_x \phi_1^{(0)} \right) e_z
\]

and with

\[
g |_{Y=\frac{\pi}{2a}} = \tilde{g} - \nabla \partial_z \sigma_0 \cdot \nabla Y \phi_0 |_{Y=\frac{\pi}{2a}} - (\nabla X \zeta_1) \cdot \nabla \psi_0 - (\zeta_1 - b) \Delta \psi_0.
\]

In order to solve (3.13), we construct \(\phi_1^{(0)}\) as a solution of a cell problem in the variables \(Y\) and \(z\) (the variable \(X\) being considered a parameter). The resulting solution cancels the higher order terms in (3.13), and we are left with an equation for the corrector \(\chi_1^{(1)}\).

### 3.3.1. The cell problem. We assume that \(b, \zeta_1\) are periodic with respect to the variable \(Y\) and we seek a periodic function \(\phi_1^{(0)}(\cdot, Y, z)\) that solves

\[
\begin{align*}

\nabla_{Y,z} \cdot P_0^{(0)} \nabla_{Y,z} \phi_1^{(0)}(\cdot, Y, z) &= - \nabla_{Y,z} \cdot P_1^{(0)} \left( \nabla \phi_0 \right)(\cdot, Y, z) \\
\phi_1^{(0)} |_{z=0} &= \psi_1; \quad - e_z \cdot P_0^{(0)} \nabla_{Y,z} \phi_1^{(0)} |_{z=1} = e_z \cdot P_1^{(0)} \left( \nabla \phi_0 \right)(\cdot, Y, z) = 0.
\end{align*}
\]

(3.15)

This choice of \(\phi_1^{(0)}\) cancels the higher order terms in (3.13). Taking into account the definition of \(P_0^{(0)}\) and \(P_1^{(0)}\), we can further simplify (3.15) into

\[
\begin{align*}
(h_0^2 \Delta_Y + \partial_z^2) \phi_1^{(0)} |_{Y=\frac{\pi}{2a}} &= 0 \\
\phi_1^{(0)} |_{z=0} &= \psi_1; \quad - \frac{1}{h_0} \partial_z \phi_1^{(0)} |_{z=1} = \nabla_Y b \cdot \nabla \psi_0.
\end{align*}
\]

We recall that the spaces \(H^{r_1, r_2}\) that appear in the statement below are defined in (2.7).

### Proposition 3.5

The solution \(\phi_1^{(0)}\) of the cell problem (3.16) is given in operator notation by the expression

\[
\phi_1^{(0)}(X, Y) = \frac{\cosh(h_0(z + 1)|D_Y|)}{\cosh(h_0|D_Y|)} \psi_1(X, Y) + \frac{\sinh(h_0|D_Y|)}{\cosh(h_0|D_Y|)} \nabla_Y b(Y) \cdot \nabla \psi_0(X).
\]

Assume that \(h_0 = h_0(X) = 1 + \zeta_0\) satisfies the hypotheses (3.4), and let \(r_0 > d/2\) and \(r \in \mathbb{N}\). Then, for all multiindex \(\alpha = (\alpha_1, \alpha_2) \in \mathbb{N}^d \times \mathbb{N}^d\) such that \(|\alpha_1| + |\alpha_2| = r\), one has

\[
\begin{align*}
\| \partial_X^\alpha \partial_Y^2 \nabla_X \phi_1^{(0)} \|_{L^2_{X,Y} L^\infty_z} &\leq C(h_0 |Cr+1|) (|\nabla_X \psi_1|_{H^{r+1, r_0+r_0+1, r_0+1}} + |\nabla_X \psi_1|_{H^{r_0+r_0+r_0+r_0+1}} + |b|_{C^{r+2}} |\nabla \psi_0|_{H^{r+1}}), \\
\| \partial_X^\alpha \partial_Y^2 \nabla_{Y,z} \phi_1^{(0)} \|_{L^2_{X,Y} L^\infty_z} &\leq C(h_0 |C^{r+1}|) (|\nabla_Y \psi_1|_{H^{r+1, r_0+r_0+1, r_0+1}} + |\nabla_Y \psi_1|_{H^{r_0+r_0+r_0+r_0+1}} + |b|_{C^{r+2}} |\nabla \psi_0|_{H^{r+1}}).
\end{align*}
\]

Moreover, derivatives of the multiscale function \(\phi_1^{(0)}|_{Y=\frac{\pi}{2a}}\) are controlled as follows

\[
\| \Lambda^\gamma \nabla^\mu \phi_1^{(0)} \|_{L^2} \leq \mu^{-r/2} C(h_0 |Cr+1|) \times (\mu^{\frac{r}{r_0+1}} |\nabla_X \psi_1|_{H^{r_0+r_0+r_0+r_0+1}} + |\nabla_Y \psi_1|_{H^{r_0+r_0+r_0+r_0+1}} + |b|_{C^{r+2}} |\nabla \psi_0|_{H^{r+1}}),
\]

(3.19)
and if \( r \geq 1 \), the same upper bound holds for \( \frac{1}{\sqrt{\mu}} \| \Lambda^{-1} \partial_x \nabla^\mu \phi^{(0)}_1 \|_{L^2} \).

It is of note that the solution of the cell problem is a multiscale expression that can be differentiated arbitrarily many times with respect to the variables \((X,Y,z)\) without developing singular behavior in the limit as \( \mu \to 0 \).

**Proof.** Decomposing the function \( \phi^{(0)}_1 \) in Fourier modes \( \bar{\phi}^{(0)}_{1k} \) with respect to the \( Y \) variable, we find
\[
\bar{\phi}^{(0)}_{1k} = A_k e^{h_0 z |k|} + B_k e^{-h_0 z |k|}
\]
with coefficients
\[
A_k = \frac{1}{e^{h_0 |k|} + e^{-h_0 |k|}} \left( i \frac{k}{|k|} \nabla \hat{\psi}_0 \hat{u}_k + e^{h_0 |k|} \hat{\bar{\psi}}_{1k} \right)
\]
\[
B_k = \frac{1}{e^{h_0 |k|} + e^{-h_0 |k|}} \left( -i \frac{k}{|k|} \nabla \hat{\psi}_0 \hat{u}_k + e^{-h_0 |k|} \hat{\bar{\psi}}_{1k} \right).
\]
After substitution, the solution \( \phi^{(0)}_1 \) is written using operator notation as in the statement (3.17) of the proposition.

For the proof of the estimates of the derivatives of \( \phi^{(0)}_1 (X,Y,z) \), the expression (3.17) is conveniently written in operator notation as
\[
C_1(h_0,z,D_Y) \psi_1(X,Y) + C_2(h_0,z,D_Y) b(Y) \cdot \nabla \psi_0(X),
\]
where the components are
\[
C_1(h_0,z,D_Y) = \frac{\cosh(h_0(z + 1)|D_Y|)}{\cosh(h_0|D_Y|)}, \quad C_2(h_0,z,D_Y) = \frac{\sinh(h_0z|D_Y|)}{\cosh(h_0|D_Y|)} \frac{\nabla Y}{|\nabla Y|}.
\]
For the first term, we remark that the Sobolev embedding \( H^0_Y \subset L^\infty_Y \) yields
\[
\| \partial_X^\alpha \partial_Y^\beta \sum_{\alpha_1 + \alpha_2 = \alpha} C_1(h_0,z,D_Y) \psi_1 \|_{L^2_X L^\infty_Y} \lesssim \int \left[ \sup_z (\| \partial_X^\alpha \partial_Y^\beta \sum_{\alpha_1 + \alpha_2 = \alpha} C_1 \psi_1(X,\cdot,z) \|_{H^\infty_Y}) \right]^2 dX, \quad (k = 0, 1)
\]
where \( \sum \) stands for \( \nabla_X \) and \( \sum \) for \( \nabla_{Y,z} \).

Now, by Plancherel formula (with respect to \( Y \)), one easily checks that
\[
\sup_z (\| \partial_X^\alpha \partial_Y^\beta \nabla_X \psi_1 \|_{H^\infty_Y}) \lesssim C(h_0 |H^{r+1}) \left( \sum_{\beta \leq \alpha} \| \partial_X^\beta \nabla_X \psi_1 \|_{H^{2r+1}} + \| \nabla_Y \psi_1 \|_{H^{r+1}} \right),
\]
\[
\sup_z (\| \partial_X^\alpha \partial_Y^\beta \nabla_Y \psi_1 \|_{H^\infty_Y}) \lesssim C(h_0 |H^{r+1}) \sum_{\beta \leq \alpha} \| \partial_X^\beta \nabla_Y \psi_1 \|_{H^{2r+1}}.
\]
Plugging these inequalities into the integral above then yields the desired result,
\[
\| \partial_X^\alpha \partial_Y^\beta \nabla_X C_1(h_0,z,D_Y) \psi_1 \|_{L^2_X L^\infty_Y} \lesssim C(h_0 |C^{r+1}) \left( \| \nabla_X \psi_1 \|_{H^{2r+1}} + \| \nabla_Y \psi_1 \|_{H^{r+1}} \right),
\]
\[
\| \partial_X^\alpha \partial_Y^\beta \nabla_{Y,z} C_1(h_0,z,D_Y) \psi_1 \|_{L^2_X L^\infty_{Y,z}} \lesssim C(h_0 |C^{r+1}) \left( \| \nabla_Y \psi_1 \|_{H^{2r+1}} + \| \nabla_Y \psi_1 \|_{H^{r+1}} \right).
\]
For the control of the derivatives of \( C_2(h_0,z,D_Y) b(Y) \cdot \nabla \psi_0 \), we easily get that
\[
\| \partial_X^\alpha \partial_Y^\beta \nabla_{X,Y,z} C_2(h_0,z,D_Y) b(Y) \cdot \nabla \psi_0 \|_{L^2_X L^\infty_{Y,z}} \lesssim C(h_0 |C^{r+1}) \| b \|_{C^{r+2}} \| \nabla \psi_0 \|_{H^{r+1}},
\]
where we have (somewhat non-optimally) estimated the action of singular integral operators on \( L^\infty_Y \) at the cost of one derivative. This ends the proof of (3.18).

For the proof of (3.19), we remark that the l.h.s. can be controlled as
\[
\| \Lambda^\mu \nabla^\nu (\phi^{(0)}_1 \big|_{Y = \mathbb{R}}) \|_{L^2} \lesssim \sum_{\alpha_1, \alpha_2} \mu^{-\frac{\alpha_2}{2}} \| \partial_X^\alpha \partial_Y^\beta (\nabla_{Y,z} + \nabla_X^\mu) \phi^{(0)}_1 \|_{L^2_X L^\infty_{Y,z}},
\]
where the summation is over \((\alpha^1, \alpha^2) \in \mathbb{N} \times \mathbb{N}\) such that \(|\alpha^1| + |\alpha^2| \leq r\). The result follows therefore from (3.18) and a straightforward interpolation between the lowest and highest terms in terms of \(\mu\). In order to prove that the same bound holds for \(\chi^{(1)}_\Lambda\), integrating by parts yields

\[ \int_{\Omega_0} P[\sigma]\nabla^\mu \chi^{(1)}_\Lambda \cdot dx = \int_{\Omega_0} A \cdot \nabla^\mu \chi^{(1)}_\Lambda \cdot dx - \int_{\Omega_0} g \chi^{(1)}_\Lambda \cdot dx. \]

The method follows the recipe of classical energy estimates, paying attention to the rapidly oscillating coefficients and their commutators with differential operators. Indeed multiplying (3.20) by \(\chi^{(1)}_\Lambda\) and integrating by parts yields

\[ \int_{\Omega_0} P[\sigma]\nabla^\mu \chi^{(1)}_\Lambda \cdot dx = \int_{\Omega_0} A \cdot \nabla^\mu \chi^{(1)}_\Lambda \cdot dx - \int_{\Omega_0} g \chi^{(1)}_\Lambda \cdot dx. \]

with \(M_0\) as in the statement of the proposition.

For the general case \(r \in \mathbb{N}\), the procedure is exactly the same replacing \(g\) by \(\Lambda^r g\) and \(A\) by \(A^{(r)}\), with

\[ A^{(r)} = \Lambda^r A - [\Lambda^r, P[\sigma]]\nabla^\mu \chi^{(1)}_\Lambda; \]

in particular, it follows from classical commutator estimates and Lemma 3.4 that

\[ \|A^{(r)}\|_{L^2} \leq \|\Lambda^r A\|_{L^2} + C \sum_{k=1}^r \mu^{-k/2} \|\Lambda^{r-k}\nabla^\mu \chi^{(1)}_\Lambda\|_{L^2} \]

so that (3.21) yields in this configuration

\[ \|\Lambda^r \nabla^\mu \chi^{(1)}_\Lambda\|_{L^2} \leq M_0 \left( \|\Lambda^r A\|_{L^2} + \|\Lambda^r g\|_{L^2} \right) + M_r \sum_{k=1}^r \mu^{-k/2} \|\Lambda^{r-k}\nabla^\mu \chi^{(1)}_\Lambda\|_{L^2}. \]

We therefore need the following lemma.
Lemma 3.7. The following estimate holds,
\[ \| \Lambda^r A \|_{L^2} + \| \Lambda^r g \|_2 \leq \mu^{-r/2} M_r \left( | \nabla \psi_0 |_{H^{r+1}} + \mu^{r/2} (| \nabla X \psi_1 |_{H^{r+1+\gamma_0}} + | \nabla X \psi_1 |_{H^{1+\gamma_0}}) \right) \]
Proof. - Control of \( \| \Lambda^r A \|_{L^2} \). Recall that
\[ A = -P_1 \nabla \mu \phi_1^{(0)} - \frac{1}{\mu} P_1^{(1)} \nabla \phi_0 - \frac{1}{\sqrt{\mu}} P_1^{(1)} \nabla \phi_0 \]
(3.23)
\[ = -P_0 \left( \nabla \phi_1^{(0)} \right) \mid_{Y=\phi} + (2 \nabla \sigma_0 \cdot \nabla \phi_1^{(0)} - \sqrt{\mu} \nabla \phi_0^{(0)} |_{Y=\phi} \). \]

A direct application of the chain rule gives
\[ \| \Lambda^r A \|_{L^2} \leq \sum_{k=0}^r \left[ \| P_1 \|_{L^\infty W^{r,\infty}} \| \Lambda^{-k} \nabla \phi_1^{(0)} \|_{L^2} + \| P_1^{(1)} \|_{L^\infty W^{r,\infty}} \| \frac{1}{\sqrt{\mu}} \Lambda^{-k} \nabla \phi_0 \|_{L^2} \right] \]
(3.24)
\[ + \| P_0 \|_{L^\infty W^{r,\infty}} \| \Lambda^r \nabla X \phi_1^{(0)} \|_{L^2} + C(| \zeta_0 |_{C^{r+1}}, \frac{1}{\sigma_0}) \| \Lambda^r \nabla Y \phi_1^{(0)} \|_{L^2}. \]

Using (2.12) and Lemma 3.4 to control the norms of \( P_0 \) and \( P_1 \), and Proposition 3.2 to control the second and third terms in the above expression, we find
\[ \| \Lambda^r A \|_{L^2} \leq M_r \left( | \nabla \psi_0 |_{H^{r+1}} + \mu^{r/2} | \nabla X \psi_1 |_{H^{r+\gamma_0}} + | \nabla X \psi_1 |_{H^{1+\gamma_0}} \right) \]

We now control \( \| \Lambda^{-k} \nabla \phi_1^{(0)} \|_{L^2} \) through (3.19), while \( \| \Lambda^r \nabla X \phi_1^{(0)} \|_{L^2} \) and \( \| \Lambda^r \nabla Y \phi_1^{(0)} \|_{L^2} \) can be controlled using (3.18) and proceeding as in the proof of (3.19). This yields
\[ \| \Lambda^r A \|_{L^2} \leq \mu^{-r/2} M_r \left( | \nabla \psi_0 |_{H^{r+1}} + \mu^{r/2} | \nabla X \psi_1 |_{H^{r+\gamma_0}} + | \nabla X \psi_1 |_{H^{1+\gamma_0}} \right) \]
- Control of \( \| \Lambda^r g \|_{L^2} \). We first recall that
\[ g = - \left( \nabla X \right) \mid_{Y=\phi} + \left( - \nabla \sigma_0 \cdot \nabla \phi_1^{(0)} - \nabla X \phi_1^{(0)} - (\gamma_0 - b) \Delta \psi_0 \right) \mid_{Y=\phi} \]

We get therefore
\[ \| \Lambda^r g \|_{L^2} \leq \mu^{-r/2} M_r \left( | \nabla \psi_0 |_{H^{r+1}} + \mu^{r/2} | \nabla Y \psi_1 |_{H^{r+\gamma_0}} + | \nabla Y \psi_1 |_{H^{1+\gamma_0}} \right) \]

Using (3.22) and the lemma, we get directly
\[ \mu^{-r/2} \| \Lambda^r \nabla \phi_1^{(0)} \|_{L^2} \leq M_r \left( | \nabla \psi_0 |_{H^{r+1}} + \mu^{r/2} | \nabla X \psi_1 |_{H^{r+\gamma_0}} + | \nabla X \psi_1 |_{H^{1+\gamma_0}} \right) \]
\[ + M_r \sum_{k=1}^{r} \mu^{-k/2} \| \Lambda^{-k} \nabla \phi_1^{(0)} \|_{L^2}, \]
and the estimate on \( \| \Lambda^r \nabla \phi_1^{(0)} \|_{L^2} \) follows from a straightforward induction. We now turn to prove the estimate on \( \| \Lambda^r \nabla \phi_0 \|_{L^2} \). As for the control of \( \Lambda^r \nabla \phi_0 \) in Proposition 3.2, it is enough to get an upper bound
on $\| \Lambda^{-1} \partial_x^2 \chi_1 \|$.

The idea is to proceed as in Proposition 3.2, using the equation to get $\partial_x^2 \chi_1$ in terms of
quantities under control,

$$\partial_x^2 \chi_1 = \frac{h}{1 + \mu |\nabla \sigma|^2} \left[ \mu \left( -\frac{\partial}{h} |\nabla \sigma|^2 \partial_x \chi_1 + \partial_x (\nabla \sigma \cdot \nabla \chi_1) + \nabla \cdot (\nabla \sigma \partial_x \chi_1) - \nabla \cdot (h \nabla \chi_1) + \text{RHS} \right) \right];$$

the presence of the fast scale $X/\sqrt{\mu}$ makes things a little more complicated than in the proof of Proposition 3.2, and we need product estimates and a refinement of Lemma 3.3 for multiscale functions.

**Lemma 3.8.** Let $r \in \mathbb{N}$, and denote $(r-1)_+ = \max\{r-1,0\}$. Let also $G = G(X,Y,z) \in L^\infty_x W^{(r-1)+,\infty}_{X,Y}$, and $F \in L^2(\Omega_0)$ be such that $\Lambda^{(r-1)+} F \in L^2(\Omega_0)$. Then

$$\| \Lambda^{-r} (\partial_x^2 \chi_1) \|_{L^2} \lesssim \| F \|_{L^2} \| \Lambda^{(r-1)+} \|_{L^2}.$$

If moreover $G \geq 0$, then

$$\| \Lambda^{-r} \frac{F}{1 + G} \|_{L^2} \lesssim C \left( \| G \|_{L^2} \| \Lambda^{(r-1)+} \|_{L^2} \right)$$

**Proof.** The product estimates are a straightforward consequence of the chain rule; the second pair of estimates is derived as in Lemma 3.3 using these product estimates.

Using Lemma 3.8 and the above expression for $\partial_x^2 \chi_1$, we get, with $\tilde{r} = (r-1)_+ + 1$,

$$(3.25) \quad \| \Lambda^{-1} \partial_x^2 \chi_1 \|_{L^2} \leq M_r \sum_{k=0}^{(r-1)_+} \mu^{-k/2} \| \Lambda^{\tilde{r}-k} \nabla_x \chi_1 \|_{L^2} + \| \Lambda^{(r-1)+-k} \text{RHS} \|_{L^2}.$$
3.4. Asymptotic expansion of the Dirichlet-Neumann operator with estimates. We study here the asymptotic behavior of the Dirichlet-Neumann operator,

\[(3.27)\quad G[\zeta, \beta b_\gamma] \psi = e_z \cdot P[\sigma] \nabla^\mu \phi \big|_{z=0},\]

where \(\phi\) solves (2.11). In the previous section, we have shown that when the surface parametrization \(\zeta\) and the trace of the potential at the surface \(\psi\) are of the form (3.1), one can decompose \(\phi\) into

\[\phi = \phi_0 + \mu \chi,\]

where \(\phi_0\) is deduced from (2.11) by neglecting all the contributions due to the roughness. We have further decomposed \(\phi_0\) and the residual \(\chi\) (which contains all the roughness effects) as

\[
\phi_0 = \psi_0 + \mu \phi_0^{(1)} + \mu^2 \chi_0^{(2)} \quad \text{and} \quad \chi = \chi_1^{(0)} + \sqrt{\mu} \chi_0^{(1)},
\]

with controls on the residuals \(\chi_0^{(2)}\) and \(\chi_1^{(1)}\) given in Propositions 3.2 and 3.6 respectively. We can therefore rewrite \(\phi\) as the sum of an effective part and a residual part,

\[\phi = \phi_{\text{eff}} + \mu^{3/2} \phi_{\text{res}}\]

with

\[\phi_{\text{eff}} = \psi_0 + \mu (\phi_0^{(1)} + \phi_1^{(0)}) \quad \text{and} \quad \phi_{\text{res}} = \chi_1^{(1)} + \sqrt{\mu} \chi_0^{(2)}.\]

Similarly, we decompose the Dirichlet-Neumann operator into an effective and residual part as follows:

**Proposition 3.10.** We separate the expression for the Dirichlet-Neumann operator as

\[G[\zeta, \beta b_\gamma] \psi = (G \psi)_{\text{eff}} + \mu^{3/2} (G \psi)_{\text{res}}\]

where

\[
\frac{1}{\mu} (G \psi)_{\text{eff}} = - \nabla \cdot (h_0 \nabla \psi_0) - \nabla_Y \psi_{\gamma 1} |_{Y=\zeta} \cdot \nabla \psi_0
+ |D_Y| \tanh(h_0 |D_Y|) \psi_{\gamma 1} (X, Y) |_{Y=\zeta} - \nabla \psi_0 \cdot \nabla_Y (\text{sech}(h_0 |D_Y| b)) |_{Y=\zeta}.
\]

The remainder \((G \psi)_{\text{res}}\) satisfies the estimate (r integer),

\[(3.28)\quad |(G \psi)_{\text{res}}|_{H^r} \leq M_\mu r^{-r/2-1/8} \left( |\nabla \psi_0|_{H^{r+1}} + \mu^{r/2} |\nabla_X \psi_1|_{H^{r+1-r_0}} + |\nabla_X Y \psi_1|_{H^{r-r_0+r}} \right)
\]

**Remark 3.11.** The nonlocal operators in the expression for \((G \psi)_{\text{eff}}\) arise from the simultaneous homogenization process and shallow water limit. Homogenization analysis on a shallow water expansion would give a different result. The reason for this difference is that certain terms neglected in standard shallow water expansions are not negligible in the presence of rapidly varying bathymetry; their effects are described in the nonlocal terms of \((G \psi)_{\text{eff}}\).

**Proof.** Recalling that \(P[\sigma] = P_0^{(0)} + \sqrt{\mu} (P_0^{(1)} + P_1)\), with \(P_1 = P_1^{(0)} + \sqrt{\mu} P_1^{(1)}\), one has

\[
G[\zeta, \beta b_\gamma] \psi = e_z \cdot P_0^{(0)} \nabla^\mu \phi_{\text{eff}} |_{z=0} + \sqrt{\mu} e_z \cdot (P_0^{(1)} + P_1) \nabla^\mu \phi_{\text{eff}} |_{z=0}
+ \mu^{3/2} e_z \cdot P[\sigma] \nabla^\mu \phi_{\text{res}} |_{z=0}
= e_z \cdot P_0^{(0)} \nabla^\mu \phi_{\text{eff}} |_{z=0} + \sqrt{\mu} e_z \cdot (P_0^{(1)} + P_1^{(0)}) \nabla^\mu \psi_0 |_{z=0} + \mu e_z \cdot P_1^{(1)} \nabla^\mu \psi_0 |_{z=0}
+ \mu^{3/2} e_z \cdot (P_0^{(1)} + P_1) \nabla^\mu (\phi_0^{(1)} + \phi_1^{(0)}) |_{z=0}
+ \mu^{3/2} e_z \cdot P[\sigma] \nabla^\mu \phi_{\text{res}} |_{z=0}.
\]

We now decompose

\[G[\zeta, \beta b_\gamma] \psi = (G \psi)_{\text{eff}} + \mu^{3/2} (G \psi)_{\text{res}}.\]
with
\[(G\psi)_{\text{eff}} = e_x \cdot P_0(0) \nabla^\mu \phi_{\text{eff}}|_{t=0} + \sqrt{\mu} e_x \cdot (P_0(1) + P_1(0)) \nabla^\mu \psi_0|_{t=0}, \]
\[(G\psi)_{\text{res}} = \frac{1}{\sqrt{\mu}} e_x \cdot P_1(1) \nabla^\mu \psi_0|_{t=0} + e_x \cdot (P_0(1) + P_1) \nabla^\mu (\phi_0(1) + \phi_1(0))|_{t=0} + e_x \cdot P_1[\nabla^\mu \phi_{\text{res}}]|_{t=0}. \]  

(3.29)

The two tasks of this proposition are to give an expression for \((G\psi)_{\text{eff}}\) and to prove an estimate for \((G\psi)_{\text{res}}\).

- **Explicit computation of \((G\psi)_{\text{eff}}\).** From the definition of \(\phi_{\text{eff}}\), we have

\[
\frac{1}{\mu} (G\psi)_{\text{eff}} = e_x \cdot (P_0 + \sqrt{\mu}) \nabla^\mu \psi_0|_{t=0} + e_x \cdot P_1(0) \nabla^\mu \phi_0(1)|_{t=0} + e_x \cdot P_0(0) \nabla^\mu \phi_1(0)|_{t=0} - \nabla \cdot (h_0 \nabla \psi_0) - \nabla \cdot \nabla Y - \frac{1}{h_0} \partial_z \phi_1(0)|_{t=0} .
\]

(3.30)

Computing the last term in the RHS with the help of Proposition 3.5, we get

\[
\frac{1}{h_0} \partial_z \phi_1(0)|_{t=0} = \left| D_Y \tanh(h_0|D_Y|) \psi(X,Y)|_{Y = \infty} + \nabla \psi_0 \cdot \nabla Y (\text{sech}(h_0|D_Y|)b)|_{Y = \infty}, \right.
\]

so that \(G_{\text{eff}}\) is indeed given by the expression stated in the proposition.

- **Control of the residual \((G\psi)_{\text{res}}\).** From the explicit expression (3.29) of \((G\psi)_{\text{res}}\) and Proposition 3.2 and 3.5 and Lemma 3.4, we get

\[
|\langle \langle G\psi \rangle \rangle_{\text{res}}|_{\dot{H}^r} \leq \mu^{-r/2} M_r \left( |\nabla \psi_0|_{\dot{H}^{r+1}} + \mu^{r/2} |\nabla X,Y \psi_1|_{H^{r+1},r_0} + |\nabla X,Y \psi_1|_{H^{1+r_0}} \right)
\]

\[
+ M_r \sum_{k=0}^r \mu^{-k/2} \left| \Lambda^{r-k} \nabla^\mu \phi_{\text{res}} \right|_{t=0} |L^2| ,
\]

which motivates the following lemma.

**Lemma 3.12.**

\[
|\nabla^\mu \phi_{\text{res}}|_{t=0} |L^2| \leq \mu^{-1/8} M_1 \left( |\nabla \psi_0|_{\dot{H}^2} + \mu^{1/2} |\nabla X,Y \psi_1|_{H^{2,r_0}} + |\nabla X,Y \psi_1|_{H^{1+r_0}} \right)
\]

**Proof.** We write

\[
|\nabla^\mu \phi_{\text{res}}|_{t=0} |L^2| \lesssim \mu^{1/8} |\nabla^\mu \phi_{\text{res}}|_{t=0} |H^{1/2}| + \mu^{-1/8} |\nabla^\mu \phi_{\text{res}}|_{t=0} |H^{-1/2}|
\]

\[
\lesssim \mu^{1/8} \left( \mu^{1/4} |\Lambda \nabla^\mu \phi_{\text{res}}|_{L^2} + \mu^{-1/4} \| \partial_z \nabla^\mu \phi_{\text{res}} \|_{L^2} \right) + \mu^{-1/8} \left( \| \nabla^\mu \phi_{\text{res}} \|_{L^2} + \| \Lambda^{-1/2} \partial_z \nabla^\mu \phi_{\text{res}} \|_{L^2} \right).
\]

where, for the second inequality, we have used two different versions of the trace lemma, namely, \( |F|_{t=0} |L^2| \lesssim \mu^{1/4} |\Lambda^{1/2} F|_{L^2} + \mu^{-1/4} \| \Lambda^{-1/2} \partial_z F \|_{L^2} \) and \( |F|_{t=0} |L^2| \lesssim \| \Lambda^{1/2} F \|_{L^2} + \| \Lambda^{-1/2} \partial_z F \|_{L^2} \). The estimate follows therefore from the definition of \(\phi_{\text{res}}\) and Proposition 3.6. \(\square\)

Bound for \(|\Lambda^{-k} \nabla^\mu \phi_{\text{res}}|_{t=0} |L^2|\) are obtained in the same manner, giving rise to a power of \(\mu\) in the form \(\mu^{1-8(r-k)/2}\). \(\square\)

Later in the consistency analysis, we will need an estimate of \(|\langle \langle G\psi \rangle \rangle_{\text{res}}|_{\dot{H}^{r/2}}\). For this purpose, interpolating between \(H^{r-1}\) and \(H^r\), we have \((r \geq 1)\):

\[
|\langle \langle G\psi \rangle \rangle_{\text{res}}|_{H^{r-\frac{1}{2}}} \leq \mu^{1/4} |\langle \langle G\psi \rangle \rangle_{\text{res}}|_{H^r} + \mu^{-1/4} |\langle \langle G\psi \rangle \rangle_{\text{res}}|_{H^{r-1}}
\]

\[
\leq M_r \mu^{r-1/2-1/8} \left( |\nabla \psi_0|_{\dot{H}^{r+1}} + \mu^{r/2} |\nabla X,Y \psi_1|_{H^{r+1},r_0} + |\nabla X,Y \psi_1|_{H^{1+r_0}} \right)
\]  

(3.31)
4. Homogenization with estimates of the equations for water waves

Up to this point the canonical variables of the water wave problem \((\zeta, \psi)\) have been treated as data for an elliptic partial differential equation in a fixed domain. We now return to study the dynamics of the water waves system \((2.3)\) as a time dependent problem. We first derive the effective PDEs satisfied by \((\zeta_0, \psi_0)\) and \((\zeta_1, \psi_1)\), after which we investigate the precision of our approximate solution \((3.1)\) in satisfying the full water wave equation.

4.1. Effective equations. Consider the decomposition \((1.7)(1.8)\) to be an Ansatz for the full Euler equations \((2.3)\), for which the slow and fast scale variables are identified through \(\zeta\) and \(\psi\). Substituting these expressions into the full equations and using the rigorous expansion \((3.30)\), for the first component of equations \((2.3)\) we obtain an equation for the quantity \((\zeta, \psi)\) = \((\zeta_0 + \sqrt{\mu}_1, \psi_0 + \mu \psi_1)\):

\[
\partial_t \zeta_0 + \partial_t \zeta_1 + h_0 \Delta \psi_0 + \nabla \zeta_0 \cdot \nabla \psi_0 + \nabla Y \zeta_1 \cdot \nabla \psi_0
\]

\[
-|D_Y| \tanh(h_0|D_Y|) \psi_0(X, Y)_{Y \rightarrow -} - \nabla \psi_0 \cdot \nabla Y (\sech(h_0|D_Y|)h_1)_{Y \rightarrow -} = -\sqrt{\mu} \partial_t \zeta_1 + \sqrt{\mu}(G\psi_1)_{res}.
\]

At this point the fast and slow time scales are identified, \(Y = X/\sqrt{\mu}\) and \(\tau = t/\sqrt{\mu}\), and we have made no approximation. Similarly, for the second equation of \((2.3)\) we obtain

\[
\partial_t \psi_0 + \sqrt{\mu} \partial_t \psi_1 + \mu \partial_t \psi_1 + \zeta_0 + \sqrt{\mu} \zeta_1 + \frac{1}{2} |\nabla \psi_0 + \sqrt{\mu} (\nabla Y + \sqrt{\mu} \nabla X) \psi_1|^2
\]

\[
= \mu \left( \left( \frac{1}{2} (G\psi_0)_{eff} + \mu^{3/2}(G\psi_0)_{res} \right) + (\nabla \psi_0 + \nabla Y \zeta_1 + \sqrt{\mu} \nabla X \zeta_1) \cdot (\nabla \psi_0 + \sqrt{\mu} \nabla Y \psi_1 + \mu \nabla X \psi_1) \right)^2
\]

\[
2(1 + \mu |\nabla \psi_0 + (\nabla Y + \sqrt{\mu} \nabla X) \psi_1|^2).
\]

Isolating the error terms in \((4.2)\) onto the RHS, one obtains

\[
\partial_t \psi_0 + \sqrt{\mu} \partial_t \psi_1 + \zeta_0 + \sqrt{\mu} \zeta_1 + \frac{1}{2} |\nabla \psi_0|^2 + \sqrt{\mu} |\nabla \psi_0| \cdot \nabla Y \psi_1
\]

\[
= -\mu \partial_t \psi_1 - \mu \nabla \psi_0 \cdot \nabla X \psi_1 - \frac{1}{2} \mu |\nabla Y \psi_1 + \sqrt{\mu} \nabla X \psi_1|^2
\]

\[
+ \mu \left( \left( \frac{1}{2} (G\psi_0)_{eff} + \mu^{3/2}(G\psi_0)_{res} \right) + (\nabla \psi_0 + \nabla Y \zeta_1 + \sqrt{\mu} \nabla X \zeta_1) \cdot (\nabla \psi_0 + \sqrt{\mu} \nabla Y \psi_1 + \mu \nabla X \psi_1) \right)^2
\]

\[
2(1 + \mu |\nabla \psi_0 + (\nabla Y + \sqrt{\mu} \nabla X) \psi_1|^2).
\]

The bottom profile \(b\) is function of the fast variables \(Y = X/\sqrt{\mu}\).

Now adopt the point of view that we seek multi-scale approximations to the system of equations \((4.1)(4.3)\). To impose this scaling regime, make the assumption that the variables \(t, X, \tau, Y\) are independent, so that \((\zeta_0 + \sqrt{\mu} \zeta_1, \psi_0 + \mu \psi_1)\) are multiscale functions of the variables \((t, X, \tau, Y)\). In these equations, \(\zeta_0\) and \(\psi_0\) are functions of \(X, t\) only, while \(\zeta_1\) and \(\psi_1\) are multi-scale functions of both time and space. The original variables will be re-imposed when we return to the identification \(Y = X/\sqrt{\mu}\) and \(\tau = t/\sqrt{\mu}\). In order to justify this otherwise formal separation of slow and fast scales, we will use results on scale separation that appear in [3][10].

Equations \((4.1)(4.2)\) are two equations for the four unknown quantities \((\zeta_0, \zeta_1, \psi_0, \psi_1)\). In order to obtain well defined evolution equations for them, one must identify dynamics that take place on the slow and fast space and time scales. This is performed using the following scale separation lemmas, in which the underlying periodic nature of the cell problem plays a role.

**Proposition 4.1.** Let \(g\) be a continuous function on \(\mathbb{R}^d\) which is periodic over \(\mathbb{T}^d\), and denote \(\tilde{g} = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^d} g(Y) dY\) its average value on \(\mathbb{T}^d\). For any function \(f(X)\) in the Schwarz space \(S(\mathbb{R}^d)\), we have

\[
\int_{\mathbb{T}^d} g(X/\gamma) f(X) dX = \tilde{g} \int_{\mathbb{T}^d} f(X) dX + O(\gamma^N),
\]

where \(N\) is a non-negative integer.
for any $N$.

**Proposition 4.2.** Let $g(X, Y)$ be a continuous function on $\mathbb{R}^d \times \mathbb{R}^d$ which is periodic in $Y \in \mathbb{T}^d$, and denote $\bar{g}(X) = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^d} g(X, Y) dY$ its average value over $\mathbb{T}^d$. For any function $f(X)$ in the Schwarz space $\mathcal{S}(\mathbb{R}^d)$, we have

\[(4.5) \quad \int g(X, X/\gamma) f(X) dX = \int \bar{g}(X) f(X) dX + O(\gamma^N),\]

for any $N$.

The formal derivation of the effective equations satisfied by $(\zeta_0, \psi_0)$ is to write (4.1)(4.2) in the sense of distributions, using test functions $f$ that depend only on the large scale variable $X$, averaging over the variables $Y$, and neglecting all the terms that are understood to be of lower order (a rigorous justification of this process will be the object of the next section). Denote the mean value over the $Y$ variables by $(\bar{\zeta}_a, \bar{\psi}_a) = (\frac{1}{|\Gamma|} \int_{\Gamma} \zeta_a(X, Y) dY, \frac{1}{|\Gamma|} \int_{\Gamma} \psi_a(X, Y) dY)$. Then

\[(4.6) \quad \partial_t \bar{\zeta}_a = \partial_t \zeta_0 + \partial_Y \zeta_1 + \sqrt{\mu} \partial_t \zeta_1,\]

and similarly

\[(4.7) \quad \partial_t \bar{\psi}_a = \partial_t \psi_0 + \sqrt{\mu} \partial_t \psi_1 + \mu \partial_t \psi_1.\]

We assume that $\bar{\zeta}_1 = 0$ and $\bar{\psi}_1 = 0$, an assumption that will be shown to be consistent with equations (4.11) and (4.12) derived below. We obtain therefore $\bar{\zeta}_a \simeq \zeta_0$ and $\bar{\psi}_a \simeq \psi_0$ at lowest order. For equation (4.1), using that the $Y$-derivative of a periodic function of $Y$ has mean value zero, we find that

\[(4.8) \quad \partial_t \zeta_0 = -h_0 \Delta \psi_0 - \nabla \zeta_0 \cdot \nabla \psi_0.\]

From equation (4.2), we find

\[(4.9) \quad \partial_t \psi_0 + (\zeta_0 + \sqrt{\mu} \zeta_1) + \frac{1}{2} |\nabla \psi_0|^2 = 0.\]

The lowest order approximation to the system (4.8)(4.9) takes the form of the classical shallow water system (with $V_0 = \nabla \psi_0$ and $h_0 = 1 + \zeta_0$), namely

\[(4.10) \quad \begin{cases} \partial_t \zeta_0 = -h_0 \nabla \cdot V_0 - \nabla \zeta_0 \cdot V_0 \\ \partial_t V_0 + \nabla \zeta_0 + V_0 \cdot \nabla V_0 = 0 \end{cases}.\]

Returning to (4.1)(4.2) and using the equations (4.10) satisfied by $(\zeta_0, \psi_0)$, we obtain at the next order of approximation the equation

\[(4.11) \quad \partial_t \zeta_1 + V_0 \cdot \nabla Y \zeta_1 = |D_Y| \tanh(h_0 |D_Y|) \psi_1 + V_0 \cdot \nabla Y \text{sech}(h_0 |D_Y|) b.\]

If $\bar{\zeta}_1 = 0$ at time $\tau = 0$, it remains so for all times. For the evolution equation for $\psi_1$, we find

\[(4.12) \quad \partial_t \psi_1 + V_0 \cdot \nabla Y \psi_1 + \zeta_1 = 0.\]

Again, if $\bar{\psi}_1 = 0$ at time $\tau = 0$, it remains so for all times.

The result is that (4.10) is the shallow water system (1.9) for $(\zeta_0, V_0)$, with $V_0 = \nabla \psi_0$, and the dispersive corrections are given by (4.11)(4.12). This derivation, and a rigorous justification of it, are the principal subject of this paper.
4.2. Regularity of the approximate solution. The approximate solution is constructed from the solution of a system of simpler model equations (4.10) and (4.11) where the first is a version of the classical shallow water equations. The second is the system for linear water waves in the rapid variables \((Y, \tau)\), with a forcing term due to the presence of bottom variations, whose coefficients depend upon \((\zeta_0(t, X), \psi_0(t, X))\), for which the slow variables are considered as being fixed.

**Theorem 4.3.** For \(r > d/2 + 1\), given initial data \((\zeta_0(\cdot, 0), V_0(\cdot, 0))\) in \(H^r(\mathbb{R}^d) \times H^r(\mathbb{R}^d)^d\) such that (3.4) is satisfied. Then there exists \(T > 0\) and a smooth solution \((\zeta_0, V_0)\) in \(C([-T, T]; H^r(\mathbb{R}^d) \times H^r(\mathbb{R}^d)^d)\) to (4.10) with this initial data.

**Proof.** The shallow water system can be written as a symmetric hyperbolic system for the vector function \((\zeta_0, V_0) = \nabla \psi_0\). For Sobolev index \(r > d/2 + 1\), these equations are locally well posed in time for \((\zeta_0(\cdot, 0), V_0(\cdot, 0)) \in H^r \times H^r\) satisfying the condition (3.4) (see for example [16]).

The components of the corrector \((\zeta_1, \psi_1) = (\zeta_1(\tau, Y; t, X), \psi_1(\tau, Y; t, X))\) are multiple scale functions, satisfying a system of the form

\[
(\partial_{\tau}
\begin{pmatrix}
\zeta_1 \\
\psi_1
\end{pmatrix} + V_0(t, X) \cdot \nabla_Y 
\begin{pmatrix}
\zeta_1 \\
\psi_1
\end{pmatrix}
+ \nabla \psi_0(t, X) \cdot \nabla_Y \begin{pmatrix}
0 \\
1
\end{pmatrix} - |D_Y| \tanh(h_0(t, X)) |D_Y|) 
\begin{pmatrix}
\zeta_1 \\
\psi_1
\end{pmatrix}
= 
\begin{pmatrix}
f \\
g
\end{pmatrix},
\]

for which the large scale variables \((t, X)\) enter as parameters. In the case of equations (4.11)(4.12) the inhomogeneous forcing functions are given by

\[
f(Y; t, X) = V_0(t, X) \cdot \nabla_Y \text{sech}(h_0(t, X)) b(Y), \quad g = 0,
\]

(in particular, it is autonomous, namely independent of \(\tau\), and its zero Fourier mode \(\tilde{f}\) vanishes). Initial data for this system is given in the form \((\zeta_1(0, \cdot; t, X), \psi_1(0, \cdot; t, X))\) in \(H^r(\mathbb{T}^d) \times H^{r+1/2}(\mathbb{T}^d)\) with zero mean on \(\mathbb{T}^d\). The dependence of these solutions on the variables \((t, X)\) will be quantified in a paragraph below.

For the sake of clarity, we omit the dependence on the variables \((t, X)\) in the statement below, since they only act as parameters in (4.13). It is also convenient to introduce the energy or order \(r\) \((r \in \mathbb{R})\) defined for all couple of function \((u, v)\) on \(\mathbb{T}^d\) with zero mean by

\[
\|\langle u, v \rangle\|^2_{E(r)} = \sum_{k \neq 0} (1 + k^2)^r (|\hat{u}_k|^2 + |k| \tanh(h_0(t, X)|k|)) |\hat{v}_k|^2,
\]

where \(\hat{u}_k\) and \(\hat{v}_k\) stand for the Fourier components of \(u\) and \(v\).

**Theorem 4.4.** Let \(r \in \mathbb{R}\). For all \((f, g) \in C(\mathbb{R} : H^r \times H^{r+1/2}(\mathbb{T}^d))\) with zero mean and all \((\zeta_1(0, \cdot), \psi_1(0, \cdot)) \in H^r(\mathbb{T}^d) \times H^{r+1/2}(\mathbb{T}^d)\) with zero mean, there exists a unique solution \((\zeta_1, \psi_1)\) of (4.13) in \(C(\mathbb{R} : H^r(\mathbb{T}^d) \times H^{r+1/2}(\mathbb{T}^d))\) with initial values given by \((\zeta_1(0, \cdot), \psi_1(0, \cdot))\). Moreover, this solution has zero mean and one has

\[
\forall \tau, \quad \|\langle \zeta_1(\tau), \psi_1(\tau) \rangle\|^2_{E(r)} \leq \|\langle \zeta_1(0), \psi_1(0) \rangle\|^2_{E(r)} + \tau \sup_{0 \leq \rho \leq \tau} \|\langle f(\rho), g(\rho) \rangle\|^2_{E(r)}.
\]

This theorem implies that \((\zeta_1, \psi_1)\) is bounded in \(H^r \times H^{r+1/2}\) over any time interval \(\tau \in [-T_1, T_1]\). However, this bound may grow as \(T_1 \to \infty\) due to the possible presence of secular terms. Furthermore, when considering the dependence of this solution on the parameters \((t, X)\), secular growth of the quantities \(\partial_X(\zeta_1, \psi_1), \partial_t(\zeta_1, \psi_1)\) is quite possible, and would affect the validity of the solution decomposition (1.7)(1.8) over long time intervals \(\tau \in [-T/\gamma, T/\gamma]\). In Theorem 4.5, we show that such effects do not occur, at least in the absence of Bragg resonances, and for initial data \((\zeta_1(0, \cdot), \psi_1(0, \cdot))\) chosen to be stationary in the local environment defined by \((\zeta_0, \psi_0)\).
Proof. For the sake of simplicity, we take $g = 0$ in the proof below; the adaptation to the general case is straightforward. Considered independently of the large scale variables $(t, X)$, the system of equations (4.13) over $Y \in \mathbb{T}^d$ has constant coefficients, and the solution operator can be conveniently expressed in Fourier transform. The evolution of the individual Fourier modes is described by the system

\begin{equation}
\partial_\tau \left( \begin{array}{c} \hat{\zeta}_{1k} \\ \hat{\psi}_{1k} \\ \hat{\zeta}_{11k} \\ \hat{\psi}_{11k} \end{array} \right) + \left( \begin{array}{ccc} i k \cdot V_0 & 0 & 0 \\ 0 & i k \cdot V_0 \\ 0 & 0 \\ -\omega_k^2 & 0 \\ I & 0 \\ 0 & -\omega_k^2 \end{array} \right) \left( \begin{array}{c} \hat{\zeta}_{1k} \\ \hat{\psi}_{1k} \\ \hat{\zeta}_{11k} \\ \hat{\psi}_{11k} \end{array} \right) = \left( \begin{array}{c} f_k \\ \hat{f}_k \\ 0 \\ 0 \end{array} \right),
\end{equation}

where the local velocity is $V_0(t, X)$, and the frequency is given by $\omega_k = (|k| \tanh(h_0(t, X)|k|))^{1/2}$, both of which depend parametrically upon the long scale spatial variable $(t, X)$.

Defining new coordinates $u_k := \omega_k^{-1/2} \zeta_{1k}$ and $v_k := \omega_k^{1/2} \psi_{1k}$, the propagator for (4.13)(4.16) is given by

\[
\exp \left[ \tau \left( \begin{array}{cc} -i k \cdot V_0 & 0 \\ 0 & -i k \cdot V_0 \end{array} \right) + \tau \left( \begin{array}{cc} 0 & \omega_k \\ -\omega_k & 0 \end{array} \right) \right] = e^{-i k \cdot V_0 \tau} \left( \begin{array}{cc} \cos(\omega_k \tau) & \sin(\omega_k \tau) \\ -\sin(\omega_k \tau) & \cos(\omega_k \tau) \end{array} \right). 
\]

Using complex notation for this system, define

\[
Z_k := u_k + i v_k, \quad W_k := u_k - i v_k,
\]

with which we express the general solution to (4.16);

\begin{equation}
Z_k(\tau) = e^{-i \tau \omega_k V_0} Z_k(0) + \int_0^\tau e^{-i(\tau - s) \omega_k V_0} \omega_k^{-1/2} f_k(s) \, ds \\
W_k(\tau) = e^{+i \tau \omega_k V_0} W_k(0) + \int_0^\tau e^{+i(\tau - s) \omega_k V_0} \omega_k^{-1/2} f_k(s) \, ds.
\end{equation}

Standard use of the Plancherel identity implies that

\[
\|Z(\tau, \cdot)\|_{H_0^{1/4}}^2 \leq \|Z(0, \cdot)\|_{H_0^{1/4}}^2 + C_0 \tau \|f(\cdot, s)\|_2^2 \int_{[-\tau, \tau]} |f_s\|_{H_0^2}^2 \, ds,
\]

\[
\|W(\tau, \cdot)\|_{H_0^{1/4}}^2 \leq \|W(0, \cdot)\|_{H_0^{1/4}}^2 + C_0 \tau \|f(\cdot, s)\|_2^2 \int_{[-\tau, \tau]} |f_s\|_{H_0^2}^2 \, ds,
\]

where we have used that $\omega_k \sim (k)^{1/2}$. Recovering our original variables

\[
\frac{1}{2} (Z_k + W_k) = u_k = \omega_k^{-1/2} \zeta_{1k}, \quad \frac{1}{2i} (Z_k - W_k) = v_k = \omega_k^{1/2} \psi_{1k},
\]

the result is as stated in Theorem 4.4, with in addition a quantitative estimate on the growth in the fast time variable $\tau$. \qed

4.3. The Bragg resonance condition. Solutions to the linear equation (4.13) exist for all $\tau \in \mathbb{R}$, however $(\zeta_{1}(\cdot, \tau), \psi_{1}(\cdot, \tau))$ may exhibit secular growth in time; more precisely, it may grow linearly with respect to $\tau$. This is a concern for our model system because $\tau = t/\gamma$ is the rapid timescale, therefore over physically relevant time intervals of $O(1)$ in the slow time variable $t$, solutions of (4.13) may grow from $O(1)$ quantities to $O(1/\gamma)$ quantities, thus leaving the range of validity of our assumption regarding the asymptotic scaling regime. This secular growth for Fourier modes $(\zeta_{1k, \psi_{1k}})(\tau)$ is due to the presence of Bragg resonances of the $k^{th}$ Fourier mode of the corrector solution with the periodic variations of the bottom topography defined by $b(Y)$ for which $b_k \neq 0$. Note that these resonances differ from the classical Bragg resonances which are obtained with surface waves and bottoms of comparable wavelength [19]; to our knowledge they had not been exhibited before. Such a resonance occurs at time $t$ and in $X$ if for some $k \neq 0$ such that $b_k \neq 0$,

\begin{equation}
\omega_k(X, t)^2 = (k \cdot V_0(X, t))^2,
\end{equation}

where $V_0 = \nabla \psi_0$, $\omega_k = (|k| \tanh(h_0|k|))^2$.

In absence of such resonances, it is quite easy to check that there is no secular growth of the first corrector: $(\zeta_{1})(\tau, \cdot, t, X), \psi_{1}(\tau, \cdot, t, X)$ remains bounded with respect to $\tau$ in the energy norm (4.15). This easily follows...
from the fact that \((\zeta_1, \psi_1)\) solves (4.13) with a forcing function \(f\) given by (4.14) which is independent of \(\tau\).
The time integral in (4.17), which is at the origin of the secular growth, can then be explicitly computed, and it is obviously bounded in absence of Bragg resonance.

Controlling the error corresponding to our approximation requires however some bound on the parametric derivatives of \(\zeta_1\) and \(\psi_1\) (i.e., their derivatives with respect to \(t\) and \(X\)). These parametric derivatives also solve a problem of the form (4.13), albeit with a different forcing term (\(f, g\)). Theorem 4.4 can therefore be used to give some control on the energy norm of these parametric derivatives; however the forcing term now depends on \(\tau\) and the linear secular growth in \(\tau\) that appears in the estimate of Theorem 4.4 cannot be removed as above.

As previously explained, this secular growth is destructive for our approximation. While it cannot be avoided in general for the parametric derivatives of \((\zeta_1, \psi_1)\), we still have some freedom to eliminate it. Indeed, the choice for the initial condition associated to (4.13) is so far completely arbitrary. It turns out that, in absence of Bragg resonance, there is one choice of initial data that removes the secular growth. This removal is quite spectacular since the corresponding solutions are independent of \(\tau\) (and therefore bounded together with all their parametric derivatives). These constant solutions are found by removing the \(\tau\)-derivative in (4.13)-(4.14) which leads to solving the following problem,

\[
\begin{pmatrix}
V_0 \cdot \nabla Y & -|D_Y| \tanh(h_0|D_Y|) \\
0 & V_0 \cdot \nabla Y
\end{pmatrix}
\begin{pmatrix}
\zeta_1 \\
\psi_1
\end{pmatrix}
= \begin{pmatrix}
0 \\
V_0 \cdot \nabla Y \sech(h_0|D_Y|)b
\end{pmatrix}.
\]

In absence of Bragg resonance, this yields, for all \(k \in \mathbb{Z}\),

\[
\hat{\zeta}_{1,k} = -\frac{(V_0 \cdot k)^2 \sech(h_0|k|)}{-(V_0 \cdot k)^2 + |k| \tanh(h_0|k|)} \hat{b}_k,
\hat{\psi}_{1,k} = -i \frac{(V_0 \cdot k) \sech(h_0|k|)}{-(V_0 \cdot k)^2 + |k| \tanh(h_0|k|)} \hat{b}_k.
\]

A quantitative measure of nonresonance with respect to a sequence \(\{0 < B_k < +\infty : k \in \mathbb{Z}^d\}\) is necessary for the analysis that follows; the \(k\)th Fourier modes \((\hat{\zeta}_{1,k}, \hat{\psi}_{1,k})\) are nonresonant at \((X, t)\) with respect to the homogenized solution \((\zeta_0(\cdot, t), \psi_0(\cdot, t))\) and the bottom topography \(b(Y)\) if \(\hat{b}_k \neq 0\) and one has

\[
|\omega_k(X, t)^2 - (k \cdot V_0(X, t))^2| > \frac{1}{B_k}.
\]

The sequence \(\{B_k\}\) is effectively a bound on the small divisor condition governing Bragg resonances, locally in \((X, t)\). Given a sequence \(\{B_k : k \in \mathbb{Z}^d\}\) such that \(B_k < e^{h|k|/\delta}\), if (4.20) holds for all \(k \neq 0\), a local stationary solution exists, and furthermore the secular growth of local solutions can be controlled locally in \((X, t)\). When (4.20) holds uniformly in \((X, t)\) for all \(\hat{b}_k \neq 0\), it is a nonresonant situation (relative to the small divisor conditions \(\{B_k\}\)) and solutions can be controlled globally.

**Theorem 4.5.** Let \(r \in \mathbb{N}, r' > d/2 + r + 1, T > 0\) and \((\zeta_0, V_0) \in C^r([-T, T]; H^{r'-r}(\mathbb{R}^d)^{1+d})\) be a solution of the shallow water equations (4.10), such that

\[
\exists \alpha_0 > 0, \quad \forall(X, t) \in \mathbb{R}^d \times [-T, T], \quad 1 + \zeta_0(X, t) \geq \alpha_0.
\]

Assume also that the nonresonance condition (4.20) holds with \(B_k < e^{h|k|/\delta}\) (for some \(\delta > 0\) and \(0 < h < \alpha_0\)). Then there exists a unique locally stationary solution of (4.13), which is given by (4.19). In particular, one has, for all \(0 \leq s \leq r' - r\) and all \(s' > 0\),

\[
|\zeta_1|_{C^s([-T, T]; H^s_X \times H^s_Y)} + |\psi_1(\cdot)|_{C^s([-T, T]; H^s_X \times H^s_Y)}
\leq C_{rss'}(|\zeta_0|_{C^s([-T, T]; C^s_X)} + |\psi_0|_{C^s([-T, T]; C^s_X)})(|\zeta_0|_{C^s([-T, T]; H^s_Y)} + |\psi_0|_{C^s([-T, T]; H^s_Y)}))B_L^2.
\]

**Proof.** Let \(F_k := \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}\) defined as

\[
F_k(V, \zeta) = -\frac{(V \cdot k)^2 \sech((1 + \zeta)|k|)}{- (V \cdot k)^2 + |k| \tanh((1 + \zeta)|k|)},
\]
so that $\hat{\zeta}_{a,k} = F(V_0,\zeta_0)\hat{b}_k$. The mapping $F_k$ is smooth, vanishes at the origin, and is rapidly decaying together with all its derivatives as a consequence of the nonresonance assumption (4.20). It follows therefore from Moser’s estimate that

$$|k|^{s'}|\hat{\zeta}_{a,k}|_{C([-T,T];H^s)} \leq C(s,s',|\zeta_0|_{C([-T,T];L^X)},|V_0|_{C([-T,T];L^X)})(|\zeta_0|_{C([-T,T];H^s_X)} + |V_0|_{C([-T,T];H^s_X)})|\hat{b}_k|,$$

so that the bound given in the lemma stems from Plancherel’s inequality in the case $r = 0$. Bounds for $r > 0$ and on $\psi_1$ are obtained in the same way. \[\blacksquare\]

The question as to how often Bragg resonances occur merits a discussion. For $k \neq 0$ fixed, (4.20) is an open condition on the state parameters $(\zeta_0, V_0) \in C^0$. In two dimensions (that is, when $d = 1$), it is related to the local Froude number of the flow, defined by

$$Fr^2(X,t) := \frac{V_0^2(X,t)}{h_0(X,t)};$$

indeed, the nonresonance condition (4.20) can be stated equivalently as

$$Fr^2(X,t) = \frac{\tanh(h_0(X,t)|k|)}{h_0(X,t)|k|}$$

and in particular for supercritical flows $Fr^2(X,t) \geq 1$, Bragg resonances are absent. However, the Froude number is an indication of criticality which is local in $X$, and because $V_0 \in H^s$, solutions can be supercritical only on compact sets. For subcritical flows, and for $(X,t)$ fixed, at most one Fourier mode can be in resonance\(^2\). If $b(Y)$ is a trigonometric polynomial, then there are a finite number of resonances. Any 2-resonances are separated by a region of non-resonance, and for $V_0 \to 0$ as $X \to \pm\infty$ further resonances are avoided. In particular, if $k_{\max}$ denotes the highest nonzero Fourier mode of $b$ and $k_{\min}$ the lowest one, then Bragg resonances are possible only if

$$Fr^2_{\min} \leq Fr^2 \leq Fr^2_{\max}, \quad \text{with} \quad Fr^2_{\min} = \frac{\tanh(h_0(X,t)|k_{\min}|)}{h_0(X,t)|k_{\min}|}, \quad Fr^2_{\max} = \frac{\tanh(h_0(X,t)|k_{\max}|)}{h_0(X,t)|k_{\max}|}.$$

For general $b(Y)$ with infinitely many nonzero Fourier coefficients, any zero of velocity $V_0$ is a point of accumulation of resonances and in particular, small resonant patches will appear because $V_0 \to 0$ as $X \to \pm\infty$. Their asymptotic strength is related to the large $k$-behavior of $|\hat{b}_k|$.

The character of resonance for $d \geq 2$ is different. For $b(Y)$ given by a trigonometric polynomial, resonances are isolated for the same reason as for $d = 1$. In the case of a general $b(Y)$, there is the potential for a dense set of resonances in the state space $(\zeta_0, V_0)$ and not just at $V_0 = 0$. This can be seen through the parametric dependence on $(\zeta_0, V_0)$ of the resonant condition (4.18) in wavenumber space. Given $(\zeta_0, V_0)$, this condition defines a hypersurface $E_k$ in $k \in \mathbb{Z}^d$, which, if it passes through a lattice point $k \in \mathbb{Z}^d$ with $\hat{b}_k \neq 0$, gives rise to a resonance. Even if it does not intersect a lattice point, under arbitrarily small perturbations at $(\zeta_0, V_0)$, it will. Hence the set of resonant states $(\zeta_0, V_0)$ is dense.

Nonetheless, in the measure theoretic sense, Bragg resonances are relatively rare. That is, there is a set of states $(\zeta_0, V_0)$ for which (4.20) is satisfied for all $k \neq 0$, such that its complement has measure less than $C\delta$. Indeed, fix $k \neq 0$. The gradient of the resonance condition with respect to $(\zeta_0, V_0)$ on the curve $E_k$ is non-vanishing, and is of amplitude of order $O(|k|)$. Thus state variables $(\zeta_0, V_0)$ of distance $(B_k|k|)^{-1}$ from $E_k$ will satisfy the nonresonance condition (4.20). The union over $k \neq 0$ of $(B_k|k|)^{-1}$-tubular neighborhoods of the sets $E_k$ consists of the ‘bad’ states, for which there exists at least one near resonance as in (4.20). This union has relative measure bounded above by

$$\sum_{k \neq 0} \frac{1}{|k|B_k} < C\delta.$$

\(^2\)This follows from the fact that $\tanh(x)/x$ is strictly decaying on $\mathbb{R}^+$. 

Therefore the resonant set is dense, but has relatively small measure in the space of states \((\zeta_0, V_0)\). Moreover, we see that the set for which (4.20) is satisfied has the character of a Cantor set.

4.4. **Consistency analysis.** The purpose of this section is to evaluate the error that is made when approximating the solution \((\zeta, \psi)\) of the full water wave problem by the functions (3.1), where the components \((\zeta_0, \psi_0)\) and \((\zeta_1, \psi_1)\) satisfy the effective system of equations (4.9) and (4.11) respectively.

Write the full water wave problem (2.3) as

\[
\begin{align*}
E_1(\zeta, \psi) &= 0, \\
E_2(\zeta, \psi) &= 0.
\end{align*}
\]

where \(E_1\) and \(E_2\) identify with the LHS of equations (2.3). We denote our construction of an approximate solution by \(E_a := (E_1(\zeta_a, \psi_a), E_2(\zeta_a, \psi_a))\), where \((\zeta_a, \psi_a)\) is defined in (1.7)(1.8). For this approximate solution, the error is given by the expression

\[
(4.23) E_1(\zeta_a, \psi_a) = -\sqrt{\mu}(G\psi_a)_{res} - \sqrt{\mu}\partial_t \zeta_1
\]

\[
(4.24) E_2(\zeta_a, \psi_a) = \mu \nabla \psi_0 \cdot \nabla_X \psi_1 + \frac{\mu}{2} |\nabla_Y \psi_1 + \sqrt{\mu} \nabla_X \psi_1|^2 - \mu \partial_t \psi_1
\]

\[
-\mu \left( \frac{1}{\mu} ((G\psi_a)_{eff} + \mu^{3/2}(G\psi_a)_{res}) + (\nabla \zeta_0 + \nabla_Y \zeta_1 + \sqrt{\mu} \nabla_X \zeta_1) \cdot (\nabla \psi_0 + \sqrt{\mu} \nabla_Y \psi_1 + \mu \nabla_X \psi_1) \right)^2.
\]

The statement that the expression \((\zeta_a, \psi_a)\) is a good approximation for the equations (2.3) is made up of a complicated nonlinear expression. It is however a natural norm for this problem since it coincides with the norm of the energy functional associated to the water waves equations.

**Theorem 4.6.** Under the assumptions of Theorem 4.5, the approximate solution \((\zeta_a, \psi_a)\) given by expression (1.7)(1.8) satisfies the following consistency estimates

\[
(4.25) |E_1(\zeta, \psi)|_{L^2} \leq C_a \mu^{3/8},
\]

\[
|E_2(\zeta, \psi)|_{H^{1/2}} \leq C_a \mu^{3/4},
\]

for the error term for the water wave system (2.3). The constant \(C_a\) is of the form

\[
C_a = C_0 \frac{1}{\alpha_0}, |\zeta_0|_{C^4}, |V_0|_{H^4}, |b|_{L^2}.
\]

**Remark 4.7.** The quantities \((\zeta_0, \psi_0, \zeta_1, \psi_1)\) are solutions of the model equations and following Theorems 4.3, 4.4 and 4.5, are bounded along with their derivatives in terms of the initial data. The norm in which the error is measured is relatively weak, the reason being that we are dealing with a problem with fast oscillating functions. It is however a natural norm for this problem since it coincides with the norm of the energy functional associated to the water waves equations.

**Proof.** The first component \(E_1\) satisfies

\[
|E_1(\zeta, \psi)|_{L^2} \leq \sqrt{\mu} |(G\psi)_{res}|_{L^2} \sqrt{\mu} |\partial_t \zeta_1|_{L^2}.
\]

By Proposition 3.10, the norm \(|(G\psi)_{res}|_{L^2}\) is bounded by \(\mu^{-1/8}\). This estimate involves norms of \(\zeta_1, \psi_1\) and their derivatives that can be controlled using Theorem 4.5 in terms of norms of the leading term \(\zeta_0\) and \(\psi_0\). Thus the estimate of the first component of \(E_a\) is shown to be as stated in the theorem.

The second component of the error \(E_2\) is given in (4.24). It is made up of a complicated nonlinear expression. This nonlinear quantity consists of several types of terms, distinguished by whether they depend upon surface variables alone, or whether they depend upon the Dirichlet – Neumann operator and thus on
that each derivation costs a factor $\mu |\nabla|$, which depend upon the quantity $(G\psi)$

\begin{equation}
(4.31)
\end{equation}

on the boundary value problem with periodic oscillatory coefficients. For example,
