Abstract

MDMA or “ecstasy” has been associated with memory deficits during abstinence and intoxication. The human neuropharmacology of MDMA induced memory impairment is unknown. This study investigated the role of 5-HT_{2A} and 5-HT_{1A} receptors in MDMA induced memory impairment. Ketanserin is a 5-HT_{2A} receptor blocker and pindolol a 5-HT_{1A} receptor blocker. It was hypothesized that pretreatment with ketanserin and pindolol would protect against MDMA induced memory impairment.

Subjects (N=17) participated in a double-blind, placebo controlled, within-subject design involving 6 experimental conditions consisting of pretreatment (T1) and treatment (T2). T1 preceded T2 by 30 minutes. T1-T2 combinations were: placebo-placebo, pindolol 20mg-placebo, ketanserin 50mg-placebo, placebo-MDMA 75mg, pindolol 20mg-MDMA 75mg and ketanserin 50mg-MDMA 75 mg. Memory function was assessed at Tmax of MDMA by means of a word learning task, a spatial memory task and a prospective memory task.

MDMA significantly impaired performance in all memory tasks. Pretreatment with a 5-HT_{2A} receptor blocker selectively interacted with subsequent MDMA treatment and prevented MDMA induced impairment in the word learning task, but not in the spatial and prospective memory task. Pretreatment with a 5-HT_{1A} blocker did not affect MDMA induced memory impairment in any of the tasks.

Together, the results demonstrate that MDMA induced impairment of verbal memory as measured in the word learning task is mediated by 5-HT_{2A} receptor stimulation.

Introduction

3,4-Methylenedioxymethamphetamine (MDMA) is the primary psychoactive constituent in the popular party drug Ecstasy. Use of MDMA has consistently been associated with learning and verbal memory deficits in recreational and abstinent users (reviews: Cole and Sumnall, 2003; Morgan, 2000; Parrott, 2001); the prototypical example being a reduction in performance on immediate and delayed word recall tasks. Although the existence of these persistent memory deficits in MDMA users has been well established, their neuropharmacology has been a matter of continuous debate. There is some evidence that these deficits are caused by MDMA induced neurotoxicity as indicated by depleted serotonin (5-HT) levels in MDMA users and by dose response relationships between the extent of exposure to MDMA and the magnitude of memory impairment. Yet, imaging studies demonstrated that memory impairment in ecstasy users was not associated with binding to cortical 5-HT transporters or duration of abstinence, which suggests that memory deficits in MDMA users occur independent of serotonergic neurotoxicity (Reneman, *et al* 2001).

A similar conclusion was drawn by Kuypers and Ramaekers in their 2005 and 2007 papers. They set out to inquire whether memory performance is directly related to 5-HT synaptic availability. They treated 18 recreational MDMA users with single doses of MDMA 75mg in a double blind, placebo controlled study and conducted both a verbal memory test and a spatial memory test during intoxication (i.e. 1-2 hrs post drug) and during withdrawal (i.e. 25-26 hrs post drug). Subjects displayed transient memory impairment during intoxication while they performed at placebo level in the withdrawal phase, when serotonin levels were depleted. These results suggest that memory performance during MDMA intoxication is not directly affected by changes in the availability of 5-HT in the synaptic cleft.

The apparent dissociation between general 5-HT levels and MDMA induced memory impairment raises the question whether MDMA exerts its detrimental effect on memory through other mechanisms than synaptic 5-HT-availability alone. Two interesting possibilities include direct and indirect activation of postsynaptic 5-HT_{2A} and 5-HT_{1A} receptors respectively. It is clear from animal studies that 5-HT_{2A} receptors mediate learning and memory processes (Galizio, *et al* 2009; Kay, *et al* 2010; Trigo, *et al* 2008) although it is not completely obvious whether 5-HT_{2A}

receptor drugs achieve their facilitating and impairing effects through agonism, antagonism or inverse agonism (Meneses, 2002). Still, there appears to be some consensus that a 5-HT_{2A} blockade not only improves learning, but reverses poor memory consolidation conditions associated with, among others, dysfunctional serotonergic neurotransmission (Meneses, 2007a, 2007b) as well. 5-HT_{2A} receptor agonists such as mCPP have been shown to decrease learning and memory in rats (Meneses, 1999). The same mechanism might be responsible for the decrement in learning and delayed recall following MDMA administration, as it has been previously demonstrated that MDMA possesses a moderate affinity for activating the 5-HT_{2A} receptor (Sadzot, *et al* 1989).

A second candidate mechanism by which MDMA could cause its disadvantageous effects on memory is indirect activation of the post-synaptic 5-HT_{1A} receptor. The latter has also been shown to modulate memory performance in animals and humans (Liechti, *et al* 2000; Meneses, 1999; Yasuno, *et al* 2003). PET studies have shown a negative correlation between memory function and 5-HT_{1A} receptor agonists binding in the hippocampus. More specifically, the 5-HT_{1A} agonist tandospirone dose dependently impaired performance in an immediate and delayed word recall task (Yasuno, *et al* 2003). The memory impairing effects of 5-HT_{1A} agonists thus appear identical to those produced by MDMA. It is not known whether MDMA also acts as a direct 5-HT_{1A} receptor agonist. However, it may achieve the same net result by indirectly stimulating postsynaptic 5-HT_{1A} receptors during the short-term increase in availability of synaptic 5-HT for the period of intoxication.

The present study was designed to investigate the role of 5-HT_{2A} and 5-HT_{1A} receptors in MDMA induced memory impairment. Recreational MDMA users performed a number of learning and memory tasks after receiving single doses of MDMA in a placebo-controlled study. In line with previous findings and assumptions, it is hypothesized that (1) an acute dose of MDMA will produce impairments on laboratory measures of learning and memory; (2) MDMA-induced memory impairment will be reversed by pre-treatment with ketanserin, a 5-HT_{2A} receptor antagonist, if impairment is related to direct or indirect stimulation of 5-HT_{2A} receptors; and (3) MDMA- induced memory impairment will be reversed by pre-treatment with pindolol, a 5-HT_{1A} partial agonist, if impairment is related to direct or indirect stimulation of 5-HT_{1A} receptors.

Methods and Materials

Participants

A total of 17 healthy MDMA-users (9 male, 8 female), aged between 19 and 27 (mean (SD) 22.76 (2.75)) participated in the study. They were, with the exception of 2, all mild to moderate users of MDMA who reported to have taken the drug on 1 - 65 separate occasions (mean 10.94) in the previous year. Overall, subjects reported to have taken MDMA 3 to 780 times in their lifetime (mean 72.4 times). When the heavy users were excluded from the analysis, the mean lifetime use of MDMA dropped to 13 times. Subject demographics are presented in table 1.

-- insert table 1 --

Participants were recruited through advertisements in local newspapers and by word of mouth. Subjects were examined by the medical supervisor, who checked vital signs, inclusion criteria (written informed consent, age 18-35 yr, history of MDMA use, free from psychotropic medication; good physical health as assessed by a medical doctor; normal weight as determined by BMI 18-28) and exclusion criteria (addiction according to DSMIV criteria, presence or history of psychiatric or neurological disorder as assessed during a clinical interview; pregnancy; cardiovascular abnormalities; excessive drinking or smoking, i.e. defined as more than 20 standard units of alcohol per week and more than 10 cigarettes per day, hypertension) and took blood samples for standard blood chemistry and haematology.

This study was conducted according to the code of ethics on human experimentation established by the declaration of Helsinki (1964) and amended in Seoul (2008) and approved by the Medical Ethics Committee of the Academic Hospital of Maastricht and Maastricht University. A permit for obtaining, storing and administering MDMA was obtained from the Dutch drug enforcement administration. Subjects were paid for their participation in the study.

Treatments and procedures

Subjects participated in a double-blind, placebo controlled, within-subject design involving 6 experimental conditions consisting of pretreatment (T1) and treatment (T2). T1 preceded T2 by 30 minutes. T1-T2 combinations were: placebo-placebo,

pindolol 20mg-placebo, ketanserin 50mg-placebo, placebo-MDMA 75mg, pindolol 20mg-MDMA 75mg and ketanserin 50mg-MDMA 75 mg. Conditions were separated by minimum wash-out period of 7 days to avoid cross-condition contamination. The 75mg dose of MDMA was selected because it falls within the normal range of recreational use (Gouzoulis-Mayfrank and Daumann, 2009) and has been consistently shown to impair memory performance and produce robust subjective mood changes in a number of previous studies from our lab (Kuypers and Ramaekers, 2005, 2006, 2007; Ramaekers, *et al* 2009). Doses of pindolol 20mg and ketanserin 50 mg represent regular therapeutic doses that block approximately 40% of 5HT_{1A} receptors and 91% of 5HT₂ receptors respectively (Brogden and Sorkin, 1990; Rabiner, *et al* 2000; Sharpley *et al.*,1994)

Order of conditions was balanced over subjects and sessions. All subjects received a training session before onset of the experimental sessions in order to familiarize them with the tests and procedures. Treatments at T1 and T2 were administered using a double dummy technique to synchronize time of maximal drug concentrations (T_{max}). Memory function was assessed by means of a number of memory tasks between 1.5-2 hrs after T2 (at T_{max}), during which time subjects were allowed to watch TV or read a book. In addition, blood pressure and body temperature were assessed as safety measures. A summary of the test day is given in Table 2.

– insert table 2 -

Subjects were asked to refrain from drugs at least a week before the start of the experiment and during the study. Subjects were not allowed to use alcohol on the day prior to an experimental session and were requested to arrive at experimental sessions well rested. Drug and alcohol screens were performed prior to experimental sessions upon arrival of the subject. Drug screens assessed for the presence of benzodiazepines, opiates, cocaine, marijuana, MDMA and (meth)amphetamine. Women were given a pregnancy test. Study treatments were only administered if subjects tested negative for drugs and pregnancy.

Memory tests

Three tests with demonstrated sensitivity (Kuypers and Ramaekers, 2005; Ramaekers, *et al* 2009) to the impairing effects of MDMA on memory were included in the memory task battery.

Word learning task

The Word Learning Task (WLT) is the Dutch language version of the standardized, clinically validated test for verbal memory (Rey, 1958). The test begins with the sequential presentation of 30 monosyllabic common nouns. Each word is shown on the computer display for 2 seconds and the subject has to read them out loud. When the series ends, the subject is required to recall as many words as possible. The number correct is scored as the 1st trial score. Thereupon the same list is presented in the same manner on 2 successive occasions. Numbers correct are scored as before. The main parameter is the sum score of correctly recalled words over 3 trials. After a 30 minute delay, the subject is shown a series of 30 words on the computer display, comprising of 15 words of the original set and 15 new words in random order. He/she was asked to respond as fast as possible to indicate whether the given word was one of the original set. The number of correct recognitions and the average speed (ms) of correct recognitions are recorded as the main dependent parameters (Deelman, *et al* 1980; Schmitt *et al.*, 2001).

Spatial Memory Task

The spatial memory task is based on the spatial localisation task (Vermeeren, *et al* 1995). It assesses short-term memory for non-verbal information. The subject is briefly shown a fixation point in the center of the computer display. Shortly thereafter, a target appears at a random location for 500ms. The subject has to memorize the position of the target and, using a computer mouse, relocate the cursor as accurately as possible over that position. The cursor appears either immediately upon target offset or after a delay of 2 or 4 sec. The subject depresses a button to indicate that the cursor is at the recalled position of the target. The test consists of 75 trials, divided equally among 3 response delays. The sequence of delays is random. Mean localisation error (mm) and average reaction time (ms) are the main parameters.

Prospective memory task

The prospective memory task is a new paradigm (Ramaekers, *et al* 2009) that was developed to examine prospective memory performance in an event based memory task. The foreground task consists of 100 successive presentations of a letter (A or B) in the center of a computer screen. Subjects are required to respond to each letter as quickly as possible by pressing one of two response buttons. One button is pressed to indicate that the letter “A” appeared and the other to indicate the letter “B”. Both letters are presented equally often. Subjects are informed about the trial number by means of a trial counter that is always present in the left top corner of the screen. In addition, subjects are presented at irregular times with a future trial number in the right top corner of the display. Subjects are instructed to remember this future trial number and withhold from responding to the foreground task during the actual occurrence of the future trial. The memory set of trial numbers is dynamic and contains up to 3 future trial numbers. A trial number in the memory set is replaced by a novel future trial number whenever the actual trial number matches a future trial number in the set. Trials during which subjects are expected to respond are classified as Go trials. Trials during which subjects are instructed to withhold a response are classified as No Go trials (prospective memory trials). Time between presentation of a future trial number and the actual occurrence of the trial (i.e. memory delay) varies between 1, 2 and 3 minutes, equally divided over all No go trials. In total, the prospective memory task consists of 68 Go trials and 24 No go trials. Number of correct prospective memory recalls (i.e. number of correct response inhibitions) in No go trials is the primary dependent performance parameter.

Pharmacokinetics

Blood samples were collected before the start of the memory tasks at 1.5 hrs post T2. Blood samples were centrifuged immediately and the serum was subsequently frozen at -20°C until analyses for pharmacokinetic assessments. MDMA, pindolol and ketanserin concentrations were determined using solid phase extraction and gas chromatography with mass spectrometric detection.

Statistics

The hypotheses that pretreatment with ketanserin or pindolol would interact with MDMA induced memory impairment was tested in 2 separate General Linear Model (GLM) analyses. Memory effects of MDMA, Ketanserin and MDMA x Ketanserin were analyzed by means of a GLM repeated measures ANOVA with MDMA (2 levels, i.e. present-absent) and Ketanserin (2 levels; present-absent) as the main factors (GLM 1 see Table 2). Memory effects of MDMA, Pindolol and MDMA x Pindolol were analyzed by means of a GLM repeated measures ANOVA with MDMA (2 levels, i.e. present-absent) and Pindolol (2 levels: present-absent) as the main factors (GLM 2, see Table 2). In case of a significant interaction between MDMA and Ketanserin or MDMA and Pindolol, additional drug-placebo contrasts were conducted in order to further elucidate the nature of the interaction. The alpha criterion significance level was set at $p = 0.05$. Safety measures were analyzed in the same manner as measures of memory performance. All statistical tests were conducted with SPSS version 15.0.

Results

Seventeen complete data sets entered statistical analysis. Statistical analysis of memory data is described in detail below. A summary of main effects on measures of memory performance is given in Table 3.

Word learning task

MDMA significantly decreased immediate recall in both the ketanserin and pindolol comparisons ($F_{1,16} = 12.1$; $p < .003$ and $F_{1,16} = 69.1$; $p < .001$ respectively). Ketanserin did not affect memory but significantly interacted with MDMA to prevent impairment of immediate recall ($F_{1,16} = 11.7$; $p = .004$). Pindolol neither affected immediate recall nor interacted with the effect of MDMA on memory. Separate drug-placebo contrasts supported ANOVA and revealed memory impairment only after treatment with MDMA ($p = .001$) and the combination of pindolol with MDMA ($p = .024$). Mean (SE) immediate recall scores in each treatment condition are given in Figure 1. Recognition scores were not affected by MDMA, nor by pindolol or ketanserin.

Prospective Memory Task

MDMA significantly increased the number of prospective memory failures in the NoGo trials in one of the GLM comparisons ($F_{1,16} = 7.8$; $p=.013$) and showed a trend in the other ($F_{1,16} = 4$; $p=.06$). The factors Ketanserin and Pindolol or their interaction with MDMA did not affect prospective memory. Mean (se) prospective memory failures as a percentage of the total prospective memory trials in each treatment condition are given in Figure 1.

-----Insert Figure 1-----

Spatial Memory Task

MDMA significantly increased localisation error in both GLM comparisons ($F_{1,16} = 19.26$; $p<.001$ and $F_{1,16} = 10.4$; $p=.005$). The factor ketanserin also significantly increased localisation error ($F_{1,16} = 10.5$; $p=.005$). MDMA did not interact with any of the pretreatments. In addition, MDMA significantly decreased reaction time in both GLM comparisons ($F_{1,16} = 7.48$; $p=.015$ and $F_{1,16} = 32.42$; $p<.001$). The factors pindolol, ketanserin or their interaction with MDMA did not affect reaction time. Mean localisation error and reaction time in all treatment conditions are shown in Figure 2.

---- Insert Fig 2 and Table 3-----

Safety data

Safety data revealed a significant main effect of MDMA ($F_{1,16} = 24.5$; $p<.001$), pindolol ($F_{1,16} = 26.7$; $p<.001$) and ketanserin ($F_{1,16} = 4.48$; $p<.05$) on blood pressure. Overall, mean blood pressure ranged from 73,6 to 87,3 mmHg over all treatments. MDMA increased mean blood pressure by 7 mmHg relative to placebo, whereas ketanserin and pindolol mildly reduced mean blood pressure relative to placebo. However, ketanserin and pindolol did not interact with the effect of MDMA on blood pressure. Mean body temperature ranged from 36,2 – 36,8 °C over all treatment conditions. Overall, MDMA increased body temperature ($F_{1,16} = 4.4$; $p<.05$). Relative to placebo, body temperature increased by 0.2 °C after MDMA alone. Pretreatments did not affect body temperature or the effect of MDMA on body temperature.

Pharmacokinetics

Mean drug concentrations in all treatment conditions are shown in Table 4.

--- Insert Table 4----

Discussion

The goal of the present study was to investigate the role of 5-HT_{2A} and 5-HT_{1A} receptors in MDMA induced memory impairment. Subjects were given single doses of MDMA combined with placebo, ketanserin or pindolol, after which several learning and memory tasks were performed.

Single doses of MDMA produced memory impairments in all memory tasks. GLM analyses revealed that overall, MDMA decreased immediate recall in the WLT, increased the number of prospective memory failures in the Prospective Memory Task and increased localisation error in the Spatial Memory Task. These results are fully in line with previous studies that have reported identical memory impairments during intoxication with MDMA (Kuypers and Ramaekers, 2005, 2007; Ramaekers, *et al* 2009) as assessed in identical memory paradigms. These results basically indicate that the current memory paradigms were sensitive to the impairing effects of MDMA and should serve as reliable models to assess changes in MDMA induced memory impairments after pretreatments with 5-HT_{1A} and 5-HT_{2A} receptor blockers, the main goal of the present study.

The hypotheses that pretreatment with ketanserin or pindolol would interact with MDMA induced memory impairment was tested in 2 separate GLM analyses that assessed main effects of MDMA, Ketanserin and MDMA x Ketanserin and main effects of MDMA, Pindolol and MDMA x Pindolol respectively. The GLM models were chosen because they offer a robust and direct assessment of the interaction between pretreatments and MDMA in only 2 major analyses. This procedure was much preferred over the alternative approach of multiple comparisons between drug-drug and drug-placebo that can only provide indirect evidence of pretreatment-treatment interactions. Consequently, the present study only conducted drug-placebo contrasts as supportive, secondary tests following a significant interaction between pretreatment and MDMA as evinced by GLM ANOVA.

GLM analyses revealed only one significant interaction between pretreatment-treatment in the 3 memory tasks. In the WLT, pretreatment with ketanserin prevented impairment of word learning during treatment with MDMA. Separate drug-placebo contrasts also provided indirect and supportive evidence of the interaction between ketanserin and MDMA. T1-T2 combinations of placebo-MDMA and pindolol-MDMA both produced significant reductions in immediate recall. Drug-placebo contrasts also showed that performance in the word learning task after combination of ketanserin and MDMA did not differ from that during the placebo-placebo combination. Together these data strongly suggest that MDMA-induced impairments on verbal memory are in large part caused by direct or indirect stimulation of the 5-HT_{2A} receptor. The present finding appears in line with a previous report on 5-HT_{2A} receptors densities in recent MDMA and ex-MDMA users (Reneman, *et al* 2002). That study showed that 5-HT_{2A} receptor densities were significantly lower in recent MDMA users and significantly higher in ex-MDMA users. The authors speculated that the latter was evidence of compensatory upregulation of post-synaptic 5-HT_{2A} receptors due to low synaptic 5-HT levels. The present study suggests that down regulation of 5-HT_{2A} receptors in recent MDMA users may result from high synaptic levels of 5-HT and 5-HT_{2A} receptor stimulation during MDMA intoxication. Studies showing involvement of 5-HT₂ receptors in acute MDMA intoxication as well as in persistent memory impairments in chronic MDMA users indicate that these phenomena may share related underlying mechanisms. Any definitive conclusion in that direction however remains premature since we do not know at present whether acute and chronic memory effects of MDMA are truly interconnected.

Pretreatment with pindolol did not affect memory impairments in any of the memory tasks after treatment with MDMA. The interaction between pindolol and MDMA never reached statistical significance in any of the GLM analyses. These data suggest that 5-HT_{1A} receptors do not play a crucial role in the neuropharmacology of MDMA induced memory impairment. These finding confirm recent results from a study assessing the role of 5-HT_{1A} receptors on MDMA effects on visual-spatial working memory as measured with a CANTAB test battery (Hasler, *et al* 2009) in a placebo-controlled study. A single dose of MDMA significant impaired visual-spatial memory as compared to placebo. However, pretreatment with pindolol did not significantly alter MDMA induced impairment of memory. It should be noted however that Pindolol is not a very selective drug. It is basically a beta-blocker that

also blocks approximately 40% of 5HT_{1A} receptors in the brain (Rabiner, *et al* 2000). Unfortunately, 5HT_{1A} ligands that selectively and fully block 5HT_{1A} receptors are presently not available. Nevertheless, recent molecular imaging studies also suggested that 5-HT_{1A} receptors may not be involved in human cognition at all (Borg, 2008; Borg, *et al* 2006). These studies failed to find any correlation between regional [11C]WAY 100635 binding to 5-HT_{1A} receptors and cognitive performance in humans as measured with standard neuropsychological tests batteries (Borg, 2008; Borg, *et al* 2006). Together, these results question the role of 5-HT_{1A} receptors in human memory, as it cannot explain the general memory deficit in MDMA users.

The present study did not provide clues to neuropharmacological mechanisms of MDMA induced impairments in every memory domain. The preventive effect of ketanserin on MDMA induced memory impairment was selective for verbal memory performance in the Word Learning Task. Ketanserin did not affect spatial memory and prospective memory impairments following MDMA. The selectivity of the interaction between ketanserin and MDMA on verbal memory was also supported by the lack of any interactions between pretreatment and MDMA on safety measures such as blood pressure and body temperature. The latter finding is in line with a previous study that demonstrated that co-administration of ketanserin did not alter MDMA effects on physiological measures (i.e. blood pressure, heart rate and body temperature) and subjective measures (e.g. well being and positive mood) (Herin, *et al* 2005; Liechti, *et al* 2000).

The selective interaction between ketanserin and MDMA effects on verbal memory may indicate differences in neural memory networks and differences in distributions of 5-HT_{1A} and 5-HT_{2A} receptors within these networks. It is clear from the functional neuroimaging literature that frontal, parietal and occipitotemporal cortex are generally involved in a large variety of memory tasks, but that the pattern of brain recruitments within these networks may differ as a function of memory task or memory process (Linden, 2007). Autoradiographic mapping of 5-HT₁ and 5-HT₂ receptors in rhesus monkeys demonstrated complementary patterns of distribution of 5-HT₁ and 5-HT₂ receptors in cortical areas of frontal, parietal and occipital lobes. 5-HT₁ receptors were concentrated in layers I-III, whereas 5-HT₂ receptors were primarily concentrated in throughout layers III and IV (Lidow, *et al* 1989). Involvement of 5-HT_{2A} receptors in MDMA induced memory impairment thus may depend on task related network activations that occur within these layers.

Recent studies have also shown that a functional genetic polymorphism of the 5-HT_{2A} receptor (His452Tyr) has been associated with variations in memory performance, more specifically in hippocampus-dependent memory tasks (Schott, *et al* 2011; Sigmund, *et al* 2008). Future studies may focus on whether genetic variation of the 5-HT_{2A} receptors affects the magnitude of MDMA induced verbal memory impairment or determines the sensitivity of MDMA users for MDMA induced impairment of verbal memory.

In sum, the present study demonstrated that single doses of MDMA impaired memory in a range of tasks, and that pretreatment with ketanserin offered selective protection against MDMA induced verbal memory impairment. This demonstrates that MDMA induced verbal memory impairment is mediated by 5-HT_{2A} receptor stimulation.

Table/Figure legends

Table 1_ Subject demographics – drug history (lifetime use in number of times used).

	Mean	SD	Min	Max
Age (years)	22,76	2,75	18,6	27,2
Height (cm)	179,6	12,3	160,0	200,0
Weight (kg)	72,9	14,7	56,0	110,0
Alcohol	1168,5	794,1	260,0	2600,0
Cannabis	554,4	1104,8	0,0	3650,0
Ecstasy	72,4	194,7	3,0	780,0
Amphetamines	4,1	12,3	0,0	49,0
Cocaine	4,7	7,3	0,0	25,0
LSD	4,4	12,0	0,0	50,0
Mushrooms	0,2	0,5	0,0	2,0
Other	0,5	1,7	0,0	7,0

Table 2. Schematic representation of a testing day in 6 treatment conditions. During pre-treatment (T1) subjects received either placebo, ketanserin 50mg or pindolol 20mg. Treatment (T2) consisted of either MDMA 75mg or placebo.

9:00	9:30 T1	10:00 T2	11:30	11:30-13:00

Table 3 Summary of main effects and interactions following 2 major GLM analyses for all dependent variables in the Word Learning Task (WLT), the Prospective Memory Task (PMT) and the Spatial Memory Task (SMT). Significance ($p < .05$) and non-significance (-) of main effects is shown.

GLM 1: Factors MDMA (present – absent) and Ketanserin (present – absent) Treatments included PLA-PLA, PLA-MDMA, KET-PLA and KET-MDMA				
	WLT Immediate recall	PMT Prospective recall	SMT Localisation error	SMT Reaction time
Main effects				
MDMA	.003	.013	.001	.015
Ketanserin	-	-	.005	-
MDMA x Ketanserin	.004	-	-	-
GLM 2: Factors MDMA (present – absent) and Pindolol (present – absent) Treatments included PLA-PLA, PLA-MDMA, PIN-PLA and PIN-MDMA				
	WLT Immediate recall	PMT Prospective recall	SMT Localisation error	SMT Reaction time
Main effects				
MDMA	.001	-	.005	.001
Pindolol	-	-	-	-
MDMA x Pindolol	-	-	-	-

Table 4. Dose and mean (SD) drug concentrations in each of the 6 treatment conditions. During pre-treatment subjects received either placebo, ketanserin 50mg or pindolol 20mg. Treatment consisted of either MDMA 75mg or placebo. Each treatment condition consisted of a pre-treatment (T1) and a treatment (T2). (PLA=placebo, PIN=pindolol, KET=ketanserin, MDMA=3,4-methylenedioxymethamphetamine).

T1	PLA	PIN	KET	PLA	PIN	KET
T2	PLA	PLA	PLA	MDMA	MDMA	MDMA
Dose (mg)	-	20	50	-	20	50
	-	-	-	75	75	75
Cmean (ng/mL)	-	133 (80)	86 (42)	-	130 (53)	104 (41)
	-	-	-	157 (48)	156 (56)	164 (62)

-insert figure 1-

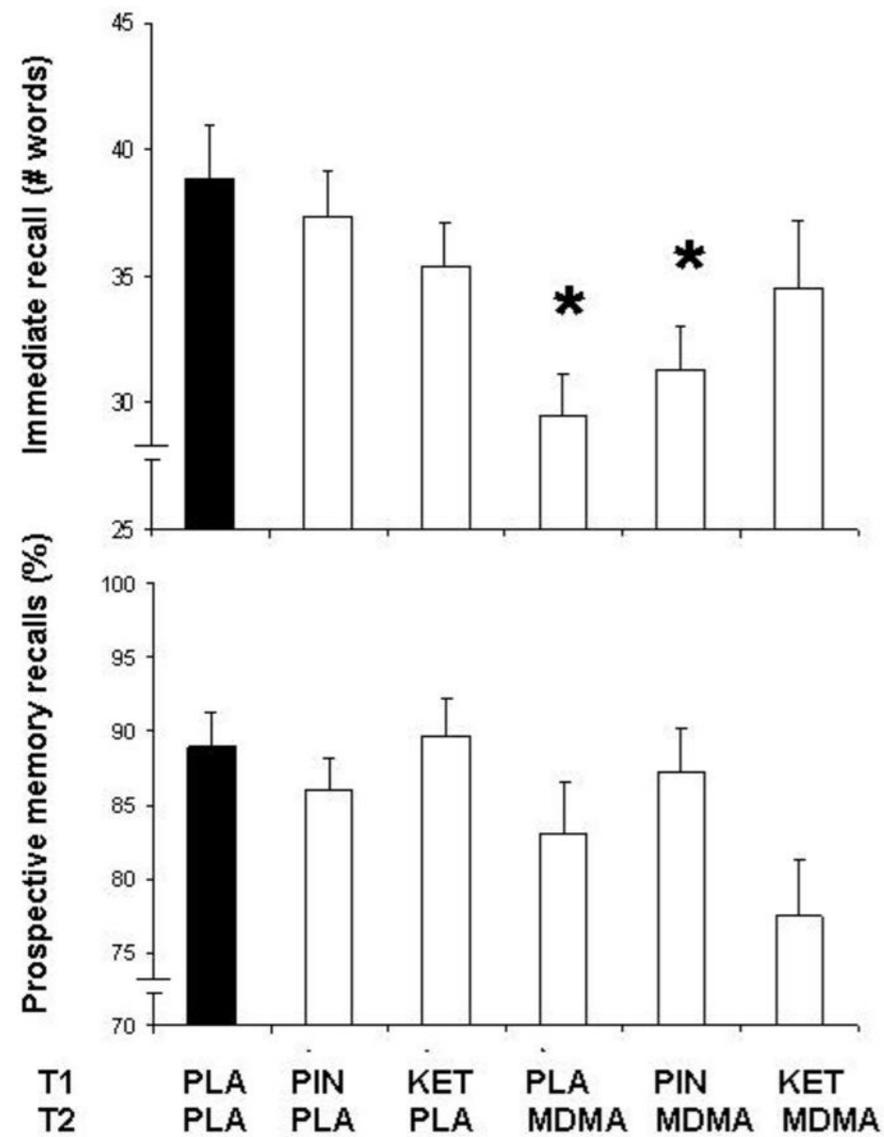

Figure 1.

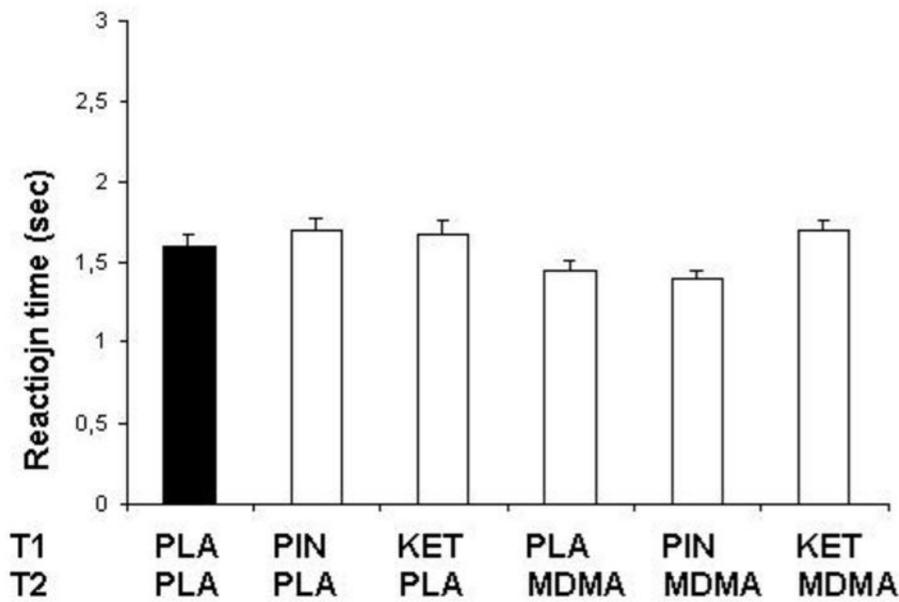

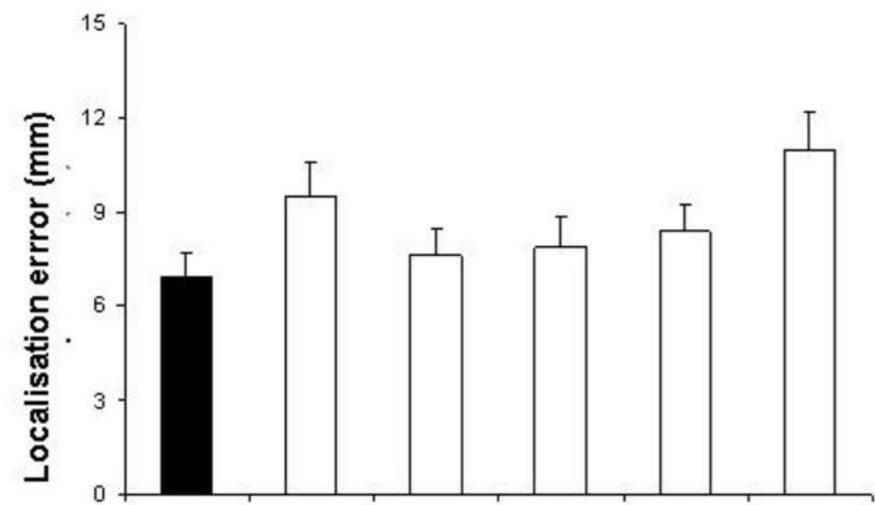

Mean (SE) immediate recall and prospective memory recall in the word learning task and the prospective memory task for every treatment condition. Each treatment condition consisted of a pre-treatment (T1) and a treatment (T2). (PLA=placebo, PIN=pindolol, KET=ketanserin, MDMA=3,4-methylenedioxymethamphetamine, * = $p < .05$ as indicated by drug-placebo contrasts following a significant main interaction effect of MDMA x Ketanserin in the Word Learning Task).

-insert figure 2-

Figure 2.

Mean (SE) localisation error and reaction time in the spatial memory task for every treatment condition. Each treatment condition consisted of a pre-treatment (T1) and a treatment (T2). (PLA=placebo, PIN=pindolol, KET=ketanserin, MDMA=3,4-methylenedioxyamphetamine).
