HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Biomechanical role of collagen cross-links in bone strength: finite element study.

Introduction:

Bone contains exclusively genetic Type I collagen. These collagens are identical sequences of amino acids that form the tropocollagen molecules linked by cross-links found at the end of each tropocollagen molecules. Collagen cross-linking, a major post-translational modification of collagen, plays important roles in the biological and biomechanical features of bone. The aim of this work is to use a 3D nano-scale finite element model of a sub structure in collagen fibril called mineralized collagen microfibril and to investigate the important roles of cross-links in the expression of bone strength and its capacity and ability to absorb energy. Studies in vitro and in vivo have reported that increases in cross-linking are associated with enhancement of some mechanical properties (strength and stiffness) and reductions of others (energy absorption). These experimental data are limited in their ability to define individual biomechanical effects of altered cross-linking. In the present work the study of the effect of cross-links is more realistic that's because the proposed finite element model success to combines the collagen, mineral and cross-links furthermore been able to varying the mechanical and geometry properties of each phase and to visualize their influence on corresponding equivalent properties of the collagen microfibril.

Materials and Methods

A 3D finite element model of collagen microfibril with symmetric and periodic boundary conditions is considered here, with an array of 5 TC cross-linked together, the all is put into a mineral matrix. A parametric study was performed in order to investigate the influence of varying number of cross-links on the mechanical behaviour of the microfibril. This Finite element model was coupled to a UMAT and optimization algorithm to calculate the equivalent proprieties of microfibrils. From a FE point of view, spring elements can be used to model connections between two different regions to couple a force with a relative displacement representing the elasticity of the physical connecting constituents (physical cross links).

Results:

In this study results were obtained under tensile loading with symmetric and periodic boundary conditions. These results show that the number of cross-link has a most influence on the increase in the elastic and failure proprieties. at constant Young's modulus, if the number of cross-link (N) increase the bone material will be more stronger, however when $N > 20$ fracture stress does not depend on the cross-link number and it remains at constant value "plateau value", same observation has been also found by Markus J.Buehler [1] in his molecular multi-scale study. Where it is found that fracture stress depend on the cross-link density" β " only when $\beta < 25$. This plateau can be explained by the fact that whenever the number of cross link increases their stiffness increases up a threshold value hence the behaviour of all collagen-cross-links becomes insensitive to the number (N), this explanation is demonstrated by an analytical calculation.
