ABSTRACT

This paper examines the effect of human capital on the growth of ICT-intensive industries using data from a sample of open economies over the period 1980-1999. Our econometric analysis suggest that value added and employment in ICT-intensive industries grew relatively faster in countries with a higher *ex-ante* human capital stock and in countries with a fast improvement in human capital. Further, in countries with fast human capital accumulation, labour productivity in ICT-intensive industries grew faster. Our results are robust to controls for other determinants of industry growth and country characteristics affecting industry specialisation and to using alternative human capital measures.

Key words: Human capital, ICT industries, Economic growth

JEL classification: E62, F43, O33

INTRODUCTION

This paper examines the relationship between human capital and the growth of Information and Communication Technologies (ICT)-intensive industries using data from a sample of open economies over the period 1980-1999.

The question whether human capital fosters economic growth, in particular the growth of ICT-intensive industries is interesting and relevant for both research and policy. First, notwithstanding a well-established theoretical literature showing positive effects of human capital on economic growth, existing empirical evidence is mixed. Second, ICT are at the core of the knowledge-driven economy and there is growing evidence suggesting that ICT-linked knowledge, innovation and technological changes are strong determinants of growth differentials and the ability of countries to benefit from globalisation. While earlier studies have found little evidence of a link between ICT and growth, more recent studies point to a positive effect of ICT investment on growth (Oliner and Sichel 2000; OECD 2000; Timmer and van Ark 2005; van Ark, O'Mahony and Timmer 2008). The role of ICT-intensive industries on growth is threefold. First, to the extent that ICT industries grow faster than the other industries, their contribution to output growth can be significant (OECD 2000). Second, it has been shown that industries with higher shares of ICT in total capital experienced larger gains in productivity growth (Jorgenson and Stiroh 2000; Inklaar et al. 2008). Third, a growing literature points to positive spillovers generated by ICT use such as learning-by-doing effects, and accompanying organisational change as well as network effects (Katz and Shapiro 1994; Liebowitz and Margolis 1994). To the extent that such spillover effects and externalities exist they can raise overall total factor productivity (TFP). Carlsson (2004) and Hollestein (2004) find evidence

1
2 suggesting that ICT had a positive effect on economic growth via new products and
3
4 services and new organisation methods. Third, our research about the relationship
5
6 between human capital and growth in ICT-intensive industries is relevant for
7
8 education policy.
9

10
11 The theoretical literature¹ indicates several channels through which human
12
13 capital affects economic growth. Nelson and Phelps (1966) show that high levels of
14
15 human capital facilitate the adoption of new technologies. In contrast to this view,
16
17 Lucas (1988) focuses on skill acquisition as an input in an aggregate production
18
19 function. Romer (1990) allows for the possibility that both the stock as well as the
20
21 growth of human capital generate ideas for new designs and goods which in turn
22
23 endogenously drive physical capital investment and growth. Mankiw, Romer and
24
25 Weil (1992) add human capital accumulation to the neoclassical Solow growth model
26
27 and show that this augmented model explains better the cross-country differences in
28
29 income per capita.
30
31
32
33
34

35 Most empirical analyses use educational attainment as a proxy for human
36
37 capital and investigate the relationship between the level of education or education
38
39 improvement and output growth at country level. The estimated output growth models
40
41 are based on a standard Cobb-Douglas aggregate production function in which labour,
42
43 human and physical capital enter as factors of production. The empirical results
44
45 obtained with cross-country growth regressions are mixed. While Romer (1990) and
46
47 Benhabib and Spiegel (1994) found a positive effect of the human capital level on
48
49 output growth, Cohen and Soto (2007) found no significant effect. The same mixed
50
51 evidence has been found in the case of the relationship between improvements in
52
53 human capital and growth. In contrast to a significant positive correlation between
54
55 improvements in human capital and growth found by Temple (1999), Cohen and Soto
56
57 (2007), de la Fuente and Doménech (2006), no effect of human capital improvement
58
59
60

1 on growth is found in other studies (Benhabib and Spiegel 1994; Barro and Sala-i-
2 Martin 1995; Caselli, Esquivel and Lefort 1996). Furthermore, Topel (1999) and
3
4
5
6
7 Krueger and Lindhal (2001) find a positive effect of the human capital level as well as
8
9 human capital improvement on economic growth.

10
11 Cross-country growth regressions have several shortcomings (for example, no
12 controls for unobserved heterogeneity, limited degrees of freedom, among others).
13
14 Analysis at industry level across countries can correct for these limitations by
15
16 exploiting the within country variation between industries. Rajan and Zingales (1998)
17
18 use a cross-country cross-industry analysis to examine whether financial development
19
20 fosters economic growth. They find that industries that are dependent on external
21
22 finance grew faster in countries with more developed financial markets. Using a
23
24 similar analysis at industry level in a large sample of countries, Ciccone and
25
26 Papaioannou (2009) find that schooling-intensive industries grew relatively faster in
27
28 countries that initially had higher levels of human capital and in countries with fast
29
30 human capital improvement. Hirsch and Sulis (2008) provide additional empirical
31
32 evidence on the positive effect of both the initial level of human capital and human
33
34 capital improvement on the growth of value added and labour productivity across
35
36 regions and industries in Italy. In contrast to findings of Ciccone and Papaioannou
37
38 (2009) they find no significant effect of human capital on industry employment
39
40 growth.
41
42
43
44
45
46
47
48

49 Following the seminal paper by Nelson and Phelps (1966), a large empirical
50 literature has focused on the relationship between human capital and new technology
51 adoption. Chun (2003) provide empirical evidence from the US over 1960-1996
52 showing that highly educated workers were more likely to implement new
53 technologies such as information technology (IT). The adoption and use of IT
54 accounted for a large proportion of the increase in the demand for educated workers
55
56
57
58
59
60

1 over the period 1970-1996. Bartel and Sicherman (1999) find a positive correlation
2 between the education premium of workers and technological change at industry
3 level. Caselli and Coleman (2001) find that the educational attainment was an
4 important determinant of the level of investment in computers in a sample of OECD
5 countries over the period 1970-1990. Firm-level evidence suggests that firms using
6 advanced technology employ more skilled workers. Doms et al. (1997) use plant-level
7 data from the US and find a positive correlation between the education of workers and
8 the use of new technology. Furthermore, they find that plants that invested relatively
9 more in computing equipment had a higher increase in the share of non-production
10 workers. Similar evidence supporting the hypothesis that the presence of highly
11 skilled workers fosters innovation and facilitates ICT adoption and use at firm level
12 was found in other studies (Arvanitis 2005; Bresnahan et al. 2002; Fabiani et al. 2005;
13 Falk 2005; Bayo-Moriones and Lera-López 2007).

33 Our analysis builds on and extends the analysis by Ciccone and Papaioannou
34 (2009). In particular, we investigate the effect of human capital on growth of ICT-
35 intensive industries using measures for both the initial *stock* of human capital and the
36 *accumulation* of human capital. We identify an independent effect of human capital
37 on the growth of ICT-intensive industries over and above the effect of human capital
38 on the growth of output and employment of schooling-intensive industries found by
39 Ciccone and Papaioannou (2009). In addition, we extend our analysis to the effect of
40 human capital on productivity growth.

49
50
51 The main finding of this paper is that in open developed countries, human
52 capital is an important factor driving the growth of ICT-intensive industries.
53 Specifically, on average, other things equal, in countries with an *ex-ante* high human
54 capital stock and in countries with a rapid human capital accumulation, value added
55 and employment in ICT-intensive industries grew relatively faster. Further, in
56
57
58
59
60

1 countries with fast human capital accumulation, labour productivity in ICT-intensive
2 industries grew faster. This effect of human capital on growth in ICT-intensive
3
4
5
6
7 appears to be positive and significant over and above the effect of human capital on
8
9 schooling-intensive industries. These results are robust to controls for other factors
10
11 affecting industry growth, country characteristics affecting industry specialisation and
12
13 alternative measures of human capital. In addition, while our results are stronger for a
14
15 a data set of mainly manufacturing industries they hold when we estimate the model
16
17 with a larger set of industries including services.
18
19

20
21 The remainder of this paper is organised as follows. Next Section outlines our
22
23 empirical strategy, model specifications and explains how we account for potential
24
25 econometric issues. Data that we use in our analysis is described next followed by a
26
27 discussion of the results of our empirical analysis. The final Section concludes.
28
29
30
31

32 **EMPIRICAL STRATEGY AND MODEL SPECIFICATION**

33
34 This paper examines the relationship between human capital at country level and
35
36 growth of ICT-intensive industries. To this purpose, we estimate an augmented
37
38 aggregate production function model. Specifically, we focus on within country
39
40 between industry variation building on the methodology used by Rajan and Zingales
41
42 (1998) and Ciccone and Papaioannou (2009). On the basis of the theoretical and
43
44 empirical background discussed above, we test the hypothesis that ICT-intensive
45
46 industries grew faster in countries with an initial high stock of human capital and in
47
48 countries with greater improvement in human capital. We first examine the link
49
50 between human capital and value added growth and then extend the analysis to the
51
52 effects of human capital on productivity and employment growth.
53
54
55
56
57

58
59 To identify the effect of human capital on industry growth we estimate the
60
following benchmark model:

$$\Delta \ln y_{i,k,T} = \lambda_i + \mu_k + \alpha_1 (hc_{i,t_0} * ict_{k,t_0}) + \alpha_2 (\Delta hc_{i,T} * ict_{k,t_0}) + \alpha_3 (hc_{i,t_0} * hc_{k,t_0}) + \alpha_4 (\Delta hc_{i,T} * hc_{k,t_0}) + \alpha_5 (k_{i,t_0} * k_{k,t_0}) + \alpha_6 \ln y_{i,k,t_0} + \varepsilon_{i,k} \quad (1)$$

In the above model, the dependent variable ($\Delta \ln y_{i,k,T}$) is the average annual growth rate of real gross value added (or the average annual growth rate of labour productivity or average annual growth rate of employment) in industry k within country i over the analysed period T. The explanatory variables of interest are the country level initial human capital stock (hc_{i,t_0}) and human capital accumulation ($\Delta hc_{i,T}$) interacted with a measure of industry level ICT intensity (ict_{k,t_0}). Our theoretical prior is that $\alpha_1 > 0$ and $\alpha_2 > 0$.

Further, we control for other determinants of industry growth suggested by the recent relevant theoretical and empirical literature (Rajan and Zingales, 1998; Ciccone and Papaioannou 2009). To this purpose, the following two interactions capture the effect of country level initial human capital stock and human capital accumulation on the growth of human capital intensive industries. hc_{k,t_0} denotes human capital intensity in industry k in the base year. We control for the role of physical capital on growth by adding an interaction between the country level initial capital-output ratio (k_{i,t_0}) and industry level capital intensity (k_{k,t_0}). The initial level of gross value added, $\ln y_{i,k,t_0}$ (or the initial level of employment) account for differences in industry size.

In addition, we control for country-specific (λ_i) and industry-specific (μ_k) growth effects. Country-specific growth effects include unobserved factors affecting economic growth at country level. Industry-specific growth effects include unobserved industry characteristics such as industry-specific technological progress. Thus, our model specification explains the within country between industries variation of growth. We thus isolate the effect that human capital at country level has on growth of ICT-intensive industries relative to country and industry means.

1
2 Detailed definitions of variables and data sources are given in Table A1 in the
3
4 Appendix. We estimate the equation (1) by ordinary least squares (OLS) and
5
6 instrumental variables (IV) to account for the possibility that the accumulation of
7
8 human capital could be endogenous as countries with a high income level or fast
9
10 growing economies are able to allocate a higher proportion of their resources to
11
12 education (Gemmel 1996). In addition, decisions to invest in education might be
13
14 affected by industry growth in human capital intensive industries (Ciccone and
15
16 Papaioannou, 2009). We do not treat the level of human capital in 1980 as
17
18 endogeneous since it is less likely that this was affected by expected growth in human
19
20 capital-intensive industries².
21
22
23
24

25 Further, we carry out a sensitivity analysis to check the robustness of our
26
27 results to additional control variables, an alternative measure of human capital, and a
28
29 larger set of industries. In particular, we consider country characteristics which affect
30
31 industry specialisation such as income per capita, physical capital, financial
32
33 development, and the quality of institutions.

DATA

Country-industry data

The country-industry data used in this paper is taken from the EU KLEMS database³. From this database we obtain data on nominal gross value added, number of employees, total number of hours worked by employees and total and ICT real fixed capital stock for both manufacturing and non-manufacturing industries for a mix of one and two digit ISIC Rev. 3 classification over the period 1970-2005. The database contains information for the EU countries⁴ along with the United States (US), Canada, Switzerland, Australia, Japan and Korea. However, time coverage of the data series varies across countries: for EU countries before the EU enlargement of 2004 (EU-15) and US, Australia and Japan data is broadly available over the period 1970-2005, while for the new EU member countries (EU-10) coverage begins from 1995 onwards. Due to a limited number of observations we exclude countries from our sample for which data are only available post 1995. Thus, our sample includes 17 countries⁵ which are all open economies. We deflate the nominal gross value added using country-industry specific gross value added price indices provided in the dataset to obtain real gross value added. The dependent variables in our model specifications are average annual changes of real gross value added, of labour productivity and of employment over the period 1980 to 1999.

The country level human capital measure is average years of schooling taken from the Barro and Lee (2001) human capital dataset which provides average years of schooling data at five year intervals for the period 1960-1999. The country level initial stock of human capital (hc_{i,t_0}) is measured as the average years of schooling in 1980. Human capital accumulation ($\Delta hc_{i,T}$) is measured as the change in the average years of schooling between 1980 and 1999. We construct our cross country-industry

1 sample based on data covering the period 1980 to 1999⁶. We use information on ICT
2 capital stock for 29 non-overlapping one and two digit industries⁷.
3
4
5
6
7

8 *Industry-level data*

9
10 To investigate the effect of human capital on growth in ICT-intensive industries we
11 adopt the difference-in-difference approach taken by Rajan and Zingales (1998) and
12 contend that the effect of human capital on growth should vary depending on industry
13 level ICT intensity. Similar to other papers which use this approach, we use industry
14 data for US as a benchmark for industry characteristics (see for example Rajan and
15 Zingales 1998; Raddatz 2006; Ciccone and Papaioannou 2009; Bassanini et al. 2009).
16 Analogously, the key assumption underlying our benchmark approach is that for
17 technological and economic reasons some industries require more ICT capital than
18 others, and these differences persist across countries. The US is one of the most
19 flexible market economies and thereby enables firms to adjust their capital stock mix
20 closer to their desired level as they face lower barriers compared to firms in other
21 countries. We therefore contend that the ICT intensity of US industries is an
22 appropriate proxy for the underlying industry level ICT intensities. We compute the
23 ICT intensity of industries in the US as the share of industry fixed ICT capital in total
24 industry fixed capital stock.
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45

46 The validity of using the US industry ICT intensity as our benchmark can be
47 called into question on the grounds that institutional factors specific to the US may
48 impact on the ICT intensity rates in particular sectors and thereby cast doubt on
49 whether the US industry ICT intensity rates are a good measure of the cross-industry
50 differences in ICT intensities in other countries⁸. Before we proceed with our analysis,
51 it is therefore necessary to show that the US industry ICT intensity is an appropriate
52 benchmark and that the underlying assumption of the benchmark approach is valid.
53
54
55
56
57
58
59
60

1
2 To this purpose, we compare the distribution of ICT intensity of US and UK
3 industries in 1980 using the Spearman rank correlation index. We compare the US
4 with the UK as the UK is also one of the most flexible market economies in the world.
5
6 The Spearman correlation index between the US and UK industry ICT intensity rates
7
8 is high (0.54)⁹ suggesting that US industry's ICT intensities are not driven by
9 institutional characteristics specific to the US.
10
11

12
13
14
15
16 Further, we check that the distribution of ICT intensity across industries
17 remains stable over time. To this purpose, we compare the Spearman rank correlation
18 between the distributions of industry ICT intensity at five year intervals from 1980 to
19 2005. As shown in Table A2 in the Appendix, the distribution of ICT intensity across
20 industries in the US has remained relatively stable over time. The Spearman
21 correlation index between the intensity rates between 1980 and 1999 is quite high
22 (0.72).
23
24
25
26
27
28
29
30
31

32
33 Table A3 in the Appendix reports values of industry ICT intensity, human
34 capital intensity and physical capital intensity for all 29 industries. Industry human
35 capital intensity is defined as the share of hours worked by medium and high skilled
36 workers in total hours worked in an industry. Industry physical capital intensity is
37 computed as the share of fixed capital stock in total gross value added.
38
39
40
41
42
43

44
45 In our analysis we focus on a smaller sample of mainly manufacturing
46 industries. The reasoning for doing so is motivated by research which has highlighted
47 that mismeasurement of gross value added and productivity can be quite large in some
48 non-tradable sectors as well as in public sectors (see for example Nordhaus 2008;
49 Inklaar et al. 2008). The excluded industries are the following: Agriculture, hunting,
50 forestry and fishing; Real estate, renting and business activities; Mining and
51 quarrying; Sale, maintenance and repair of motor vehicles and motorcycles, retail sale
52 of fuel; Public administration and defence, compulsory social security; Coke, refined
53
54
55
56
57
58
59
60

1 petroleum products and nuclear fuel; Education; Health and social work; Other
2
3
4 community, social and personal services; Financial intermediation. In addition, given
5
6 its very large ICT intensity we exclude Post and telecommunication, to ensure that our
7
8 results are not driven by this outlier. In this restricted sample of 17 industries,
9
10
11 “Electrical and optical equipment” has the highest ICT intensity while “Construction”,
12
13 has the lowest ICT intensity.
14

15 16 17 18 *Country level data* 19

20 Our country-level measure of human capital is taken from the Barro and Lee (2001)
21
22 dataset. Our initial human capital measure is the average years of schooling in 1980.
23
24 The average years of schooling attained across the sample in 1980 was 7.5 years.
25
26 Table A4 shows the values for the country level initial human capital stock and for
27
28 human capital improvement used in our analysis. In 1980, Australia had the highest
29
30 level of human capital (10 years) while Portugal had the lowest (3.3 years). The
31
32 average change in the years of schooling across the sample of countries over the
33
34 period was 1.5 years. Korea experienced the greatest increase in the average years of
35
36 schooling (3.7 years) while Austria saw the lowest increase (0.4 years). As an
37
38 alternative measure of human capital we use the share of the population who have
39
40 completed secondary level education or have attained third level education. The
41
42 average share of the population with this level of education was 28% in 1980 with
43
44 Portugal exhibiting the lowest share, 8.1% and Sweden the greatest share, 51%.
45
46
47
48
49
50

51 Table A5 reports summary statistics for other country level variables used in
52
53 our analysis. The country level controls used in our analysis are taken from a number
54
55 of sources. Physical capital to GDP ratio is constructed using the real fixed capital
56
57 stock for total industries taken from EU KLEMS and is expressed as a share of real
58
59 GDP which is obtained from the World Economic Outlook Database. GDP per capita
60

1
2 is obtained from the World Development Indicators dataset of the World Bank. We
3
4 use two measures to control for financial development: domestic private credit as a
5
6 share of GDP (measuring the size of financial markets), obtained from the World
7
8 Development Indicators dataset of the World Bank and the stock market turnover
9
10 ratio (measuring the liquidity of stock markets relative to their size), taken from the
11
12 World Bank Financial Development and Structure Database (Beck et al. 2010). The
13
14 stock market turnover data is available from the late 1980s onwards and we therefore
15
16 use the value of stock market turnover ratio in 1990 in our analysis. Indices of the rule
17
18 of law and of regulatory quality are taken from the World Bank Governance
19
20 Indicators dataset (Kauffman et al 2009). We use the values of the indices in 1996 as
21
22 this is the first year for which data is available.
23

30

31 **EMPIRICAL RESULTS**

32
33
34 Table 1 reports the benchmark estimates of the relationship between human capital
35
36 and industry real gross value added growth. OLS estimates are shown in odd columns
37
38 and IV estimates are given in even columns. In the IV model specifications we
39
40 instrument human capital improvement over the period 1980-1999 with human capital
41
42 accumulation over the period 1970-1980. The exogeneity of the interactions with
43
44 human capital accumulation is rejected in all models. We focus our discussion on the
45
46 IV estimates.
47
48
49

50
51 [Table 1 about here]
52

53
54 Models 1-3 show the effects of human capital on industry growth conditioned only
55
56 on the initial level of gross value added. While in column 1 the coefficient of the
57
58 initial country human capital interacted with industry ICT intensity is not statistically
59
60 significant, it appears that human capital accumulation was associated with faster

1 growth of ICT intensive industries. As shown in column 3, the effect of the initial
2 human capital stock on the growth of ICT-intensive industries becomes significant
3 when we add to the model the interaction between human capital accumulation and
4 industry ICT intensity. This result is in line with findings by Krueger and Lindhal
5 (2001) and Aghion et al (2010). Models 4-7 include additional interactions to control
6 for other industry growth determinants. The positive and significant effects of both the
7 human capital stock and human capital accumulation on the growth of ICT-intensive
8 industries are robust to the inclusion of other determinants of industry growth. In
9 particular, the effect of human capital on ICT-intensive industries appears
10 independent of the effect of human capital on the growth of human capital-intensive
11 industries and the role of physical capital. The coefficient of the initial conditions is
12 negative and significant at 1 % level¹⁰.

13
14
15

17
18
19
20
21
22
23
24
25
26
27
28
29
30 To interpret the economic significance of the above mentioned estimates we
31 consider the growth differential between the industry at the 75th percentile of ICT
32 intensity (Transport equipment) and the industry at the 25th percentile of ICT intensity
33 (Wood and products of wood and cork) in a country with initial human capital stock at
34 the 75th percentile (Austria with 8.4 years) in comparison with a country with an
35 initial human capital stock at the 25th percentile (France with 6.8 years). The positive
36 and highly significant coefficient of the initial human capital interaction shown in
37 column 7 suggests that the annual growth differential between Transport equipment
38 and Wood and products of wood and cork was 0.6% in Austria in comparison with
39 France. The economic size of the effect of human capital improvement on growth in
40 ICT-intensive industries is larger. Thus, the implied annual growth differential
41 between the above mentioned industries is 0.9% in a country with human capital
42 accumulation at the 75th percentile (Finland with a human capital improvement of 1.8
43 years over the period) in comparison with a country with human capital improvement

1 at the 25th percentile (Denmark with a human capital improvement of 0.9 years).
2
3 Given that the countries analysed here are developed countries, differentials in human
4 capital stocks and human capital improvement are not sizable. It is therefore
5 worthwhile to look at growth differentials between the 90th percentile and the 10th
6 percentiles. In this latter case the implied annual growth differential between the
7 industry at the 90th percentile of ICT intensity (Machinery, not classified elsewhere)
8 and the industry at the 10th percentile (Rubber and plastic products) is 3.3% in a
9 country with human capital stock at the 90th percentile (Denmark with 9.2 years)
10 compared to the country with an initial human capital stock at the 10th percentile (Italy
11 with 5.3 years) and 4.1% in a country with human capital improvement at the 90th
12 percentile (Spain with 2.1 years) in comparison with a country with human capital
13 improvement at the 10th percentile (Australia with 0.6 years).

22
23
24
25
26
27
28
29
30

31 [Table 2 about here]
32

33 Table 2 shows the sensitivity of our benchmark estimates to additional country-
34 specific determinants of industry specialisation such as per capita income, physical
35 capital, financial development (we consider two measures of financial development:
36 the ratio of private credit to GDP - a measure of the size of financial markets and the
37 stock market turnover ratio - a measure of the stock market liquidity relative to its
38 size¹¹), and the quality of institutions (the rule of law and regulatory quality). Again
39 odd columns show the OLS estimates and even columns show the IV estimates. The
40 exogeneity of the human capital variables is rejected in all models with the exception
41 of the model controlling for the interaction between country stock market turnover
42 ratio and industry ICT intensity. The positive and highly significant effect of human
43 capital accumulation on the growth of ICT-intensive industries appears robust to all
44 additional country characteristics interacted with industry ICT intensity. The effect of
45 the initial human capital stock is positive and significant in all models with the
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2 exception of model 5 which includes an interaction of an index of the country level
3
4 rule of law and industry ICT intensity. In this latter case, the human capital stock
5
6 interaction with ICT intensity is positive but not significant. This finding together
7
8 with the positive and highly significant coefficient of the rule of law interaction
9
10 suggests that in countries with strong law contract enforcement, ICT-intensive
11
12 industries grew faster and the effect of the initial human capital stock on the growth of
13
14 ICT-intensive industries was not statistically significant over and above this effect. It
15
16 is also worth noting that in countries with a high initial human capital stock, and in
17
18 countries with a rapid human capital accumulation, human capital-intensive industries
19
20 grew relatively faster. The statistical significance of the coefficients of the interactions
21
22 between human capital accumulation and industry human capital intensity is lower in
23
24 comparison to the initial human capital stock interactions. The estimates shown in
25
26 Table 2 imply an annual growth differential between the 75th percentile industry and
27
28 the 25th percentile industry of 0.5% to 0.7% in Austria in comparison to France. In the
29
30 case of human capital improvement, the respective annual growth differential ranges
31
32 from 0.9% to 1.9% in Finland in comparison to Denmark.
33
34
35
36
37
38
39

40 Further, we check the sensitivity of our results to an alternative measure of
41
42 human capital, namely the share of the population over 25 years who have completed
43
44 secondary level education or have attained third level education. The OLS and IV
45
46 estimates of equation (1) and the sensitivity analysis to additional country
47
48 characteristics interacted with industry ICT intensity are shown in Table 3.
49
50

51
52 [Table 3 about here]
53

54
55 The exogeneity of the interactions with human capital accumulation variables is not
56
57 rejected when using this alternative measure of human capital. The OLS estimates are
58
59 qualitatively similar to those obtained with the previous measure of human capital.
60
The effect of the initial human capital stock on the growth of ICT-intensive industries

1
2 is positive and significant in all models with the exception of the model controlling
3
4 for the role of the stock market liquidity. The effect of human capital accumulation
5
6 remains positive and significant in all model specifications. The coefficients of the
7
8 interactions of human capital variables with industry level human capital intensity are
9
10 positive but no longer statistically significant.
11
12

13
14 Next, we extend our analysis to the effects of human capital on the growth of
15
16 productivity and employment.
17

18
19 [Table 4 about here]
20

21
22 Table 4 shows the OLS and IV estimates of the effect of human capital on the real
23
24 gross value added per hour worked by employees¹². The exogeneity of the human
25
26 capital variables is not rejected. The OLS estimates suggest that in countries with fast
27
28 human capital accumulation, labour productivity in ICT-intensive industries grew
29
30 relatively faster. This result is robust to the inclusion of controls for other country
31
32 characteristics interacted with the industry ICT intensity. The OLS estimates of the
33
34 effect of the country initial human capital stock are positive but not statistically
35
36 significant. Furthermore, the OLS estimates of the effect of human capital on the
37
38 labour productivity in human capital-intensive industries are not statistically
39
40 significant. The OLS estimates suggest that labour productivity growth differential
41
42 between the 75th percentile industry and the 25th percentile industry was from 0.3% to
43
44 0.7 % per annum in Finland in comparison to Denmark.
45
46
47
48
49

50
51 [Table 5 about here]
52

53
54 Table 5 shows the OLS and IV estimates of the effect of human capital on
55
56 employment growth. In this case, the exogeneity of the human capital variables is
57
58 rejected. The IV estimates indicate that in countries with fast human capital
59
60 accumulation, employment grew faster in ICT-intensive industries. The implied

1
2 annual employment growth differential between the 75th percentile industry and the
3
4 25th percentile industry was from 0.4% to 0.9% in Finland in comparison to Denmark.
5
6 This effect is statistically significant over and above the positive and statistically
7
8 significant effect of the initial human capital stock and human capital accumulation on
9
10 employment growth in human capital-intensive industries. The effect of the initial
11
12 human capital level on employment growth in ICT-intensive industries is also positive
13
14 but not significant in all models.
15
16

17
18 We finally re-estimate all regressions using a larger sample of industries.
19
20 Table 6 shows the OLS and IV estimates of equation (1)¹³ using a data set of 28
21
22 industries, all shown in Table A3 with the exception of Post and telecommunications,
23
24 a major outlier.
25
26

27
28 [Table 6 about here]
29
30

31
32 The results are broadly qualitatively similar to the results obtained with the smaller
33
34 number of industries. While the effect of human capital accumulation on labour
35
36 productivity growth in ICT-intensive industries appears positive and statistically
37
38 significant it is negative and statistically significant in the case of human capital-
39
40 intensive industries¹⁴.
41
42

43 44 45 46 **SUMMARY AND CONCLUSIONS** 47

48
49 This paper provides novel empirical evidence showing that the adoption of new
50
51 technology and human capital are complementary. In particular, we investigate the
52
53 effects of human capital on the growth of ICT-intensive industries using data from a
54
55 sample of open economies over the period 1980-1999. We focus on within country
56
57 between industry differences and control for country- and industry-specific effects
58
59 and a set of interactions between country and industry characteristics. In our model
60

1
2 specifications we account for the endogeneity of human capital improvement over the
3
4 analysed period.
5

6
7 Our econometric analysis suggest that value added and employment in ICT-
8
9 intensive industries grew faster in countries with a higher *ex-ante* human capital stock
10
11 and in countries with a fast improvement in human capital. Further, in countries with
12
13 fast human capital accumulation, labour productivity in ICT-intensive industries grew
14
15 faster. Our results are robust to controls for other determinants of industry growth and
16
17 factors affecting industry specialisation such as per capita income, physical capital,
18
19 financial development, and quality of institutions as well as to using alternative
20
21 human capital measures. The positive and statistically significant effect of human
22
23 capital on growth in ICT-intensive industries appears independent of the effect of
24
25 human capital on the growth of human capital-intensive industries documented by
26
27 Ciccone and Papaioannou (2009) and Hirsch and Sulis (2008). The effect of human
28
29 capital on the growth of ICT-intensive industries appears stronger in a data set of
30
31 mainly manufacturing industries in comparison to a larger number of industries
32
33 including services.

NOTES

¹ See Aghion and Howitt (1998) for a discussion of the theoretical literature on economic growth

² Results obtained with regressions where both the human capital stock and human capital accumulation are instrumented are qualitatively similar. These results are available from the authors upon request.

³ The March 2008 release available at: <http://www.euklems.net/euk08i.shtml>. O'Mahony and Timmer (2009) present a detailed description of the EU KLEMS database.

⁴ All EU countries without Bulgaria and Romania (EU-25): Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal Slovakia, Slovenia, Spain, Sweden, United Kingdom.

⁵ Australia, Austria, Belgium, Denmark, Spain, Finland, France, Germany, Greece, Ireland, Italy, Japan, Korea, the Netherlands, Portugal, Sweden, United Kingdom.

⁶ The period of over which we conduct our analysis ensures our results are comparable with Ciccone and Papaioannou (2009).

⁷ Real gross value added data is not available for Belgium's "Coke, refined petroleum and nuclear fuel" industry in 1980.

⁸ Bassanini et al. (2009) undertake a similar exercise to show that US industry layoff rates are an appropriate benchmark for the underlying layoff propensity in an industry.

⁹ A Spearman rank-order correlation test gives a significance level rejecting the null hypothesis of no correlation between the two series (p -value = 0.0026).

¹⁰ Our results are robust to the exclusion of this variable from regressions. We thank one anonymous referee for suggesting this sensitivity check. These results are available upon request from the authors.

¹¹ Existing empirical evidence suggests that economic growth is driven by the stock market liquidity rather than its size (see for example Levine and Zervos 1998; Beck and Levine 2004).

¹² We also estimated regressions using as dependent variable the real gross value added per employee. The results are broadly similar to those obtained with the gross value added per hour worked by employees as dependent variable. These results are available on request from the authors.

¹³ We also performed a sensitivity analysis to the inclusion of additional country characteristics interacted with industry ICT intensity. The results are qualitatively similar to those obtained with the

1
2
3 restricted number of industries. The size of the effects of the human capital on the growth of ICT-
4 intensive industries is smaller in comparison with those obtained with the smaller number of industries.

5
6
7 These results are available upon request from the authors.

8
9 ¹⁴ The positive effect of human capital accumulation on labour productivity in ICT-intensive industries
10 and a negative effect of human capital accumulation on labour productivity in human capital intensive
11 industries are also obtained when we include the Post and Telecommunications industry in the sample.

Notes: The dependent variable is the average annual growth of real gross value added at the country-industry level over the period 1980-1999. The initial country-level human capital (hc) is measured as the average years of schooling in 1980 and it is interacted with industry-level ICT intensity (ict intensity) and industry-level human capital intensity (hc intensity). The human capital accumulation (Δ hc) is the change in the average years of schooling at country level over the period 1980-1999 and it is interacted with industry ICT intensity and with industry human capital intensity. The physical capital interaction is obtained as the product between physical capital to GDP ratio at country level in 1980 (k/l) and industry physical capital intensity in 1980 (k intensity) measured as the ratio of industry fixed capital stock in total gross value added. Industry factor intensities are computed using data for the US. All models include the log of the gross value added (gva) in 1980 at the country-industry level. In the IV models human capital accumulation over the period 1980-1999 at country level is instrumented with the change in average years of schooling in each country for the period 1970-1980. Robust standard errors are shown in parentheses. Detailed definitions of variables and data sources are given in Table A1 in the Appendix.

Notes: The dependent variables are defined as follows: model (1): the average annual growth of real gross value added at the country-industry level over the period 1980-1999; model (2): the average annual growth of real gross value added per hour worked by employees at the country-industry level over the period 1980-1999; model (3): the average annual growth of the number of employees at the country-industry level over the period 1980-1999. The initial country-level human capital (hc) is measured as the average years of schooling in 1980 and it is interacted with industry-level ICT intensity (ict intensity) and industry-level human capital intensity (hc intensity). The human capital accumulation (Δ hc) is the change in the average years of schooling at country level over the period 1980-1999 and it is interacted with industry ICT intensity and with industry human capital intensity. The physical capital interaction is obtained as the product between physical capital to GDP ratio at country level in 1980 (k/l) and industry physical capital intensity in 1980 (k intensity) measured as the ratio of industry fixed capital stock in total gross value added. Industry factor intensities are computed using data for the US. All models control for initial conditions: as follows: in models (1) and (2): the log of the gross value added in at the country-industry level in 1980; in model (3): the log of the number of employees at the country-industry level in 1980. In the IV models human capital accumulation over the period 1980-1999 at country level is instrumented with the change in average years of schooling in each country for the period 1970-1980. Robust standard errors are shown in parentheses. Detailed definitions of variables and data sources are given in Table A1 in the Appendix.

Table A1. Variable definitions and data sources

Variables	Definition and Source
Country-Industry Specific	
$\Delta \ln y_{i,k,T}$	Average annual growth rate of real gross value added in industry k in country i over the period 1980-1999. Source: EU KLEMS.
$\Delta \ln emp_{i,k,T}$	Average annual growth rate of the number of employees in industry k in country i over the period 1980-1999. Source: EU KLEMS.
$\Delta \ln prod_{i,k,T}$	Average annual growth rate of labour productivity in industry k in country i over the period 1980-1999. Two measures of labour productivity are used: real gross value added per hour worked by employees and real gross value added per employee. Source: EU KLEMS.
$\ln y_{i,k,t_0}$	Natural logarithm of gross value added in industry k in country i in 1980. Source: EU KLEMS.
$\ln emp_{i,k,t_0}$	Natural logarithm of the number of employees in industry k in country i in 1980. Source: EU KLEMS.
$\ln prod_{i,k,t_0}$	Natural logarithm of labour productivity in industry k in country i in 1980. Source: EU KLEMS.
Industry Specific	
ict_{k,t_0}	ICT intensity computed as the share of ICT capital stock in total capital stock in industry k in the US in 1980. Source: EU KLEMS.
hc_{k,t_0}	Human capital intensity computed as the share of hours worked by high and medium skilled workers in total hours worked in industry k in the US in 1980. Source: EU KLEMS.
k_{k,t_0}	Physical capital intensity computed as the ratio of total fixed capital stock to total gross value added in industry k in the US in 1980. Source: EU KLEMS.
Country specific	
hc_{i,t_0}	Initial human capital stock. Average years of schooling in country i in 1980. Source: Barro and Lee (2001). We also use an alternative measure computed as the share of the population of over 25 years with completed secondary or attained tertiary education in 1980. Source: Barro and Lee (2001).
$\Delta hc_{i,T}$	Change in the average years of schooling in country i over the period 1980-1999. Source: Barro and Lee (2001). We also use an alternative measure computed as the change in the share of the population over 25 years with completed secondary or attained tertiary education over the period 1980-1999. Source: Barro and Lee (2001).
gdp_{i,t_0}	GDP per capita in country i in 1980. Source: World Development Indicators Database, the World Bank.
k_{i,t_0}	Physical capital to GDP ratio in country i in 1980 computed as the ratio of fixed capital stock in total industries in country i to GDP in country i. Source: EU KLEMS and the World Bank, World Economic Outlook Database.
$dcgdp_{i,t_0}$	Domestic credit to private sector to GDP ratio in country i in 1980. Source: World Development Indicators Database, the World Bank.
smt_{i,t_0}	Ratio of the value of total shares traded to average real market capitalization in country i in 1990. Source: Beck et al. (2010).
$rlaw_{i,t_0}$	Rule of law in country i. An index which measures "the quality of contract enforcement, the police, and the courts, as well as the likelihood of crime and violence" in 1996. Source: Kaufman et al. (2009).
$regq_{i,t_0}$	Regulatory quality in country i. An index which measures "perceptions of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development" in 1996. Source: Kaufman et al. (2009).

Table A3 reports values of industry characteristics in the US in 1980 that are used in our analysis. ict_{k,t_0} , hc_{k,t_0} , k_{k,t_0} denote ICT intensity, human capital intensity, and physical capital intensity respectively in industry k in 1980; ICT intensity is computed as the share of ICT capital stock in total capital stock. Human capital intensity is the ratio of hours worked by high and medium skilled workers in total hours worked. Physical capital intensity is the share of physical capital in total gross value added.

Table A4. Country level human capital

Countries	Average years of schooling, 1980	Change in average years of schooling, 1980 -1999	Share of population over 25 years with completed secondary or attained tertiary education, 1980	Change in the share of population over 25 years with completed secondary or attained tertiary education, 1980-1999
Australia	10.02	0.56	0.42	0.07
Austria	8.42	0.37	0.51	-0.05
Belgium	7.85	0.88	0.19	0.10
Denmark	9.16	0.93	0.47	0.14
Spain	5.15	2.11	0.13	0.17
Finland	8.33	1.81	0.41	0.16
France	6.77	1.61	0.21	0.19
Germany	8.41	1.34	0.33	0.07
Greece	6.56	1.96	0.21	0.18
Ireland	7.61	1.41	0.25	0.14
Italy	5.32	1.68	0.15	0.11
Japan	8.23	1.49	0.30	0.12
Korea	6.81	3.65	0.28	0.33
